Abstract

Our corpus of medieval French texts is divided into 59 discourse units (DUs) which cross text genres and spoken vs non spoken text chunks (as tagged with q and sp TEI tags). A correspondence analysis (CA) performed on selected POS tags indicates orality as the main dimension of variation across DUs. We then design several methodological paths to investigate this gradient as computed by the CA first axis. Bootstrap is used to check the stability of observations; gradient-ordered barplots provide both a synthetic and analytic view of the correlation of any variable with the gradient; a way is also found to characterize the gradient poles (here, more-oral or less-oral poles) not only with the POS used for the CA analysis, but also with words, in order to get a more precise and lexical description. This methodology could be transposed to other data with a potential gradient structure.

Keywords: textometry, Old French, represented speech, spoken genres, methodology, correspondence analysis, 1D model, data visualization, XML TEI, TXM software, DtmVic software.

1. Linguistic issue and preparation of textual data

We investigate spoken language features of Medieval French in a corpus composed of 137 texts (4 million tokens), taken from the Base de français médiéval¹. The corpus is annotated with part-of-speech (POS) tags at the word level; speech quotation chunks and speech turns are marked up using TEI XML tags at an intermediate level between sentences and paragraphs; and every text can be situated in a 32-genre typology (Guillot et al., 2017). Our hypothesis is that the features of orality may be related to text chunks representing speech, and also to text genres, as for instance some text genres are intended for oral performance. In order to perform a textometric analysis (Lebart et al. 1998) on our XML-TEI annotated data, we use the TXM open-source corpus analysis platform (Heiden, 2010; Heiden et al., 2010)².

We divide our corpus into 59 discourse units (DUs) obtained by splitting every genre into parts which represent speech on the one hand, and the remaining parts on the other hand (some text genres have no spoken passages). Discourse unit labels, like q_rbrefLn for instance, combine four pieces of information: (i) the first letter is either q for quoted speech

---

² Textometry Project and TXM software: http://textometrie.org
chunks, \textit{sp} for speech turns, or \textit{z} for remaining (non oral) chunks; (ii) then we have the short name of the text genre (here, \textit{rbref} means “récit bref”, i. e. short narrative); (iii) the uppercase letter stands for the domain\(^3\); (iv) the last character indicates whether this DU is represented in our corpus by one (1), two (2) or more (\textit{n}) texts.

We linguistically represent our texts with the POS tags\(^4\) they use\(^5\). The reliability of POS tags was measured in a previous study (Guillot et al., 2015) for a subset of 7 texts in which tags had been manually checked. For the present analysis, we eliminate low-frequency POS tags (freq. < 1 500), which include many high error rate tags and do not carry much weight into the quantitative analysis. For the remaining high error rate tags (with more than 25% wrong assignments), we measure their influence on the correspondence analysis (CA) by checking their contribution to the first axis. Then we remove the proper nouns category (NOMpro) which shows both high error rate and high contribution to the first axis (14.66%).

A new correspondence analysis enables two additional improvements from a linguistic perspective. We remove compound determiners (DETcom, PRE.DETcom, like \textit{ledit}) as they emerged at the end of the 13\textsuperscript{th} century, so that they introduce a singular and substantial diachronic effect (high contributions on the first axis). Moreover, the second axis describes mainly the association between psalms (\textit{z_psauitarRn}) and possessive adjectives (ADJpos): this corresponds to very specific phrases with some distinctive nouns (\textit{la meie aneme, li miens Deus, la tue misericorde}), and the adjective is equivalent to a possessive determiner in other contexts, so we merge the two categories (DETADJpos). We finally get a contingency table crossing 59 DUs with 33 POS tags to explore with a CA.

\section*{2. Linguistic and methodological results from correspondence analysis}

Our study reveals that the first axis can in fact be interpreted as an orality gradient. The factorial map (Fig. 1) shows \textit{z} \texttt{DUs} on the left hand side of the first axis, opposed to \textit{q} \texttt{DUs} and \textit{sp} \texttt{DUs} on the right hand side. Some genres intended for oral performance go to the right with speech chunks (especially plays –\textit{dramatiqueL}, \textit{dramatiqueR}), whereas genres related to written processing (especially practical acts (P): charters, etc.) go to the left with out-of-speech chunks. As this opposition matches the first axis, orality appears as the first contrastive dimension for Old French (as regards POS frequencies), as it is in Biber’s experiences with English (Biber, 1988), with the same kind of linguistic features (Table 1). Then, as a second result, DUs can be sorted according to their degree of orality, from “less oral” to “more oral” (see Appendix\(^6\)). Peculiar positions (for didactic dialogs or psalms for instance) can be explained by a formal use of language given by the rules of the genre. The linguistic analysis of the DU gradient is detailed in (Guillot-Barbance et al., 2017)\(^7\).

Using the First Axis of a Correspondence Analysis as an Analytical Tool

Figure 1. CA map of the 59 DUs (TXM). 21 DUs with low representation quality (cosine squared to 1 × 2 plane < 0.3) and no significant contribution to this plane (ctrb1 < 2 % & ctrb2 < 2 %) have been filtered out (macro CAfilter.groovy), so that the figure is clearer.

Figure 2. CA map of the 17 DUs with the largest confidence ellipses (DtmVic). The two largest ones (q_proverbesD2, q_lapidaireD2) couldn’t be drawn; the following three largest ones (q_commentaireD1, q_dialogueD2, q_sermentJ1) show that these DU positions cannot be interpreted; then other smaller ellipses indicate that the 54 remaining DU positions on axes #1 and 2 are stable.

Change is observed on gradient given by the first axis, according to the four zones defined by the analysis, except for a few points which are not related to this axis (low cosine squared).
Table 1. The eight POS with the highest contributions on the first axis, for both sides.

| “Less oral” pole                                    | “More oral” pole                                    |
|-----------------------------------------------------|-----------------------------------------------------|
| PRE preposition                                     | PROper personal pronoun                              |
| NOMcom common noun                                   | ADVgen general adverb                                |
| PRE.DETdef preposition + definite determiner         | ADVneg negative adverb                               |
| VERppe past participle                               | VERcig finite verb                                   |
| DETdef definite determiner                           | PROadv adverb (en, y)                                |
| DETcar cardinal determiner                           | DETADJpos possessive determiner or adjective         |
| VERppa present participle                            | CONsub subordinating conjunction                     |
| CONcco coordinate conjunction                        | VERinf infinitive verb                               |

A bootstrap validation (Dupuis & Lebart, 2008, Lebart & Piron, 2016) is applied to evaluate the stability of DU positions on the first axis (Figure 2). Sizes of ellipses in the 1×2 map are correlated to sizes of DUs: the fewer the words there are in the DU, the less data the statistics process, and the greater is the confidence ellipse (Table 1). Only five DUs are ascribed a big ellipse which shows their uncertain position (Figure 2): all of them are DUs from about ten words to about a hundred words, which are DUs for very singular linguistic usages, and are neither representative nor relevant for this overall linguistic analysis. The orality gradient is then confirmed throughout a statistic validation on our data.

The 2D factorial map provides a synthetic and efficient visualization. The second axis display reveals that the “more oral” pole is more compact, more consistent, than the “less oral” pole, which is more heterogeneous (the cosine squared values corroborate this). But what we want to stress in this methodological paper, is that the main linguistic result is uniquely provided by the interpretation of the first axis. Benzécri has illustrated the same kind of approach by using a 1D CA to reveal the hierarchy of characters in Racine’s Phèdre (1981 : 68). This method emphasizes the analytic power of CA, which separates the data (by the mathematical means of Singular Value Decomposition) into “deep” components (factors), just as a prism breaks light up into its constituent spectral colors. Despite its main use as a 2D illustration of a corpus structure in the textual data analysis field, CA is much more than a suggestive visualization or a quick sketch.

3. Complementary tools to analyse 1D gradient in textual data

We now test new means to gain insight into the causation of this gradient in our data.

3.1. Gradient-ordered barplot

![Figure 3. Gradient-ordered specificity barplot for Personal Pronoun, as example of a POS which is correlated to the first axis. For readability reasons, the height of specificity bars is limited to 20.](image)

The first method we propose is to visualize the evolution of POS frequencies according to the orality gradient using a specificity bar-plot chart where the DU order on the x-axis is given by...
the DU order on the first CA axis: this display visually reveals how much a POS is correlated with speech or non-speech features, and details its affinity with each DU. For instance, personal pronouns are typical for the more-oral pole: this is displayed as a rising profile (Figure 3), and one can easily find out which DU have an outlying use of this POS. Whereas a POS like adjectives (Figure 4), which is not correlated to the orality gradient, gets a chart with no overall pattern.

Figure 4. Gradient-ordered specificity barplot for adjectives, as example of a POS which is not correlated to the first axis. For readability reasons, the height of specificity bars is limited to 20.

3.2. Back-to-text close reading by getting representative words for each side of the first axis

The second methodological innovation concerns obtaining lexical information about orality characteristics in our texts. We select two sets of DUs based on their cosine squared scores for the first CA axis in order to represent the more-oral ($\cos^2 1 > 0.4$) and less-oral ($\cos^2 1 > 0.35$) poles (Table 2). The $\cos^2$ thresholds are adjusted to get two balanced sets with enough different DUs to get an adequate representativeness. Then, a specificity computation, which statistically characterizes the distribution of words into these two sets, reveals lexical features for more oral and less oral poles, showing typical words as they can be read in texts. Light is thus shed on the quantitative result through qualitative observations.

Table 2. Representative DUs

| _ADJqua_ | _mel_ | 160   | 160  | 0.25  | 0.25  |
| _ADJqua_ | _bele_ | 98    | 98   | 0.25  | 0.25  |
| _ADJqua_ | _mortelle_ | 97    | 97   | 0.25  | 0.25  |
| _ADJqua_ | _bel_ | 250   | 250  | 0.25  | 0.25  |
| _ADJqua_ | _been_ | 88    | 88   | 0.25  | 0.25  |
| _ADJqua_ | _meilleur_ | 67    | 67   | 0.25  | 0.25  |
| _ADJqua_ | _las_ | 100   | 100  | 0.25  | 0.25  |

Our example sheds light on the uses of adjective: whereas adjectives are not related to the orality gradient as a category (Figure 4), they have strong associations at a lexical level (Table 3). Represented speech makes much use of terms of address introducing speech turns (bel, douz – and their formal variants: biaus, biax, etc.), and evaluative adjectives (grant, mal, been). For the less-oral pole, there are more POS tagging errors; adjectives are more diverse.
and often associated with a subset of DUs, for instance present, saint, maistre are typical of two texts.

4. Conclusion

In this contribution, we have shown several ways to take into account the limits of real data, especially textual data: managing the POS tags reliability (§1), validation process to identify where data is lacking (§2), refining morphosyntactic based analysis with lexical information (§3). But our main objective is to establish a methodology in order to reveal and study any gradient-like deep structuration of data. A simple seriation (as illustrated in Dupuis & Lebart, 2008) could provide the same results for the first step, as it generates the same ordered view of the data. But CA gives much more information, qualifying the relation of each variable to the gradient with indicators like contributions and cosines squared. Interpretation can go further: CA coordinates are controlled with bootstrap and confidence ellipses, gradient-ordered barplot visualizations are efficient to analyse in detail the relationship of any individual variable to the overall gradient, and the gradient poles can be illustrated by words, which add a concrete and textual account for the deep structure. Thus, on our corpus of French medieval texts, we discover that orality is the main contrastive dimension and that it characterizes represented speech as well as text genres. The methodology could be applied to other data, and is already entirely implemented using tools freely available to the scientific community.

This research has benefited from the PaLaFra ANR-DFG project (ANR-14-FRAL-0006), for corpus extension and POS evaluation. We are also very grateful to Ludovic Lebart, for his inspiring comments on a preliminary presentation of this research, and for DtmVic software, which has evolved in order to take into account the quantitative particularities of our data.
