Renewable Energy Challenges and Opportunities in the Kingdom of Saudi Arabia

Mohammed Al Yousif *

Department of Economic Research, Acharya Narendra Dev College, University of Delhi, New Delhi, India

ABSTRACT

This paper seeks to introduce a different method of investing in renewable energy, one that will be more attractive to local investors. It concludes that investment in renewable energy is a promising strategy for creating more sustainable jobs for Saudi citizens and promoting the domestic economic diversification. The Saudi renewable energy sector shall increase the contribution that the Saudi non-oil sector makes to the total Saudi economic activities. Further development of the Saudi renewable energy sector should encourage further domestic energy consumption efficiency and less pollution. However, challenges typically thwart progress in the renewable energy sector. These challenges include technical problems, cost issues and lack of financial sources. This paper proposes solutions that should help circumvent these particular challenges.

Keywords: Renewable energy, Input-output table, Value Added, Saudi Arabia, Energy efficiency, Diversification, Less pollution, Sustainable jobs

INTRODUCTION

By the end of 2018, Saudi Arabia was consuming for domestic energy usage more than three million barrels of oil every day; among these, 0.5 million barrels were solely for desalination. Moreover, the demand for water and energy is expected to increase significantly in Saudi Arabia due to high population growth (approximately 3.2% annually in recent years) and economic growth. The total number of oil barrels used inside the Kingdom part essential is predicted to be around eight million per day by the end of 2050. This current level of domestic consumption of energy places a heavy burden on the government budget and prevents the exploration of opportunities to export more barrels of oil. However, renewable energy investments there are many are the would increase the demand for domestic economic activities such as construction, manufacturing, services and utilities, as well as the activities of small and medium enterprises (SMEs), which should help generate more jobs for Saudi citizens.

Therefore, this research’s objective is to propose a transformation roadmap for the Saudi economy so that it achieves a higher level of diversification and more sustainability. In conclusion, this paper will discuss, specifically, the challenges and opportunities of investment in the renewable energy sector, renewable energy technology and the Saudi renewable energy contribution to the local production system, the labor market and the value added.

LITERATURE REVIEW

Challenges and Opportunities for Widespread Renewable Energy Development

Investment in renewable energy has faced many challenges worldwide, such as those of financial and technical natures, as well as a small market share. Renewable energy technology, maintenance, and training are still very costly compared to conventional sources of energy. Thus, the share of renewable energy as compared to total energy was no greater than 12% worldwide and less than 10% in the United States in 2017. In addition, the challenges related to investment in renewable energy in Saudi Arabia include high temperatures and significant amounts of dust, which are not appropriate for photovoltaic (PV) and concentrated solar power (CSP) technologies. The efficiency of PV systems is found to decrease at high temperatures, while dust reduces the output level of reflectors, especially of the CSP system. However, the addition of cooling and washing systems could solve these problems.

In summary, renewable energy development faces various challenges, such as technological issues, the high initial cost of renewable energy projects, low efficiency, and a shortage of funding.

On the other hand, investment in renewable energy is an effective policy for generating more jobs for the local community and promoting domestic economic activities. Additionally, the use of
renewable energy, even if only partially, should help reduce the level of pollution and increase the level of environmental quality.

Renewable Energy Technology

The types of renewable energy technologies handled by this research are solar energy (Photovoltaic [PV], Concentrated Solar Power [CSP], and wind energy). This research focuses on these types of technologies because it seems that they are more suitable for Saudi Arabia’s weather and geography. As discussed, solar energy has two essential parts: Photovoltaic (PV) and Concentrated Solar Power (CSP). Solar photovoltaic (PV) technology is the dominant technology for generating renewable energy because it is very efficient and easy to install. The other kind of technology, such as CSP, is excellent on a large scale for producing electricity in cities. CSP technology could be used for desalination as well as for generating electricity on a big scale. Wind technology is also considered as a cheap source of renewable energy worldwide.

Solar energy

The Middle East region receives around 3,000-3,500 hours of sunshine per year, with over 2500 kWh/m² of solar energy per day. Saudi Arabia has additional potential part of the source to for investment in solar energy because it has the Empty Quarter, which can host a solar array, and clear sand, which can be used to manufacture silicon PV cells and mirrors (Aksakal & Rehamm, 2009). Solar PV technology uses semiconductor materials to convert solar energy directly into electricity. Besides, solar PV can be used in small-scale projects, and it does not require a large area. Saudi Arabia could use solar PV technology in remote areas because these small villages need a limited amount of electricity, such as for water pumps and lighting. In addition, solar PV energy can be used for road lights, road instructor signals, tunnel lighting, and traffic lights. Concentrating Solar Power systems (CSPs) technology uses mirrors to concentrate solar energy by 50 to 10,000 times. This heat creates steam for moving turbines and generating electricity. The CSP requires many laborers (especially during construction) and machinery due to an increased demand for glass, iron, and other materials (Asplund, 2008).

Wind energy

Wind energy is expected to be the dominant source of renewable energy because it has a faster growth rate compared to other types of renewable energy. The main advantages of wind energy are clean and less polluting. Some negative effects on the environment of using wind energy are killing some birds and destructing some forest (Iskander, 2015). Saudi Arabia has many attractive areas for producing wind energy, particularly around the Arabian Gulf and the Red Sea coastline zones.

The Contribution of Saudi Energy Efficiency and Renewable Energy to Saudi Arabia (GDP, Labor Market, and Value Added)

The Saudi economy would gain many benefits from increasing domestic investment in renewable energy. These new renewable energy investments expected to augment the domestic economic growth. Investment in renewable energy predict to enhance significantly various sectors of the economy, such as construction, services, and research and development (R&D). This paper estimates and calculates the contribution of investment in Saudi renewable energy to the Saudi economic activities, value-added and the labor market by using Leontief’s input-output model (Chemingui & Lofgren, 2004; Al-Hawwas, 2010).

As long as the renewable energy sector has higher value-added activities and uses input materials from most economic sectors, investment in renewable energy should generate more expansion on a big list of domestic economic activities due to new investments in renewable energy. Any expansion on a domestic production system shall increase the demand for laborers. In 2019, the International Renewable Energy Agency (IRENA) estimated the number of (direct and indirect) jobs in renewable energy worldwide during the period between 2017 and 2018. There were approximately more than 10.3 million jobs in renewable energy worldwide in 2013 and 11.0 million in 2018. According to IRENA, the higher number of renewable energy jobs can be found in Germany, China, Brazil, India, the United States, and Japan. There is a wide range of occupation in renewable energy, such as engineering, technicians, marketing, retail, administration and customer service. Jobs in renewable energy could be classified into different fields such as research and development, manufacturing and distribution; project development; construction and installation; and operation and maintenance.

RESULTS & DISCUSSION

The main purpose of using Leontief input-output model as a methodology for this research is to study the contribution of investment in renewable energy to the other sectors of production. A macroeconomic input-output model is a quantitative tool for calculating the rate of growth resulting from increased investment in renewable energy (Pestel, 2014). The input-output model has a high capability of capturing the flow of goods and services between different sectors of production. Furthermore, this model captures the flow stream of goods and services in the economy as a whole. The purpose of calculating this new expansion in the production system is to estimate the further additional increase in demand for goods, services, and labor due to the flow of investment in renewable energy. The input-output model traces economic activities as a process of interrelations among different sectors of production and the final demand entities. Thus, the input-output model considers the circulation of inputs of raw materials (or services) and outputs of finished or semi-finished goods (or services) among different sectors of production and the final demand sector. Overall, the Leontief approach has the ability to calculate the tradeoff coefficient between different domestic entities of production and the final demand (government, investors, household consumption and trade) (Miller, 2009).

The sizes of interchangeability between the production sectors depend on the tradeoff coefficient between domestic entities of production and the final demand (government, investors, household consumption and trade) (Miller, 1998). The tradeoff coefficient means the distribution of sector A output to other sectors of production, which could be read as ai_j/ai. According to table (3) Saudi Arabia A’ matrix input-output, the tradeoff coefficient of Agriculture Act (1) to Construction Act (7) is around ab/aa = 0.32, or 32 percent of Agriculture production consumed directly by Construction sector. Any investment increase in sector Act (7) would result in a new expansion of the production of Agriculture sector Act (1). This increase in production of Act (7) would increase the demand on all kinds of inputs. In our example, the demand increase from Act (7) will be distributed to other sectors of production in the existing economic system; one of them is increasing the demand on Act (1) outputs.

According to Miller and Blair (2009), Leontief’s input-output
model can simulate the forward and backward connections between the domestic production sectors and the final demand sectors. It is a backward and forward movement that any expansion in sector B would push forward the demand on the other sectors of production and import. Some output of sector B is input to other sectors of production such as A, C, D, which there demand on the other sector of production would increase as a backward effect. In the end, the whole system of production shall expand because of expanding investment in B. The Leontief model is eligible for calculating this kind of dynamic movement in the model. These calculations are intended to help us estimate the amount of expansion in the economic system due to increasing investment in renewables.

The main purpose of using this particular methodology is to study the contribution of investment in renewable energy to the other sectors of production. As long as the renewable energy sector has a high level of diversification, investment in renewable energy should generate more expansion on a big list of domestic economic activities due to new investments in renewable energy. Any expansion on a domestic production system shall increase the demand for laborers.

This calculation helps us to estimate the amount of expansion in the entire economic system because of increased investment in renewables. The Leontief table divides the national economy into n+1 sectors, which can be grouped into two major categories: one is the producing sector, and the other is the final demand sector, which can be further divided into sub-groups (government spending, household consumption, investment and net exports). Hence, the total output of any sector of production will either be in the form of an intermediate input to both itself and the other sectors of production or it will go to the final demand sector, which consumes the rest of these outputs. Therefore, the total goods and services produced by a particular production sector should be consumed by the n sectors of production and the n+1 sector (the final demand sector). In short, the input-output model reveals the flow of goods and services among all economic production sectors and the consuming sector (which is further sub-divided into the final components of expenditure GDP) over a period of time, usually one year. The Saudi input-output table is divided into three essential sectors (domestic consumption sector, value-added sector, final uses) as it appears in figure (1).

Table (1) provides a snapshot of the Saudi input-output table (2015). Table (1) contains three areas with different colors. Area number (1) (in red) contains information about trade between the sectors of production (in value “Million of SR”). Area (1)'s columns represent the supply side, for instance, the total output of the agriculture sector that is consumed by the agriculture sector, manufacturing and wholesale and retail trade. The other side of the matrix is the raw side, which includes the total demand of each sector of production. Area (2) (in blue) contains the final government and household consumption of the three sectors of production. Area (3) (in brown) includes the value added by each sector of production. The primary data were collected from different sources, including the Organization for Economic Co-operation and Development (OECD), the General Authority for Statistics (GSTAT), and the Saudi Arabian Monetary Authority (SAMA). In addition, some information obtained from the Saudi National Transportation Plan (NTP 2020), Saudi Vision (Vision 2030), and any announcement by the Public Investment Fund (PIF). This research used the Leontief’s I-O model as a quantitative method for calculating the expected economic growth from new investments in renewable energy at Saudi Arabia (Al Yousif & Albaker, 2017).

Table 1: The Saudi Arabian Input-Output Table (2015).

| GDP Activities | Agri-culture | Wholesale & Retail Trade, Restaurants & Hotels | Final Consumption Expenditure by Government | Final Consumption Expenditure by Households |
|---------------|-------------|---------------------------------------------|---------------------------------|---------------------------------|
| Agriculture   | 7,928       | 880                                         | 5,548                           | 2,142                           | 39,097                          |
| Manufacturing | 9,631       | 19,404                                      | 141,391                         | 1,355                           | 372,167                         |
| Wholesale & Retail Trade, Restaurants & Hotels | 4,952 | 14,178 | 0 | 71,848 |
| Compensation of Employment | 8,302 | 45,195 | 55,423 | 212,346 |
| Operating Surplus | 60,404 | 202,153 | 212,346 |  |
in the domestic production system, the expected additional growth in the value added and the estimated number of new jobs (direct and indirect).

The expected expansion of investment of 25 billion Saudi Riyals in the domestic production system growth is no less than 2.4 percent; see. The establishment of a new project in renewable to the energy will create new demand for different sectors of production. Some sectors of production are expected to expand in response to this new demand. Moreover, the impact of new investment in renewable energy was distributed among the sectors of production based on the level at which these production sectors were involved in the renewable energy sector. Also, the Saudi government could enhance the domestic producers to meet the new demand from the domestic renewable energy projects. Thus, this new investment in renewable energy should be distributed to different sectors of production based on their levels of involvement in renewable energy activities. It contains the distribution of Saudi sectors of production.

Based on the expected expansion in the whole domestic to be the system of production is estimated to be around 6.0 percent of an investment of 25 billion Saudi Riyals. The distribution of the investment of 25 billion Saudi Riyals in renewable energy has been resolved using the Leontief’s inverse matrix (X-A)1. The equation (ΔX=(i-Δg)* Δg summarizes the following changes between different sectors of production through the Leontief’s inverse matrix (X-A)-1. If the government had invested one billion dollars in enhancing the renewable energy activities in the Kingdom, this amount of investment would have flowed directly to the construction and manufacturing sectors. Any new investment in the domestic renewable energy sector would have a lower impact on the financial, insurance, real estate, restaurant, hotel, and transportation sectors, as well as on all other business services.

From the total value added is estimated to be around 2.7 to be the percent of the investment of 25 billion dollars in renewable energy. As is clear from to be the, there are three main sources of value added: ‘Compensation of Employment,’ ‘Taxes Minus subsidies,’ and ‘Operation Surplus.’ The same methodology was used to calculate the new value added and the change in the production system resulting from the investment of 25 billion, 50 billion, and 85 billion Saudi Riyals in renewable energy. There is an expectation that value added will increase by to be around 4.7 percent and 6.0 percent for an investment of 50 billion and 85 billion Saudi Riyals. Shows the expected number of the new jobs that would be generated in all three scenarios, i.e., 44,000, 90,000, and 150,000 thousand jobs.

CONCLUSION

Investment in renewable energy inside the Kingdom of Saudi Arabia has many economic benefits. The primary hypothesis of this research is "investment in renewable energy is an optimal solution for solving various kinds of problems, such as unemployment and less economic diversification.” Most of renewable energy empirical research papers concluded that investment in renewable energy is a very promising solution for generating more jobs and driving economic growth. There are numerous benefits of investment in renewable energy, including creating more jobs for Saudis, making new sources of income and reducing the domestic consumption of fossil fuel and saving more oil for export.

This study has calculated three multipliers: labor, value-added, and output. The output multiplier of investment in the Saudi renewable energy sector is estimated to be around 8 percent. This means that increasing demand for the renewable energy sector by SAR 1 million is expected to increase the total economic demand, on average, by SAR 80 thousand. The value-added multiplier is estimated to be around 4 percent, which means that an investment of SAR 1 million in Saudi renewable energy will generate SAR 40 thousand value-added. Regarding to labor multiplier, there are 1,750 new permanent direct jobs expected to be made from each SAR 1 billion spent on renewable energy in Saudi Arabia.

Overall, this research encourages the Saudi government to actively invest in the renewable energy sector and localize relevant supply chains. Some can argue that it is cheaper to import renewable energy equipment and machines from abroad, because localizing renewable energy industries could increase the cost of renewable energy.

However, localizing renewable energy production could be a promising approach for creating more work opportunities for Saudi citizens through three channels (direct, indirect, and induced). Direct jobs would be mostly in project development, construction, installation and maintenance. Indirect jobs would be available in other manufacturing sectors supplying the renewable energy sector and financial sector, including the banking system, with equipment, materials and services. Employees of these new renewable energy sector projects would ultimately generate induced jobs through the new expenditures on local goods and services. This new demand will lead to an expansion in the local businesses and social activities, such as groceries, hospitals, schools and restaurants. Further research could be explored by investigating the economic benefit of solar energy or wind energy.
