Maximal prime homomorphic images of mod-$p$ Iwasawa algebras

Billy Woods

January 18, 2018

Abstract

Let $k$ be a finite field of characteristic $p$, and $G$ a compact $p$-adic analytic group. Write $kG$ for the completed group ring of $G$ over $k$. In this paper, we describe the structure of the ring $kG/P$, where $P$ is a minimal prime ideal of $kG$. We give an isomorphism between $kG/P$ and a matrix ring with coefficients in the ring $(k'G')_\alpha$, where $k'/k$ is a finite field extension, $G'$ is a large subquotient of $G$ with no finite normal subgroups, and $(-)_\alpha$ is a "twisting" operation that preserves several desirable properties of the ring structure. We demonstrate an application of this isomorphism by setting up correspondences between certain ideals and subrings of $kG$ and those of $(k'G')_\alpha$, and showing that these correspondences often preserve some useful properties, such as almost-faithfulness of an ideal, or control of an ideal by a closed normal subgroup.

Introduction

Let $G$ be a compact $p$-adic analytic group, and $k$ a finite field of characteristic $p$. Write $kG$ for the completed group ring of $G$ over $k$,

$$kG := \lim_{\leftarrow} k[G/N],$$

where the inverse limit ranges over all open normal subgroups $N$ of $G$, and $k[G/N]$ denotes the ordinary group algebra of the (finite) group $G/N$ over $k$.

In this paper, we explore the structure of the ring $kG/M$, where $M$ is an arbitrary minimal prime ideal of $kG$. It is known already, due to Ardakov [2], that the minimal primes of $kG$ are intimately connected with the minimal primes of $k\Delta^+$, where

$$\Delta^+ = \{ x \in G \mid o(x) < \infty, [G : C_G(x)] < \infty \}$$

is the finite radical of $G$. We review this connection in Lemma 1.1.

Our first result is:

**Theorem A.** Let $H$ be a compact $p$-adic analytic group with $H/\Delta^+$ pro-$p$, and let $k$ be a finite field of characteristic $p$. Take a minimal prime $p$ of $k\Delta^+$ which is $H$-invariant, so that $pkH$ is a minimal prime of $kH$. Then there exist a positive integer $t$, a finite field extension $k'/k$, and an isomorphism

$$\psi : kH/pkH \rightarrow M_t\left(k'[\![H/\Delta^+]\!]\right).$$

This is a strengthening of the results in [2] Propositions 10.1, 10.4] and [2], which deal only with simple cases such as the case when $H = F \times U$, for $F$ a finite group and $U$ a uniform pro-$p$ group.

In the proof of this theorem, as elsewhere in this paper, we give a reasonably explicit construction of such an isomorphism, so as to be able to keep track of images of ideals and subrings.

In general, if $G$ is a compact $p$-adic analytic group, $G$ will have an open normal subgroup $H$ satisfying the conditions of Theorem A; but this may not in general extend to an isomorphism

$$kG/pkG \rightarrow M_t\left(k'[\![G/\Delta^+]\!]\right).$$

However, this is not too far off. We show that a similar result does hold, provided we are willing to replace $k'[\![G/\Delta^+]\!]$ by a closely related ring $(k'[\![G/\Delta^+]\!])_{\alpha}$, a central 2-cocycle twist of $k'[\![G/\Delta^+]\!]$. We define this fully in Definition 5.4 and then show that the twisting process $(-)_{\alpha}$ preserves some desirable properties.

**Theorem B.** Let $G$ be a compact $p$-adic analytic group and $H$ an open normal subgroup containing $\Delta^+$ with $H/\Delta^+$ pro-$p$, and let $k$ be a finite field of characteristic $p$. Take a minimal prime $p$ of $k\Delta^+$ which is $G$-invariant (note that then
\( p kH \) is a minimal prime of \( kH \) and \( pkG \) is a minimal prime of \( kG \). Then the isomorphism \( \psi \) of Theorem A extends to an isomorphism
\[
\tilde{\psi} : kG/pkG \to M_t(\langle k'[G/\Delta^+] \rangle)_{\alpha}.
\]

Studying this isomorphism in detail allows us to understand the behaviour of ideals of \( kG \) containing \( pkG \) by understanding ideals of \( \langle k'[G/\Delta^+] \rangle \) \( \alpha \). We derive some consequences of Theorem B that will be useful in later work.

In Definition 1.4 below, we will say that an ideal \( I \) of \( kG \) is faithful if the natural map \( G \to (kG/I)^\times \) is an injection, and almost faithful if its kernel is finite. A measure of the failure of \( I \) to be faithful is given by the normal subgroup \( I^\perp := \ker(G \to (kG/I)^\times) \).

**Theorem C.** With notation as in Theorem B, let \( A \) be an ideal of \( kH \) containing \( pkH \). Write \( \psi(A/pkH) = M_t(\alpha) \) for some ideal \( \alpha \) of \( k'[G/\Delta^+] \). Then

(i) \( A \) is prime in \( kH \) if and only if \( \alpha \) is prime in \( k'[G/\Delta^+] \).

(ii) \( A \) is stable under conjugation by \( G \) if and only if \( \alpha \) is stable under conjugation by \( G/\Delta^+ \) in the ring \( \langle k'[G/\Delta^+] \rangle \) \( \alpha \).

(iii) \( A \) is almost faithful as an ideal of \( kH \) if and only if \( \alpha \) is (almost) faithful as an ideal of \( k'[G/\Delta^+] \).

We state all of these results together here for convenience. Statement (i) above is an easy consequence of Morita equivalence, given in Lemma 1.7, but statements (ii) and (iii) rely crucially on explicit calculations under the isomorphism \( \psi \).

In the general case, \( p \) will not necessarily be \( G \)-invariant, but may have a (finite) \( G \)-orbit, say of size \( r \). In this case, we have:

**Theorem D.** Let \( Q \) be a minimal prime ideal of \( kG \), and let \( p \) be a minimal prime ideal of \( k\Delta^+ \) containing \( Q \cap k\Delta^+ \). Then there is an isomorphism
\[
kG/Q \to M_{rt}(\langle k'[G_1/\Delta^+] \rangle)_{\alpha},
\]
where \( G_1 \) is the open subgroup of \( G \) stabilising \( p \).

We prove a much more precise statement of this theorem in section 6, but do not state it here as the notation is rather technical. The more precise statement helps in understanding the relationship between ideals of \( kG \) and ideals of \( kH \), when \( H \) is a closed normal subgroup of \( G \). When \( H \) acts transitively on the \( G \)-orbit of \( p \), as in the special case of Theorem B, it is not hard to generalise Theorem C; but the \( G \)-orbit of \( p \) may split into several \( H \)-orbits, possibly of different sizes, and it is important to keep track of the isomorphism.

As an application of this, we finally prove the following result:

**Theorem E.** Let \( P \) be an ideal of \( kG \), and suppose that \( P \cap k\Delta^+ \) is contained in each of the minimal prime ideals \( p_1, \ldots, p_n \) of \( k\Delta^+ \), which are all transitively
permuted by $G$ under conjugation. Let $H$ be any closed normal subgroup of $G$ containing $\Delta^+$. For each $1 \leq i \leq n$, let $G_i$ be the (open) stabiliser in $G$ of $p_i$, and note that $G_i$ must contain $\Delta^+$. Then we can find an ideal $Q_i$ of $k^\prime G_i$ for each $1 \leq i \leq n$ such that the following properties hold:

(i) each $Q_i \cap k\Delta^+$ is contained only in the minimal prime ideal $p_i$ of $k\Delta^+$;

(ii) $P$ is controlled by $H$ if and only if each $Q_i$ is controlled by $H \cap G_i$; and

(iii) $P^\dagger = \bigcap_{i=1}^{n} Q_i^\dagger$.
1 Preliminaries

Recall the FC-centre $\Delta(G)$ and the finite radical $\Delta^+(G)$ from [12, Definition 1.2]. We will often write $\Delta = \Delta(G)$ and $\Delta^+ = \Delta^+(G)$ as shorthand throughout this paper.

We record here, for ease of reference, some facts and notation that we will use throughout this paper.

Lemma 1.1. Let $G$ be a compact $p$-adic analytic group, and $k$ a finite field of characteristic $p$.

(i) Write $J := J(k \Delta^+)$. Then $JkG$ is a two-sided ideal of $kG$ contained in the prime radical of $kG$. Hence, denoting by $\langle \cdot \rangle$ images under the natural map $kG \to kG/JkG$, there is a one-to-one correspondence

$$\{\text{minimal prime ideals of } kG\} \longleftrightarrow \{\text{minimal prime ideals of } kG/JkG\}.$$

(ii) Retain the notation of (i).

Let $X = \{e_1, \ldots, e_r\}$ be a $G$-orbit of centrally primitive idempotents of $k \Delta^+$, and write $f = e_1 + \cdots + e_r$. Then $M_X := (1-f)kG$ is a minimal prime ideal of $kG$, hence (by (i)) its preimage $M_X$ in $kG$ is a minimal prime ideal in $kG$.

Conversely, let $M$ be a minimal prime ideal of $kG$. Then there exists a $G$-orbit $X$ of centrally primitive idempotents of $k \Delta^+$ such that $M = M_X$.

This sets up a one-to-one correspondence

$$\{\text{minimal prime ideals of } kG\} \longleftrightarrow \{\text{G-orbits of centrally primitive idempotents of } k \Delta^+\}.$$

(iii) Given a centrally primitive idempotent $e \in k \Delta^+$, there exists some $t > 0$ and some finite field extension $k'/k$ with $e \cdot k \Delta^+ \cong M_t(k')$. Hence, if $A$ is a $k$-algebra, we may identify the rings

$$e \cdot k \Delta^+ \otimes_k A \cong e \cdot k \Delta^+ \otimes_k (k' \otimes A) \cong M_t(k' \otimes A).$$

Proof.

(i) This follows from [2, 5.2].

(ii) This follows from [2, §5, in particular 5.7].

(iii) $e \cdot k \Delta^+$ is a simple finite-dimensional $k$-algebra, so the isomorphism $e \cdot k \Delta^+ \cong M_t(k')$ follows from Wedderburn’s theorem. The rest is a simple calculation.

We will use this correspondence very often, so will immediately set up notation which we will use for the rest of this paper.
Notation 1.2. If an ideal $I \triangleleft kG$ contains a minimal prime ideal, then it contains a unique minimal prime ideal, say $M$. Then, under the correspondence of Lemma 1.1(ii), we obtain a unique $G$-orbit $X$ of centrally primitive idempotents of $k\Delta^+$ corresponding to $M$.

Throughout this paper, we will write

$$cpi^{k\Delta^+}(I) \quad (\text{or } cpi^{k\Delta^+}(M))$$

for this set $X$. Given a centrally primitive idempotent $e \in cpi^{k\Delta^+}(I)$, we will write $f = e|G$ to mean

$$f = \sum_{g \in C_G(e) \backslash G} e^g,$$

where $C_G(e) \backslash G$ denotes the (finite) set of right cosets of $C_G(e)$ in $G$. In other words, if we write $e = e_1$ and $X = \{e_1, \ldots, e_r\}$, then $f = e|G$ means $f = e_1 + \cdots + e_r$.

In this context, $(\cdot)$ will always mean the quotient by $JkG$ unless otherwise stated. Thus,

- $\overline{M} = (1 - f)kG$,
- $f \cdot kG = kG/\overline{M} \cong kG/M$,
- $f \cdot I = I/\overline{M} \cong I/M$,

Defin**e** 1.3. Let $P$ be a prime ideal of the ring $R$. We say that $P$ is controlled by the subring $S$ if $(P \cap S)R = P$. Following Roseblade [10, 1.1], if $R = kG$ and $S = kH$ for some closed normal subgroup $H$ of $G$, we say $P$ is controlled by $H$.

Defin**e** 1.4. For any ideal $I$ of $kG$, define also

$$I^\dagger = \{x \in G \mid x - 1 \in I\}.$$ 

This is the kernel of the natural group homomorphism $G \to (kG/I)^\times$, and so is a normal subgroup of $G$. If $I^\dagger = 1$, we say that $I$ is a faithful ideal; if $I^\dagger$ is finite, we say that $I$ is almost faithful.

In future work, we will use the techniques in this paper to show that, if $G$ is a nilpotent-by-finite, orbitally sound [12, Definition 1.4] compact $p$-adic analytic group, $k$ is a finite field of characteristic $p$, and $P$ is a prime ideal of $kG$ with $P^\dagger = 1$, then $P$ is controlled by the subgroup $\Delta(G)$.

The next two lemmas are technical results about controller subgroups: see the remarks at the start of section 3 for the big picture.

**Lemma 1.5.** Let $P$ be an ideal of $kG$ containing a prime ideal, and write $e = cpi^{k\Delta^+}(P)$, $f = e|G$ as in Notation 1.2. Let $H$ be any closed subgroup of $G$ containing $\Delta^+$. Then the following are equivalent:

---

7
\[ (P \cap kH)kG = P, \]
\[ (P \cap kH)kG = \mathcal{P}, \]
\[ (f \cdot \mathcal{P} \cap f \cdot kH) f \cdot kG = f \cdot \mathcal{P}. \]

**Proof.** Firstly, \( JkG \subseteq P \) by Lemma 1.1(i), and so by the modular law we have

\[ (P \cap kH) + JkG = P \cap (kH + JkG) \]

from which we can deduce

\[ \overline{P \cap kH} = \overline{\mathcal{P} \cap kH}, \]

and so

\[ (P \cap kH)kG = (\mathcal{P} \cap kH)kG. \]

Conversely, the preimage in \( kG \) of \( (P \cap kH)kG \) is \( (P \cap kH)kG + JkG \), but this is just \( (P \cap kH)kG \) as \( J \subseteq P \cap kH \).

Secondly, \((1 - f)kG \subseteq \mathcal{P}\), and so just as above we may deduce by the modular law

\[ f \cdot ((P \cap kH)kG) = (f \cdot \mathcal{P} \cap f \cdot kH) f \cdot kG. \]

Similarly, \(1 - f \in \overline{P \cap kH} \), so the preimage in \( kG \) of \((f \cdot \mathcal{P} \cap f \cdot kH) f \cdot kG \) is

\[ (P \cap kH)kG. \]

In order to retrieve information from Lemma 1.1(iii), we need a matrix control lemma:

**Lemma 1.6.** Let \( R \) be a ring, \( I \) an ideal of \( R \), and \( S \) a subring of \( R \). Let \( t \) be a positive integer. Then the following are equivalent:

(i) \( (I \cap S)R = I \)

(ii) \( (M_t(I) \cap M_t(S))M_t(R) = M_t(I) \)

**Proof.**

\[(i) \Rightarrow (ii)\]

Identify \( R, S \) and \( I \) with their images under the diagonal embedding \( R \hookrightarrow M_t(R) \). It is clear that

\[ I \cdot M_t(R) \subseteq M_t(I), \]

and conversely if \( a_{kl} \in I \) for all \( 1 \leq k, l \leq t \) then

\[ (a_{ij})_{i,j} = \sum_{k,l} a_{kl}E_{kl} \]
where \( E_{kl} \in M_t(R) \) is the elementary matrix with \((i,j)\)-entry \( \delta_{ik}\delta_{jl} \). So we see that \( I \cdot M_t(R) = M_t(I) \). But clearly

\[
M_t(I) = I \cdot M_t(R) = (I \cap S) R \cdot M_t(R) \\
= (I \cap S) M_t(R) \\
\subseteq (M_t(I) \cap M_t(S)) M_t(R) \\
\subseteq M_t(I),
\]

and so these are all equal.

\[\text{(ii) } \Rightarrow \text{(i)} \quad \text{Intersect both sides of the equation } (M_t(I) \cap M_t(S)) M_t(R) = M_t(I) \]

with the diagonal copy of \( R \) inside \( M_t(R) \).

Finally, we recall some basic properties of Morita equivalence:

**Lemma 1.7.** If \( R \) and \( S \) are Morita equivalent rings, then there is an order-preserving one-to-one correspondence between the ideals of \( R \) and the ideals of \( S \), and this correspondence preserves primality. \( R \) is Morita equivalent to \( M_t(R) \) for any positive integer \( t \).

**Proof.** This is [7, 3.5.5, 3.5.9].
2 The untwisting theorem

Definition 2.1. [4, Introduction] Let $G$ be a profinite group and $k$ a commutative pseudocompact ring. Then the completed group ring $kG$ is defined to be

$$kG = \lim_{\longrightarrow} k[G/N],$$

where the inverse limit ranges over all open normal subgroups $N$ of $G$, and $k[G/N]$ denotes the ordinary group algebra of the (finite) group $G/N$ over $k$.

Remark. When it helps to reduce ambiguity, we will write $kG$ as $k[[G]]$.

Recall from [7, 1.5.2] that, for any finite group $F$, there is a natural embedding of groups $i_F : F \to (kF)^{\times}$. By taking the inverse limit of the maps $\{i_{G/N}\}$, we get a continuous embedding $i : G \to (kG)^{\times}$.

Lemma 2.2 (Universal property of completed group rings). Let $G$ be a profinite group and $k$ a commutative pseudocompact ring. Then the completed group ring $kG$ satisfies the following universal property: given any pseudocompact $k$-algebra $R$ and any continuous group homomorphism $f : G \to R^{\times}$, there is a unique homomorphism $f^* : kG \to R$ of pseudocompact $k$-algebras satisfying $f^* \circ i = f$. (Here, $(kG)^{\times}$ and $R^{\times}$ are naturally viewed as subsets of $kG$ and $R$ respectively.)

Proof. Let $f : G \to R^{\times}$ be a continuous group homomorphism, and let $I$ be an open ideal of $R$ which is a neighbourhood of zero. Then $(I + 1) \cap R^{\times}$ must be open in $R^{\times}$, and so its preimage $I^1 := f^{-1}((I + 1) \cap R)$ must be open in $G$. Thus the map $f$ descends to a homomorphism of (abstract) groups $f_1 : G/I^1 \to R^{\times}/(I + 1) \cap R^{\times} \to (R/I)^{\times}$, and $G/I^1$ is finite.

Now, by the universal property for (ordinary) group rings [7, 1.5.2], we get a ring homomorphism $k[G/I^1] \to R/I$ extending $f_1$, and hence a ring homomorphism $kG \to k[G/I^1] \to R/I$ by definition. But as $R$ is the inverse limit of these $R/I$, we get a continuous ring homomorphism $kG \to R$ extending $f$.

Definition 2.3. [4, §2] Let $k$ be a commutative pseudocompact ring and $R$ a pseudocompact $k$-algebra. Let $A$ be a right and $B$ a left pseudocompact $R$-module: then the completed tensor product $A \hat{\otimes}_R B$ is a $k$-module defined by

$$A \hat{\otimes}_R B = \lim_{U,V} \left( A/U \otimes_R B/V \right),$$

where $U$ and $V$ range over the open submodules of $A$ and $B$ respectively.

Definition 2.4 (Universal property of completed tensor product). [4, §2] Let $R$ be a pseudocompact $k$-algebra, and let $A$ be a right and $B$ a left pseudocompact $R$-module. Then the completed tensor product

$$A \hat{\otimes}_R B$$
is a $k$-module satisfying the following universal property: there is a unique $R$-bihomomorphism 

$$A \times B \rightarrow A \hat{\otimes}_R B$$

through which any given $R$-bihomomorphism $A \times B \rightarrow C$ into a pseudocompact $k$-module $C$ factors uniquely. (An $R$-bihomomorphism $\theta : A \times B \rightarrow C$ is a continuous $k$-module homomorphism satisfying $\theta(ar,b) = \theta(a,rb)$ for all $a \in A, b \in B, r \in R$.)

If $R = k$, and $A$ and $B$ are $k$-algebras, then their completed tensor product is also a $k$-algebra.

**Theorem 2.5** (untwisting). Let $G$ be a compact $p$-adic analytic group, $k$ a commutative pseudocompact ring, and $kG$ the associated completed group ring. Suppose $H$ is a closed normal subgroup of $G$, and $I$ is an ideal of $kH$ such that $I \cdot kG = kG \cdot I$. Write $(\overline{\cdot}) : kG \rightarrow kG/IkG$, so that $k\overline{H} = kH/I$. Suppose also that we have a continuous group homomorphism $\delta : G \rightarrow k\overline{H}$ satisfying

1. $\delta(g) = \overline{g}$ for all $g \in H$,
2. $\delta(g)^{-1}\overline{g}$ centralises $k\overline{H}$ for all $g \in G$.

Then there exists an isomorphism of pseudocompact $k$-algebras

$$\Psi : k\overline{G} \rightarrow k\overline{H} \hat{\otimes}_k k[[G/H]],$$

where $\hat{\otimes}$ denotes the completed tensor product.

**Proof.** Firstly, the function $G \rightarrow (k\overline{H} \hat{\otimes}_k k[[G/H]])^\times$ given by

$$g \mapsto \delta(g) \otimes gH$$

is clearly a continuous group homomorphism, and so the universal property of completed group rings allows us to extend this function uniquely to a continuous ring homomorphism

$$\Psi' : kG \rightarrow k\overline{H} \hat{\otimes}_k k[[G/H]].$$

In the same way, we may extend $\delta$ uniquely to a map $\delta : kG \rightarrow k\overline{H}$, and by assumption (i), $\delta|_{kH}$ is just the natural quotient map $kH \rightarrow k\overline{H}$. Hence $\ker \delta$ must contain the two-sided ideal $IkG$, so that $\Psi'$ descends to a continuous ring homomorphism

$$\Psi : k\overline{G} \rightarrow k\overline{H} \hat{\otimes}_k k[[G/H]].$$

We claim that this is the desired isomorphism. To show that $\Psi$ is an isomorphism, we will construct a continuous ring homomorphism

$$\Phi : k\overline{H} \hat{\otimes}_k k[[G/H]] \rightarrow k\overline{G}$$
and show that \( \Phi \) and \( \Psi \) are mutually inverse.

Consider the continuous function \( \varepsilon : G \to kG^\times \) given by
\[
\varepsilon(g) = \delta(g)^{-1}g.
\]
\( \varepsilon \) is a group homomorphism: indeed, for all \( g, h \in G \), we have
\[
\varepsilon(g)\varepsilon(h) = \delta(g)^{-1}g \delta(h)^{-1}h = \delta(h)^{-1}g \delta(g)^{-1}h \quad \text{by assumption (ii)}
\]
\[
\delta(gh)^{-1}gh = \varepsilon(gh).
\]

It is clear that, by assumption (i), \( \ker \varepsilon \) contains \( H \), and so descends to a continuous group homomorphism \( \varepsilon : G/H \to kG^\times \); and so again by the universal property we get a continuous ring homomorphism \( \varepsilon : k[[G/H]] \to kG \). We also clearly have a continuous inclusion \( kH \to kG \).

These functions, and the universal property of Definition 2.4 allow us to define the desired map \( \Phi : kH \otimes k[[G/H]] \to kG \) by
\[
\Phi(x \otimes y) = x\varepsilon(y).
\]

It now remains only to check that \( \Phi \) and \( \Psi \) are mutually inverse. Indeed, for all \( g \in G \) and \( x \in kH \),
\[
\Phi(\Psi(\delta(g) \otimes gH)) = \Phi(\delta(g) \otimes H)\Phi(1 \otimes gH) = (\delta(g))\varepsilon(g) = \overline{\delta(g)}^{-1}g = \varepsilon(gh).
\]

Remark. Let \( M \) be a minimal prime of \( kG \), and \( \varepsilon \in \text{cpi}^{k\Delta^+}(M) \) (as in Notation 1.2). For most of the rest of this paper, we will insist on the mild condition that \( G \) centralise \( \varepsilon \), or equivalently that \( M \cap k\Delta^+ \) remain prime as an ideal of \( k\Delta^+ \). This is mostly to keep the notation simple: we will return briefly to this issue in section 6 and show that we have not lost much generality by doing this.
Corollary 2.6. Let $G$ be a compact $p$-adic analytic group, $k$ a finite field of characteristic $p$, and $M$ a minimal prime of $kG$. In Notation 1.2, choose $e \in \text{cpi}^{k\Delta^+}(M)$, and assume (as in the above remark) that $G$ centralises $e$, so that $(1 - e)kG = M$ and

$$kG/M \cong k\mathcal{G}/\mathcal{M} = e \cdot k\mathcal{G}.$$ 

Suppose we are given a continuous group homomorphism

$$\delta : G \to (e \cdot k\Delta^+)\times,$$

satisfying

(i) $\delta(g) = e \cdot \mathcal{G}$ for all $g \in \Delta^+$,

(ii) $\delta(g)^{-1}\mathcal{G}$ centralises $e \cdot k\Delta^+$ for all $g \in G$.

Then there exists an isomorphism

$$\Psi : e \cdot k\mathcal{G} \to e \cdot k\Delta^+ \otimes_k k[[G/\Delta^+]],$$

and hence also an isomorphism

$$\psi : e \cdot k\mathcal{G} \to M_t(k'[G/\Delta^+])$$

for some positive integer $t$ and some finite field extension $k'/k$.

Proof. In Theorem 2.5, take $H = \Delta^+$, and take $I$ to be the ideal of $k\Delta^+$ generated by $J(k\Delta^+)$ and $1 - a$, where $a \in k\Delta^+$ is any element whose image in $k\Delta^+$ is $e$. This gives the isomorphism

$$\Psi : e \cdot k\mathcal{G} \to e \cdot k\Delta^+ \otimes_k k[[G/\Delta^+]];$$

but now, as $e \cdot k\Delta^+$ is finite-dimensional as a vector space over $k$, [4, Lemma 2.1(ii)] implies that the right hand side is equal to the ordinary tensor product

$$e \cdot k\Delta^+ \otimes_k k[[G/\Delta^+]].$$

Now the isomorphism $\psi$ is given by composing $\Psi$ with the isomorphism of Lemma 1.1(iii). $\square$

Remark. Note that, when $G \cong N \times \Delta^+$ as in [3, 10.1], $\delta$ is simply taken to be the composite of the natural map $N \times \Delta^+ \to \Delta^+$ given by projection onto the second factor and the inclusion map $\Delta^+ \hookrightarrow (e \cdot k\Delta^+)\times$. 

13
3 Almost faithful ideals

Throughout this section:

- $G$ is a compact $p$-adic analytic group, and $k$ is a finite field of characteristic $p$.
- $M$ is a minimal prime ideal of $kG$ and $e \in \text{cpi} k^{\Delta^+} M$, so that Notation 1.2 applies.
- Assume further that $G$ centralises $e$, and that we have an untwisting map
  \[ \delta : G \to (e \cdot kG)^\times \]
  satisfying the hypotheses of Corollary 2.6 and write
  \[ \psi : e \cdot kG \to M \otimes_{k[[G/\Delta^+]]} k'[[G/\Delta^+]] \]
  for the corresponding isomorphism given by Corollary 2.6.
- Write $q : kG \to e \cdot kG$ for the natural quotient map.

(We leave it until section 4 to find such a $\delta$ for a certain large class of groups $G$.)

In this setting, we have the following one-to-one correspondences of ideals:

\[
\begin{array}{c}
\{ \text{ideals of } kG \text{ which contain } M \} \\
\downarrow q \\
\{ \text{ideals of } e \cdot kG \} \\
\downarrow \psi \\
\begin{array}{c}
\{ \text{ideals of } M_t(k'[[G/\Delta^+]]) \} \\
\text{Morita equiv.} \\
\{ \text{ideals of } k'[[G/\Delta^+]] \}
\end{array}
\end{array}
\]

Lemmas 1.5 and 1.6 may now be interpreted as demonstrating that the first and third correspondences in this diagram preserve some notion of control (as defined in Definition 1.3). The middle correspondence trivially preserves control, as $\psi$ is an isomorphism. We remark also that all three correspondences preserve primality, the third by Lemma 1.7.

In this section, we show that some appropriate notion of almost-faithfulness (see Definition 1.4) is also preserved by these correspondences. That is, let $P$ be any ideal of $kG$ containing $M$. Then we have

\[ \psi \circ q(P) = M_t(p), \]

where $p$ is some ideal of $k'[[G/\Delta^+]].$ Recall the definition of $(-)^\dagger$ from Definition 1.4: we intend to show that the groups $P^\dagger$ (a subgroup of $G$) and $p^\dagger$ (a subgroup of $G/\Delta^+$) are closely related.

We will abuse notation to identify the two rings

\[ e \cdot k^{\Delta^+} \otimes_k k[[G/\Delta^+]] = e \cdot k^{\Delta^+} \otimes_{k'} k'[[G/\Delta^+]] \]
in the obvious way. Then, laying out the structure more explicitly, we have

\[ \Psi(e \cdot P) = e \cdot \frac{k\Delta^+ \otimes p}{k'} \]

in the notation of Corollary 2.6.

Suppose that \( g\Delta^+ \in p^+ \) for some \( g \in G \), i.e. \( (g - 1)\Delta^+ \in p \). Then

\[ (1 \otimes g\Delta^+) - (1 \otimes \Delta^+) \in \Psi(e \cdot P), \]

so

\[ \Phi(1 \otimes g\Delta^+) - \Phi(1 \otimes \Delta^+) = \delta(g)^{-1} - e \in e \cdot P. \]

This motivates the following definition:

**Definition 3.1.** Write

\[ P^\dagger_\delta = \{ g \in G \mid \delta(g)^{-1} - e \in e \cdot P \}, \]

so that \( P^\dagger_\delta \) is the kernel of the composite map

\[ G \xrightarrow{\varepsilon} (e \cdot kG)^\times \xrightarrow{\sim} (kG/M)^\times \xrightarrow{\sim} (kG/P)^\times, \]

where \( \varepsilon : G \rightarrow (e \cdot kG)^\times \) is defined by \( \varepsilon(g) = \delta(g)^{-1} - e \). (As we saw in the proof of Theorem 2.5, \( \varepsilon \) is a continuous group homomorphism.) Compare this with Definition 1.4.

Now, since \( \varepsilon(g) = 1 \) for all \( g \in \Delta^+ \), we have \( \Delta^+ \leq P^\dagger_\delta \) for any ideal \( P \). We say that \( P \) is \( \delta \)-faithful if \( P^\dagger_\delta = \Delta^+ \) (and \( P \) is \( \delta \)-unfaithful if \( P^\dagger_\delta \) is infinite).

**Lemma 3.2.** The following are equivalent:

(i) \( P \) is almost faithful (as an ideal of \( kG \)).

(ii) \( P \) is \( \delta \)-faithful.

(iii) \( p \) is faithful (as an ideal of \( k'[G/\Delta^+] \)).

**Proof.**

(ii) \( \Leftrightarrow \) (iii) By the above calculation, we see that \( P \) is defined to be a \( \delta \)-faithful ideal of \( kG \) precisely when \( p \) is a faithful ideal of \( k'[G/\Delta^+] \).

(i) \( \Leftrightarrow \) (ii) Let \( m = |\text{im}(\delta)|. \) Note that \( m < \infty \) as \( k \) is assumed to be a finite field. Then \( \delta(g^m) = 1 \) for all \( g \in G \), so
so writing \((P_i)^m := \langle g^m | g \in P_i \rangle\), and likewise \((P_i^\dagger)^m\), we see that these two subgroups are equal.

Now, suppose \(P\) is almost faithful, and so in particular \(P^\dagger\) is torsion; then the subgroup \((P_i^\dagger)^m = (P_\delta^\dagger)^m\) is also torsion, and since \(g^m\) is torsion for any \(g \in P_\delta^\dagger\), we have that \(g\) must also be torsion. So \(P_\delta^\dagger\) is a torsion subgroup of \(G\). Hence it must be finite; indeed, given any open normal uniform subgroup \(U\) of \(G\), the kernel of the composite map \(P_\delta^\dagger \hookrightarrow G \to G/U\) is a subgroup of \(U \cap P_\delta^\dagger\), which is trivial as \(U\) is torsion-free \cite[4.5]{5}. So \(P_\delta^\dagger\) embeds into the finite group \(G/U\), and as \(P_\delta^\dagger\) is also normal in \(G\) by Definition \ref{def:normal}, it is a finite orbital subgroup of \(G\) and hence must be a subgroup of \(\Delta^+\), i.e. \(P\) is \(\delta\)-faithful. The converse is similar.

In summary:

**Corollary 3.3.** Assume the hypotheses of Corollary \ref{cor:almost-faithful}. Let \(P\) be an ideal of \(kG\) containing \(M\), and denote by \(q : kG \to kG/M\) the natural quotient map. Write \(\psi \circ q(P) = M_{i}(p)\), where \(p\) is an ideal of \(k'[\![G/\Delta^+]\!]\). Then \(p\) is faithful if and only if \(P\) is almost faithful; and \(p\) is prime if and only if \(P\) is prime.
4 Untwisting when $G$ is finite-by-(pro-$p$)

In this section, we introduce a group $A_H$ for each closed subgroup $H$ of $G$. By studying the structure of the group $A_G$ in the case when $G/\Delta^+$ is pro-$p$, we will find an untwisting map $\delta : G \to (e \cdot k\Delta^+)^\times$ satisfying the conditions of Corollary 2.6.

Let $G$ be a compact $p$-adic analytic group, $k$ a finite field of characteristic $p$, $M$ a minimal prime of $kG$, and $e \in \mathfrak{cpl}(\Delta^+)(M)$, which we continue to suppose is centralised by $G$. Then $e \cdot k\Delta^+ \cong M_i(k')$, and in particular its automorphisms are all inner by the Skolem-Noether theorem [11, Tag 074P].

Note that both $G$ and $(e \cdot k\Delta^+)^\times$ act on the ring $e \cdot k\Delta^+$ by conjugation, and so we get group homomorphisms $G \to \text{Inn}(e \cdot k\Delta^+)$ and $(e \cdot k\Delta^+)^\times \to \text{Inn}(e \cdot k\Delta^+)$.  

**Definition 4.1.** For any closed subgroup $H \leq G$, define $A_H$ to be the fibre product of $H$ and $(e \cdot k\Delta^+)^\times$ over $\text{Inn}(e \cdot k\Delta^+)$ with respect to the above maps,

$$A_H = (e \cdot k\Delta^+)^\times \times \text{Inn}(e \cdot k\Delta^+) \times H,$$

a subgroup of $(e \cdot k\Delta^+)^\times \times H$. Write the projection map onto the second factor as $\pi_H : A_H \to H$.

As $e \cdot k\Delta^+ \cong M_i(k')$, we have $(e \cdot k\Delta^+)^\times \cong GL_i(k')$. The centre of $(e \cdot k\Delta^+)^\times$ is therefore isomorphic to $Z(GL_i(k'))$, which we will identify with $k'^\times$, and the inner automorphism group $\text{Inn}(e \cdot k\Delta^+)$ is isomorphic to $PGL_i(k')$. In particular, $A_H$ is an extension of $H$ by $k'^\times$. Indeed, the following diagram commutes and has exact rows:

$$\begin{array}{cccccc}
1 & \longrightarrow & k'^\times & \longrightarrow & A_H & \longrightarrow & H & \longrightarrow & 1 \\
\downarrow & & \downarrow & & \uparrow & & \downarrow & & \downarrow \\
1 & \longrightarrow & k'^\times & \longrightarrow & (e \cdot k\Delta^+)^\times & \longrightarrow & \text{Inn}(e \cdot k\Delta^+) & \longrightarrow & 1.
\end{array}$$

The inclusion $i : k'^\times \to A_H$ is given by $i(x) = (x, 1)$. (The image of $i$ is just $A_{\{1\}}$.)

We will now examine the subgroup structure of $A_G$.

**Lemma 4.2.** If $N$ is a closed normal subgroup of $G$, then $A_N \triangleleft A_G$, and $A_G/A_N \cong G/N$.

**Proof.** Firstly, clearly $A_N$ is naturally a subgroup of $A_G$, and the following diagram commutes and has exact rows:

$$\begin{array}{cccccc}
1 & \longrightarrow & k'^\times & \longrightarrow & A_N & \longrightarrow & N & \longrightarrow & 1 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
1 & \longrightarrow & k'^\times & \longrightarrow & A_G & \longrightarrow & G & \longrightarrow & 1.
\end{array}$$
Let \((r, n) \in A_N\) and \((s, g) \in A_G\). For any \(x \in (e \cdot k \Delta^+)\), we have \(x^r = x^n\) and \(x^s = x^g\), so we get \(x^{s^{-1}rs} = x^{g^{-1}ng}\). As \(g^{-1}ng \in N\), we have

\[(s, g)^{-1}(r, n)(s, g) = (s^{-1}rs, g^{-1}ng) \in A_N,\]

and so \(A_N \triangleleft A_G\).

Hence we may take cokernels of the vertical maps, completing the above diagram to the following commutative diagram, whose columns and first two rows are exact:

\[
\begin{array}{ccccccccc}
1 & & 1 & & 1 & & 1 & & 1 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
1 & \rightarrow & k' \times & \rightarrow & A_N & \rightarrow & N & \rightarrow & 1 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
1 & \rightarrow & k' \times & \rightarrow & A_G & \rightarrow & G & \rightarrow & 1 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
1 & 1 & \rightarrow & A_G/A_N & \rightarrow & G/N & \rightarrow & 1 & \\
\end{array}
\]

By the Nine Lemma, the third row is now also exact. \(\Box\)

Consider the natural map \(\Delta^+ \rightarrow (e \cdot k \Delta^+)\times\) given by \(g \mapsto e \cdot \overline{g}\). There is a “diagonal” inclusion map \(d : \Delta^+ \rightarrow A_G\) given by \(g \mapsto (e \cdot \overline{g}, g)\), and the image \(d(\Delta^+)\) is normal in \(A_G\); indeed, suppose we are given \((x, h) \in A_G\). Then

\[
d(g)^{(x,h)} = (x, h)^{-1}(e \cdot \overline{g}, g)(x, h) \\
= ((e \cdot \overline{g})^x, g^h) \\
= ((e \cdot \overline{g})^h, g^h) \\
= d(g^h).
\]

**Remark.** The map \(d\), considered as a map from \(\Delta^+\) to \(A_{\Delta^+}\), splits the map \(\pi_{\Delta^+}\).

Hence there are copies of \(k'\times\) and \(\Delta^+\) in \(A_{\Delta^+}\), and they commute: given \(x \in k'\times\), \(g \in \Delta^+\), we have

\[
i(x)d(g) = (x, 1)(e \cdot \overline{g}, g) = (e \cdot \overline{g}, g)(x, 1) = d(g)i(x)
\]

as \(x\) commutes with \(e \cdot \overline{g}\) inside \(e \cdot k \Delta^+\). In other words,

\[
A_{\Delta^+} = i(k'\times)d(\Delta^+) \cong k'\times \times \Delta^+.
\]
Lemma 4.3. Let $G$ be a compact $p$-adic analytic group. Suppose that we have an injective group homomorphism $\sigma : G \to A_G$ splitting $\pi_G$ such that, for all $g \in \Delta^+$, we have $\sigma(g) = (e \cdot \mathfrak{f}, g)$. Then we can find a $\delta$ satisfying the conditions of Corollary 2.6.

Proof. Define $\delta$ to be the composite of $\sigma : G \to A_G$ with the projection $A_G \to (e \cdot k\Delta^+)\times$.

We assume for the remainder of this section that $G/\Delta^+$ is pro-$p$, and find a map $\sigma$ satisfying Lemma 4.3 for this case.

Write $P = G/\Delta^+$. Note that $A_G/d(\Delta^+)$ is an extension of $A_G/A_{\Delta^+}$ (which is isomorphic to $P$, a pro-$p$ group, by Lemma 1.2) by $A_{\Delta^+}/d(\Delta^+)$ (which is isomorphic to $k'\times$, a $p'$-group, by the discussion above). Hence, as $k$ is still assumed to be finite, we may apply Sylow’s theorems [5, §1, exercise 11] to find a Sylow pro-$p$ subgroup $L/d(\Delta^+)$ of $A_G/d(\Delta^+)$ which is isomorphic to $P$.

This information is summarised in the following diagram.

\[
\begin{array}{c}
\begin{array}{c}
A_G \\
\downarrow p \\
L \\
\downarrow \Delta^+ \\
A_{\Delta^+} \\
\downarrow i(k'\times) \\
k'\times \\
\downarrow d(\Delta^+) \\
\downarrow \Delta^+
\end{array}
\end{array}
\]

Lemma 4.4. Suppose $G/\Delta^+$ is pro-$p$. Then there is a map $\sigma$ splitting the surjection $\pi_G : A_G \to G$ satisfying the hypotheses of Lemma 4.3.

Proof. Consider $\pi_G|_L : L \to G$. Now, $\ker(\pi_G) = i(k'\times)$, so

$$\ker(\pi_G|_L) = i(k'\times) \cap L = i(k'\times) \cap A_{\Delta^+} \cap L = i(k'\times) \cap (A_{\Delta^+} \cap L) = i(k'\times) \cap d(\Delta^+) = 1,$$

so $\pi_G|_L$ is injective. Also,

$$i(k'\times) \cdot L = A_{\Delta^+} \cdot L = A_G,$$
\[ G = \pi_G(A_G) = \pi_G(i(k'^\times) \cdot L) = \pi_G(i(k'^\times)) \cdot \pi_G(L) = \pi_G(L) \]

as \( \pi_G(i(x)) = \pi_G((x, 1)) = 1 \) for \( x \in k'^\times \), and hence \( \pi_G|_L \) is surjective. So \( \pi_G|_L \) is in fact an isomorphism \( L \to G \).

Define \( \sigma : G \to L \to A_G \) (i.e. \( (\pi_G|_L)^{-1} \) followed by inclusion). By construction, this \( \sigma \) splits \( \pi_G \). Also, as \( \pi_G(\sigma(g)) = \pi_G(d(g)) = g \) for all \( g \in \Delta^+ \), we have that \( \sigma(g)d(g)^{-1} \in \ker \pi_G \cap L = 1 \), and so \( \sigma(g) = d(g) = (e \cdot y, g) \) for \( g \in \Delta^+ \) as required.

Now we may define \( \delta : G \to (e \cdot k\Delta^+)^\times \) as in the proof of Lemma 4.3, allowing us to deduce the following theorem, in which we continue to write \( q : kG \to e \cdot kG \) for the natural quotient map:

**Theorem 4.5.** Let \( G \) be a compact \( p \)-adic analytic group with \( G/\Delta^+ \) pro-\( p \), and let \( k \) be a finite field. Write \( N = G/\Delta^+ \). Let \( M \) be a minimal prime of \( kG \), and \( e \in \text{cpi}^\Delta(M) \), and suppose that \( e \) is centralised by \( G \). Then we can find a \( \delta : G \to (e \cdot k\Delta^+)^\times \) satisfying the conditions of Corollary 2.6. In particular:

(i) There exists an isomorphism

\[
\Psi : e \cdot kG \to e \cdot k\Delta^+ \otimes_k kN.
\]

(ii) There exist a finite field extension \( k'/k \) and a positive integer \( t \), and an isomorphism

\[
\psi : e \cdot kG \to M_t(k'N).
\]

Furthermore, let \( A \) be an ideal of \( kG \) with \( M \subseteq A \), so that \( \psi \circ q(A) = M_t(a) \) for some ideal \( a \) of \( k'N \). Then:

(iii) \( A \) is prime if and only if \( a \) is prime. Also, \( A \) is almost \((G-)\)-faithful if and only if \( a \) is \((N-)\)-faithful.

**Proof.**

(i) The map \( \delta \) as defined by Lemmas 4.3 and 4.4 satisfies the conditions of Corollary 2.6 which gives the isomorphism \( \Psi : e \cdot kG \to e \cdot k\Delta^+ \otimes_k [[G/\Delta^+]]. \)

(ii) As in Corollary 2.6, we may identify \( e \cdot k\Delta^+ \otimes_k [[G/\Delta^+]] \) with \( M_t(k'[G/\Delta^+]] \) by appealing to Lemma 1.1(iii).

(iii) This is just Corollary 3.3. 

**Proof of Theorem A.** This is contained within the above theorem.
5 Central twists by 2-cocycles

First, some basic definitions.

**Definition 5.1.** Let $A$ be a ring and $G$ a group. Suppose we have a function of sets

$$\sigma : G \to \text{Aut}(A).$$

(We will write the image of $a \in A$ under the automorphism $\sigma(g)$ as $a^{\sigma(g)}$.) Let $\alpha : G \times G \to A$ be a function of sets.

If, for all $x, y, z \in G$, we have

$$\alpha(xy, z)\alpha(x, y)^{\sigma(z)} = \alpha(x, yz)\alpha(y, z), \quad (5.1)$$

then $\alpha$ is a 2-cocycle (with respect to $\sigma$). We will write the set of such functions $\alpha$ as $Z^2_\sigma(G, A)$.

Let $G$ be a finite group, $R$ a ring, and $S = R \ast G$ a fixed crossed product. Recall [9, §1] that this means that:

- $S$ is a free $R$-module on a generating set $\overline{G} \subseteq S$, where $|\overline{G}| = |G|$, and we shall write its elements as $\overline{g}$ for $g \in G$;
- multiplication in $S$ is given by

  $$\overline{rg} = \overline{g}^{\sigma(g)} \quad \text{for all } r \in R, g \in G,$$

  $$\overline{gh} = \overline{g} \overline{h}^{\tau(g, h)} \quad \text{for all } g, h \in G,$$

where

$$\sigma : G \to \text{Aut}(R), \quad \text{the action},$$

$$\tau : G \times G \to R^\times, \quad \text{the twisting},$$

are two functions of sets satisfying

$$\sigma(x)\sigma(y) = \sigma(xy)\eta(x, y) \quad (5.2)$$

$$\tau(xy, z)\tau(x, y)^{\sigma(z)} = \tau(x, yz)\tau(y, z), \quad (5.3)$$

where $\eta(x, y)$ is the automorphism of $R$ given by conjugation by $\tau(x, y)$.

Equation (5.3) says that $\tau$ is a 2-cocycle for $\sigma$ with values in $R^\times$.

**Notation 5.2.** We will often need to write this structure explicitly as

$$S = R \ast \langle \sigma, \tau \rangle \ G.$$
Suppose we wish to define some new crossed product, keeping the action the same but changing the twisting, say

\[ S' = R \ast_{(\sigma, \tau')} G. \]

For the rest of this section, until stated otherwise, we will write \( A = Z(R^\times). \)

**Lemma 5.3.** \( S' \) is a ring if and only if there exists \( \alpha \in Z^2_\sigma(G, A) \) satisfying \( \tau'(x, y) = \tau(x, y)\alpha(x, y) \) for all \( x, y \in G. \)

**Proof.** Equation \((5.2)\), applied to both \( S \) and \( S' \), gives

\[
\sigma(x)\sigma(y) = \sigma(xy)\eta(x, y) \quad \text{and} \quad \sigma(x)\sigma(y) = \sigma(xy)\eta'(x, y)
\]

for all \( x, y \in G, \) where \( \eta(x, y) \) and \( \eta'(x, y) \) are the automorphisms induced by conjugation by \( \tau(x, y) \) and \( \tau'(x, y) \) respectively. This implies that \( \eta = \eta' \). In other words, writing \( \alpha = \tau^{-1}\tau' \) pointwise, we see that conjugation by \( \alpha(x, y) \) induces the trivial automorphism on \( R, \) and so

\[
\alpha : G \times G \to Z(R^\times) = A,
\]

and it follows from equation \((5.3)\) that, in order for \( S' \) to be a ring, \( \alpha \) must be a 2-cocycle for \( \sigma \) taking values in \( A. \) The converse is identical. \( \square \)

**Definition 5.4.** When the crossed product \( S = R \ast G = R \ast_{(\sigma, \tau)} G \) and the central 2-cocycle \( \alpha \) are fixed, write the ring \( S' \) defined above as \( S_\alpha \): we will say that \( S_\alpha \) is the central 2-cocycle twist of \( S \) by \( \alpha \) with respect to the decomposition \( S = R \ast_{(\sigma, \tau)} G, \) meaning that

\[
S_\alpha = R \ast_{(\sigma, \tau\alpha)} G.
\]

Sometimes it will not be necessary to specify all of this information in full; we may simply refer to \( S_\alpha \) as a central 2-cocycle twist of \( S, \) or similar.

Note that \( S_\alpha \) depends not only on the map \( \tau, \) but also on the choice of basis \( G \) for \( S = R \ast G. \)

**Remark.** Fix a crossed product \( S = R \ast G, \) and choose some \( \alpha \in Z^2_\sigma(G, A). \) Write the resulting crossed product decompositions as

\[
S = \bigoplus_{g \in G} Rg, \quad S_\alpha = \bigoplus_{g \in G} R\hat{g}.
\]
We say that $S$ and $S_\alpha$ differ by a diagonal change of basis if, for each $g \in G$, there is some unit $u_g \in R^\times$ such that $\hat{g} = \pi u_g$. (In particular, if $S$ and $S_\alpha$ differ by a diagonal change of basis, they are isomorphic.) By [9, exercise 1.1], $S$ and $S_\alpha$ differ by a diagonal change of basis if and only if $\alpha$ is a 2-coboundary for $\sigma$, i.e. there is some function $\varphi : G \to R^\times$ with

$$\alpha(x, y) = \varphi(xy)^{-1} \varphi(x)^{\sigma(y)} \varphi(y)$$

for all $x, y \in G$. Hence $S$ and $S_\alpha$ are non-isomorphic only if $\alpha$ has non-trivial cohomology class. But we will not develop this idea any further in this paper.

Remark. We note that similar twists have been studied by Aljadeff et al., e.g. in [1].

Central 2-cocycle twists will occur naturally in the theory later. For now, we see where this will be applied:

**Definition 5.5.** [9, Lemma 12.3] Let $R$ be a prime ring. An automorphism $\varphi : R \to R$ is X-inner if there exist nonzero elements $a, b, c, d \in R$ such that, for all $x \in R$,

$$axb = cx^\varphi d.$$  

(Here $x^\varphi$ denotes the image of $x$ under $\varphi$.) Write $\text{Xinn}(R)$ to denote the subgroup of $\text{Aut}(R)$ of X-inner automorphisms.

Now let $G$ be a group, and fix a crossed product

$$S = R \ast G = R \ast (\sigma, \tau).$$

Write $\text{Xinn}_S(R; G)$ for the normal subgroup of $G$ consisting of elements $g \in G$ that act by X-inner automorphisms on $R$, i.e.

$$\text{Xinn}_S(R; G) = \sigma^{-1}(\sigma(G) \cap \text{Xinn}(R)).$$

**Theorem 5.6.** Fix a crossed product $S = R \ast G$ with $R$ prime, $G$ finite. Then $\text{Xinn}_S(R; G) = \text{Xinn}_{S_\alpha}(R; G)$ for every $\alpha \in Z^2_\alpha(G, A)$. In particular, if $\text{Xinn}_S(R; G) = 1$, then $S_\alpha$ is a prime ring for every $\alpha \in Z^2_\alpha(G, A)$.

**Proof.** It is clear from the definition that $\text{Xinn}_{S_\alpha}(R; G)$ depends only on the map $\sigma$, and so $\text{Xinn}_{S_\alpha}(R; G) = \text{Xinn}_S(R; G)$ for all $\alpha$. A special case of [9, Corollary 12.6] implies that, if $\text{Xinn}_{S_\alpha}(R; G) = 1$, then $S_\alpha$ is a prime ring.

This theorem will be important in later work, but we will not return to it in this paper.

Now we turn our attention back to the problem of understanding quotients of completed group algebras.
Let $G$ be a compact $p$-adic analytic group, $M$ a minimal prime of $kG$, and $e \in \text{cpi}^k\Delta^+(M)$ centralised by $G$. In this more general case, we may not be able to find a group homomorphism

$$\delta : G \to (e \cdot \overline{k\Delta^+})^\times$$

satisfying the hypotheses of Corollary 2.6, so we may not be able to find an isomorphism

$$\psi : e \cdot \overline{kG} \to M_t(k'[\Delta^+]).$$

In this case, fix (by [4, 6]) an open normal pro-$p$ (e.g. $p$-valued) subgroup $N$ of $G/\Delta^+$, and write $H$ for the preimage of $N$ in $G$, so that by Theorem 4.5 we do get an isomorphism

$$\psi : e \cdot \overline{kH} \to M_t(k'N).$$

Now we will have to rely on the crossed product structure of $kG$. That is, writing $F = G/H$, we can find a crossed product decomposition

$$kG = kH \ast F.$$

In the following discussion, we will construct a related crossed product $k'N \ast F$ (not necessarily isomorphic to $k'[[G/\Delta^+]]$), and show that the isomorphism $\psi$ extends to an isomorphism

$$\tilde{\psi} : e \cdot \overline{kG} \to M_t(k'N \ast F).$$

Studying the structure of this crossed product $k'N \ast F$ will allow us to understand the prime ideals of $kG$. In fact, we will show that $k'N \ast F$ is a central 2-cocycle twist of $k'[[G/\Delta^+]]$.

Recall the map $\delta : H \to (e \cdot \overline{k\Delta^+})^\times$ from Theorem 4.5 and continue to write

$$\varepsilon : H \to (e \cdot \overline{kH})^\times$$

$$h \mapsto \delta(h)^{-1}\overline{h}$$

for all $h \in H$, as in the proof of Theorem 2.5.

For the remainder of this section, we fix an element $g \in G$.

Fix $M_g \in (e \cdot \overline{k\Delta^+})^\times$, an arbitrary lift of the image of $g$ under the map $G \to \text{Inn}(e \cdot \overline{k\Delta^+})$, i.e. any element such that $x^g = x^{M_g}$ for all $x \in e \cdot \overline{k\Delta^+}$, and hence $(M_g, g) \in A_G$. Define

$$\tilde{g} = M_g^{-1} \overline{g} \in (e \cdot \overline{kG})^\times$$

(5.4)

– this element will play the role of “$\varepsilon(g)$” when $g \notin H$.

Conjugation by $\tilde{g}$ is a ring automorphism $\varphi_g \in \text{Aut}(e \cdot \overline{kH})$, which induces a ring automorphism

$$\Psi \circ \varphi_g \circ \Phi =: \theta_g \in \text{Aut}(e \cdot \overline{k\Delta^+} \otimes_k kN).$$
(For ease of notation, we will revert to writing these maps on the left.)

That is:
\[
\begin{array}{ccc}
e \cdot kH & \xrightarrow{\varphi_g} & e \cdot kH \\
\Phi & \downarrow & \downarrow \\
e \cdot k\Delta^+ \otimes kN & \xrightarrow{\theta_g} & e \cdot k\Delta^+ \otimes kN
\end{array}
\]

For ease of notation, we will write these maps on the left as before.

Given \( r \in e \cdot k\Delta^+ \) and \( h \in \Delta^+ \), we wish to calculate \( \theta_g(r \otimes h\Delta^+) \) explicitly.

We begin with a trivial remark:

**Lemma 5.7.** By construction, \( \varphi_g(r) = r \), and so \( \theta_g(r \otimes 1) = r \otimes 1 \).

Next, a computational lemma:

**Lemma 5.8.** Suppose \( N \) is pro-\( p \) and \( k'_{\times} \) contains no non-trivial pro-\( p \) subgroups. Then \( \delta(h)^g = \delta(h^g) \) for all \( h \in H \).

*Proof.* Define \( \beta_g : H \to (e \cdot k\Delta^+)_{\times} \) by \( \beta_g(h) = \delta(h^g)^{-1}\delta(h^g) \). We aim to show that \( \beta_g(h) = 1 \) for all \( h \).

For any \( r \in e \cdot k\Delta^+ \), we have that
\[
\begin{align*}
\varphi((r^g)^{-1}h)^g & = \varphi((r^g)^{-1}h)^g \\
& = \delta(h)^g \\
& = \beta_g(h),
\end{align*}
\]

and so \( \beta_g(h) = r \), i.e. \( \beta_g(h) \) is in the centre of \( (e \cdot k\Delta^+)_{\times} \). So \( \beta_g \) is a map from \( H \) to \( k'_{\times} \).

Let \( h_1, h_2 \in H \). Since \( \beta_g(h_1) = \delta(h_1^g)^{-1}\delta(h_1)^g \) is central in \( (e \cdot k\Delta^+)_{\times} \), in particular it centralises \( \delta(h_2^g)^{-1} \), and so
\[
\begin{align*}
\beta_g(h_1h_2) & = \delta((h_1h_2)^g)^{-1}\delta(h_1h_2)^g \\
& = \delta(h_2^g)^{-1}\delta(h_1^g)^{-1}\delta(h_1)^g\delta(h_2)^g \\
& = \beta_g(h_1)\beta_g(h_2),
\end{align*}
\]

so \( \beta_g \) is a group homomorphism \( H \to k'_{\times} \). Furthermore, when \( h \in \Delta^+ \),
\[
\begin{align*}
\beta_g(h) & = \delta(h^g)^{-1}\delta(h)^g \\
& = (e \cdot h)^{-1}(e \cdot h)^g = 1.
\end{align*}
\]
So $\Delta^+ \leq \ker \beta_g$, and so $\beta_g$ in fact descends to a homomorphism from $N$ (a pro-$p$ group) to $k'^\times$ (containing no non-trivial pro-$p$ subgroups), and so must be trivial. \hfill \square

Continue to write $\varepsilon(h) = \delta(h)^{-1}h$ for all $h \in H$. Then, finally, we can conclude:

**Corollary 5.9.** Suppose $N$ is pro-$p$ and $k'^\times$ contains no non-trivial pro-$p$ subgroups. Then $\varepsilon(h)\tilde{g} = \varepsilon(h^g)$ for all $h \in H$.

**Proof.** We have

\[
\varepsilon(h)^\tilde{g} = \varepsilon(h)^g \\
= (\delta(h)^g)^{-1}h^g \\
= (\delta(h^g))^{-1}h^g \\
= \varepsilon(h^g),
\]

as required. \hfill \square

Now we can calculate the action of $\theta_g$ on $e \cdot k\Delta^+ \otimes kN$:

**Lemma 5.10.** Given $r \in e \cdot k\Delta^+$ and $h\Delta^+ \in N$, with $N$ pro-$p$ and $k'^\times$ containing no non-trivial pro-$p$ subgroups as above, we have

\[
\theta_g(r \otimes h\Delta^+) = r \otimes (h\Delta^+)^{g\Delta^+}.
\]

**Proof.**

\[
\theta_g(r \otimes h\Delta^+) = \Psi(\varphi_g(\Phi(r \otimes h\Delta^+))) \\
= \Psi(\varphi_g(\varepsilon(h))) \\
= \Psi(\varepsilon(h)^\tilde{g}) \\
= \Psi(\varepsilon(h^g)) \\
= \Psi(\Phi(r \otimes h^g\Delta^+)) \\
= r \otimes h^g\Delta^+ \\
= r \otimes (h\Delta^+)^{g\Delta^+}.
\]

Now finally we can prove the main theorem of this section.

Let $G$ be a compact $p$-adic analytic group and $H$ an open normal subgroup containing $\Delta^+$ with $H/\Delta^+$ a pro-$p$ group. Suppose $k$ is a finite field of characteristic $p$. Fix a minimal prime $M$ of $kH$, and $e \in \text{cpi}^{\overline{k\Delta^+}}(M)$, and suppose that $e$ is centralised by $G$.

26
As \( H \) satisfies the conditions of Theorem 4.5, there exist a finite field extension \( k'/k \) and a positive integer \( t \), and isomorphisms
\[
\Psi : e \cdot kH \rightarrow e \cdot k\Delta^+ \otimes k'N,
\]
\[
\psi : e \cdot kH \rightarrow M_t\left(k'[\![H/\Delta^+]\!]\right).
\]
(Note that, here, we have identified the two rings \( e \cdot k\Delta^+ \otimes kN \) and \( e \cdot k\Delta^+ \otimes k'N \) as in Lemma 1.1(iii).)

Fix a crossed product decomposition
\[
k'[\![G/\Delta^+]\!] = k'[\![H/\Delta^+]\!]*_{(\sigma,\tau)} (G/H).
\]

Theorem 5.11. Notation as above. Then there exists
\[
\alpha \in Z_2^2\left(G/H, Z(k'[\![H/\Delta^+]\!]^*\right)
\]
such that \( \Psi \) extends to an isomorphism
\[
\tilde{\Psi} : e \cdot kG \rightarrow e \cdot k\Delta^+ \otimes \left(k'[\![G/\Delta^+]\!]\right)_\alpha,
\]
where the 2-cocycle twist \( (k'[\![G/\Delta^+]\!]_\alpha \) is taken with respect to the crossed product decomposition (†) above, as defined in Definition 5.4.

Hence \( \psi \) also extends to an isomorphism
\[
\tilde{\psi} : e \cdot kG \rightarrow M_t\left(k'[\![G/\Delta^+]\!]\right)_\alpha.
\]

Proof. We know that \( e \cdot k\Delta^+ \cong M_t(k') \) for some \( t \) and \( k' \) by Lemma 1.1, and so \( e \cdot k\Delta^+ \) contains a set \( \{e_{ij}\} \) of \( t^2 \) matrix units. Set
\[
Z_H := Z_{e \cdot kH}\left(\{e_{ij}\}\right) \subseteq e \cdot kH,
\]
the centraliser of all of these matrix units, and likewise \( Z_G \subseteq e \cdot kG \) and \( Z_{\Delta^+} \subseteq e \cdot k\Delta^+ \). Then the statement and proof of [8, 6.1.5] show that
\[
e \cdot kH \cong e \cdot k\Delta^+ \otimes Z_H
\]
and
\[
e \cdot kG \cong e \cdot k\Delta^+ \otimes Z_G.
\]
Since \( e \cdot k\Delta^+ \cong M_t(k') \), it is clear that \( Z_{\Delta^+} \cong k' \), the diagonal copy of \( k' \) inside \( M_t(k') \). Using the isomorphism \( \Psi \) of Theorem 4.5, we can also understand the structure of \( Z_H \):
\[
\Psi(Z_H) = Z_{\Delta^+} \otimes k[[H/\Delta^+]] \cong k'[[[H/\Delta^+]],
\]

27
so \( \Psi \) restricts to an explicit isomorphism \( Z_H \to k'[\![H/\Delta^+]\!] \). Now we would like to understand the structure of \( Z_G \).

As \( F := G/H \) is finite, we may write \( \{x_1, \ldots, x_n\} \) for a set of representatives in \( G \) of \( F = \{x_1 H, \ldots, x_n H\} \).

For each \( x_i \), form \( \tilde{x}_i \in Z_G \) as in equation (5.4). Then \( e \cdot kG \) is a free \( e \cdot kH \)-module of rank \( n \): \( e \cdot kG \) can be written as the internal direct sum

\[
e \cdot kG = \bigoplus_{i=1}^n \tilde{x}_i(e \cdot kH).
\]

Intersecting both sides of this equation with \( Z_G \) gives

\[
Z_G = \bigoplus_{i=1}^n \tilde{x}_i Z_H,
\]

showing that \( Z_G \) is a crossed product \( Z_H \ast F \), and is therefore isomorphic to \( k'[\![G/\Delta^+]\!] \ast F \). Lemma [5.10] may now be restated to say that this \( k'[\![H/\Delta^+]\!] \ast F \) is just a central 2-cocycle twist of \( k'[\![G/\Delta^+]\!] \). This is the map \( \tilde{\Psi} \), and the map \( \psi \) then also follows from Lemma [1.1(iii)].

Further, keeping the above notation, let \( A \) be an ideal of \( kH \) with \( M \subseteq A \). Continuing as before to write \( q : kG \to e \cdot kG \) for the natural quotient map, we see by Theorem [4.5] that \( \psi \circ q(A) = M_t(a) \) for some ideal \( a \) of \( k'[\![G/\Delta^+]\!] \).

**Corollary 5.12.** The following are equivalent:

1. \( A \) is \( G \)-stable as an ideal of \( kH \).
2. \( a \) is \( (G/\Delta^+) \)-stable as an ideal of \( k'[\![G/\Delta^+]\!] \).
3. \( a \) is \( (G/\Delta^+) \)-stable as an ideal of \( (k'[\![G/\Delta^+]\!])_\alpha \).

Moreover, when these conditions hold, we have

\[
\tilde{\psi} \circ q(A) = M_t\left( a \left( k'[\![G/\Delta^+]\!] \right)_\alpha \right).
\]

**Proof.** The equivalence of statements (ii) and (iii) is clear since, by definition, the conjugation action of \( G/\Delta^+ \) on the ring \( k'[\![G/\Delta^+]\!] \) is the same as the conjugation action of \( G/\Delta^+ \) on the ring \( (k'[\![G/\Delta^+]\!])_\alpha \). The equivalence of (i) and (ii) follows easily from Lemma [5.10]. Then

\[
\tilde{\psi} \circ q(A) = (\tilde{\psi} \circ q(A)) \cdot (\tilde{\psi} \circ q(kG)) = M_t(a) \cdot M_t\left( (k'[\![G/\Delta^+]\!]_\alpha \right) = M_t\left( a \left( k'[\![G/\Delta^+]\!] \right)_\alpha \right).
\]
Proof of Theorem B. This follows from the above theorem.

Proof of Theorem C. Statement (ii) follows from the above corollary, while (i) and (iii) follow from Corollary 3.3.
6 Peirce decomposition

From section 2 onwards, we often stipulated a stronger condition than in Lemma 1.1, namely that the conjugation action of $G$ on $kG$ should fix the idempotent $e$. In general, $e$ will have some non-trivial (but finite) $G$-orbit, so it will only make sense to consider $f \cdot kG$, where $f = e^G$.

The following result already gives us a lot of information:

**Lemma 6.1.** [8, 6.1.6] Let $R$ be a ring, and let $1 = e_1 + e_2 + \cdots + e_n$ be a decomposition of 1 into a sum of orthogonal idempotents. Let $G$ be a subgroup of the group of units of $R$, and assume that $G$ permutes the set $\{e_1, e_2, \ldots, e_n\}$ transitively by conjugation. Then $R \cong M_n(S)$, where $S$ is the ring $S = e_1 Re_1$.

For instance, if $M$ is a faithful minimal prime of $kG$, $e \in \text{cpi}^\perp \Delta^+$, and $f = e^G$, this lemma implies that

$$f \cdot kG \cong M_n(e \cdot kG \cdot e),$$

and it is easy to show that

$$e \cdot kG \cdot e = e \cdot kG_1,$$

where $G_1$ is the closed subgroup of elements of $G$ (here identified with the natural subgroup of $(f \cdot kG)^\perp$) that fix $e$ under conjugation.

**Proof of Theorem D.** This follows from Theorem B and Lemma 6.1.

Now, if $P$ is any ideal containing $M$, and the image of $f \cdot P$ in $M_n(e \cdot kG_1)$ is $M_n(e \cdot Q)$ for some ideal $Q$ (with $Q$ containing $JkG$, and $Q$ containing $1 - e$), it is easy to see that:

**Lemma 6.2.** $P$ is prime if and only if $Q$ is prime.

**Proof.** By Lemma 1.5, it suffices to show that $f \cdot P \cong M_n(e \cdot Q)$ is prime if and only if $e \cdot Q$ is prime; but this is true because Morita equivalence preserves primality (Lemma 1.7).

With a little more care, it is also possible to use the proof of Lemma 6.1 to show that

$$P^d = \bigcap_{g \in G} (Q^d)^g.$$

(See Lemmas 6.5 and 6.6 for a proof of this statement.)

In a future paper, we will show that certain prime ideals $P$ of $kG$ are controlled by certain closed normal subgroups $H$ containing $\Delta^+$. By Lemma 1.5 it clearly suffices to show that

$$(f \cdot P \cap f \cdot kH) f \cdot kG = f \cdot P.$$
If now $f = e|^{H}$, we may apply Lemma 6.1 to reduce to the case when $f = e$, and then apply the isomorphism $\psi$ of Theorem 5.11 and Lemma 1.6 to reduce the problem to a simpler one.

However, Lemma 6.1 is not always precise enough for our purposes. It may be the case that $f = e|^{G} \neq e|^{H}$, i.e. the $G$-orbit of $e$ splits into more than one $H$-orbit: then $f \cdot kH$ is not a full matrix ring, but a direct sum

$$f \cdot kH = \left(f^{(1)}_{H} \cdot kH \right) \oplus \cdots \oplus \left(f^{(s)}_{H} \cdot kH \right)$$

of several matrix rings (which may be non-isomorphic), and the same tools become messier to apply.

For this reason, it will be useful to keep track of the isomorphism in Lemma 6.1 more carefully, and so we will develop a more precise set of tools for handling this isomorphism.

Let $R$ be a ring, and fix a subgroup $G \leq R^{\times}$. Suppose we have a $G$-orbit of mutually orthogonal idempotents $e_{1}, \ldots, e_{r} \in R$ whose sum is 1. Recall the Peirce decomposition of $R$ with respect to this set of idempotents,

$$R = \bigoplus_{i,j=1}^{r} R_{ij} = \begin{pmatrix} R_{11} & R_{12} & \cdots & R_{1r} \\ R_{21} & R_{22} & \cdots & R_{2r} \\ \vdots & \vdots & \ddots & \vdots \\ R_{r1} & R_{r2} & \cdots & R_{rr} \end{pmatrix},$$

where $R_{ij} := e_{i}Re_{j}$.

Remark. Each $R_{ii}$ is naturally a ring with identity $1_{R_{ii}} = e_{i}$ under the multiplication inherited from $R$. Each $R_{ij}$ is an $(R_{ii}, R_{jj})$-bimodule, and the restriction of the multiplication map $R \otimes R \rightarrow R$ gives a homomorphism of $(R_{ii}, R_{kk})$-bimodules $R_{ij} \otimes R_{jk} \rightarrow R_{ik}$ for all $i, j, k$.

Let $A$ be any ideal of $R$, and write $A_{ij} = A \cap R_{ij} = e_{i}Ae_{j}$.

Lemma 6.3. $A_{ij}R_{kl} = \delta_{jk}A_{il}$ (where $\delta_{jk}$ is the Kronecker delta symbol).

Proof. If $j \neq k$, it is clear from the definitions that $A_{ij}R_{kl} = 0$.

Suppose $j = k$, and let $g \in G$ be such that $e_{k}g = ge_{l}$, so that $0 \neq e_{k}ge_{l} \in R_{kl}$. Then, given any $a \in A$, we can write

$$e_{i}ae_{l} = e_{i}a^{-1}ge_{l} = (e_{i}a^{-1}e_{k})(e_{k}ge_{l}),$$

showing that $A_{il} \subseteq A_{ik}R_{kl}$. The reverse inclusion is trivial. $\square$

In this section, we aim to study the relationship between an ideal $A \triangleleft R$ and the various ideals $A_{ii} \triangleleft R_{ii}$. To that end, write for convenience $S_{i} := R_{ii}$ and $B_{i} := A_{ii}$ from now on. Also, we have fixed the group $G$ inside $R^{\times}$: its analogue
inside $S^X_i$ is $e_iGe_i$, which we note is isomorphic to $G_i := CG(e_i)$ in the natural way.

Recall from Definition 1.4 that, if $I$ is an ideal of $kG$, we define

$$I^\dagger = (I + 1) \cap G = \ker(G \to (kG/I)^\times).$$

**Definition 6.4.** With notation as above,

$$A^\dagger = (A + 1_R) \cap G = \ker(G \to (R/A)^\times),$$

$$B^\dagger_i = (B_i + 1_{S_i}) \cap G_i = \ker(G_i \to (S_i/B_i)^\times).$$

The following lemma relates these groups.

**Lemma 6.5.**

(i) If $A \neq R$, then $A^\dagger \leq \bigcap_{i=1}^r G_i$.

(ii) $A^\dagger = \bigcap_{i=1}^r B^\dagger_i$.

(iii) The $\{B^\dagger_i\}$ are a $G$-orbit under conjugation.

**Proof.**

(i) Suppose not: then there exist some $i \neq j$ and some $g \in A^\dagger$ with $e_i g = ge_j$, so that $e_i g e_i = 0$. Then

$$g - 1 \in A \implies e_i (g - 1) e_i \in A \implies e_i \in A,$$

but then by conjugating by elements of $G$ we see that $e_k \in A$ for all $k$, and so $1 = \sum_k e_k \in A$, so $A = R$, which is a contradiction.

(ii) Fix $i$. If $g - 1 \in A$, then $g \in G_i$ by the previous lemma, so $e_i (g - 1) e_i \in B_i$.

(iii) $A$ is $G$-stable, so if $e_i^g = e_j$ then $B_i^g = (e_i A e_i)^g = e_j A e_j = B_j$. Also, $G_i^g = G_j$. It follows that $(B^\dagger_i)^g = B^\dagger_j$. $\square$

We finish by applying this to the problem mentioned at the beginning of this section. Recall the definition of control from Definition 1.3.

**Lemma 6.6.** Let $G$ be a compact $p$-adic analytic group, $H$ a closed normal subgroup containing $\Delta^+$, and $k$ a field of characteristic $p$. Let $P$ be an ideal of $kG$ containing a prime ideal.

Write $e \in cpl^{p,\Delta^+}_G(P)$, $f = e|G$, where the $G$-orbit of $e = e_1$ is $\{e_1, \ldots, e_r\}$. For each $1 \leq i \leq r$, write $G_i$ for the stabiliser in $G$ of $e_i$ (so that $e_i \cdot kG \cdot e_i = e_i \cdot kG_i$),

32
and similarly \( H_i = H \cap G_i \), and set \( Q_i \) equal to the preimage in \( kG_i \) of the ideal \( e_i \cdot e_i < e_i \cdot kG_i \).

Then

(i) \( P \) is controlled by \( H \) if and only if each \( Q_i \) is controlled by \( H_i \),

(ii) \( P^\dagger = \bigcap_{i=1}^r Q_i^\dagger \).

**Proof.** Take \( R \) to be \( f \cdot kG \), and identify \( G \) with its image in \((f \cdot kG)^\times\). Let \( A \) be the ideal \( f \cdot F \), and \( B_i \) the ideal \( e_i \cdot H_i \).

Write \( D = f \cdot kH \) and \( D_i = e_i \cdot kH_i \). By Lemma 1.5, it suffices to show:

\((A \cap D)R = A \iff (B_i \cap D_i)S_i = B_i \) for each \( i \).

|  ⇩ |
| Take the equation \((A \cap D)R = A \), and intersect it with \( S_i \). |

|  ⇪ |
| Note that \( \bigoplus_i B_i = \bigoplus_i (B_i \cap D_i)S_i \) by assumption, and we have automatically that \((A \cap D)R \subseteq A \). Since \( \bigoplus_i S_i \subseteq R \), we have that |

\[ \bigoplus_i B_i = \bigoplus_i (B_i \cap D_i)S_i \subseteq (A \cap D)R \subseteq A. \]

Hence

\[ \left( \bigoplus_i B_i \right) R \subseteq (A \cap D)R \subseteq AR = A, \]

i.e.

\[ \left( \bigoplus_i A_{ik} \right) \left( \bigoplus_{j,k} B_{jk} \right) \subseteq (A \cap D)R \subseteq A. \]

But the left hand side can easily be computed by Lemma 6.3 and is equal to

\[ \bigoplus_{i,k} A_{ik} \]

– that is, \( A \).

This shows that \( P \) is controlled by \( H \), completing the proof of (i).

Comparing Definitions 1.4 and 6.4, we can see that \( P^\dagger = A^\dagger \) and \( Q_i^\dagger = B_i^\dagger \).

Statement (ii) is now a direct consequence of Lemma 6.5(ii).

**Proof of Theorem E.** This is the content of Lemma 6.6.
