We present a new kind of monogamous relations based on concurrence and concurrence of assistance. For N-qubit systems $ABC_1...C_{N-2}$, the monogamy relations satisfied by the concurrence of N-qubit pure states under the partition $AB$ and $C_1...C_{N-2}$, as well as under the partition $ABC_1$ and $C_2...C_{N-2}$ are established, which give rise to a kind of restrictions on the entanglement distribution and trade off among the subsystems.

PACS numbers: 03.67.Mn,03.65.Ud

Quantum entanglement\textsuperscript{11,12} is an essential feature of quantum mechanics, which distinguishes the quantum from classical world. As one of the fundamental differences between quantum entanglement and classical correlations, a key property of entanglement is that a quantum system entangled with one of other systems limits its entanglement with the remaining others. In multipartite quantum systems, there can be several inequivalent types entanglement among the subsystems and the amount of entanglement with different types might not be directly comparable to each other. The monogamy relation of entanglement is a way to characterize the different types of entanglement distribution. The monogamy relations give rise to the structures of entanglement in the multipartite setting. Monogamy is also an essential feature allowing for security in quantum key distribution\textsuperscript{7}. Monogamy relations are not always satisfied by entanglement measures. Although the concurrence and entanglement of formation do not satisfy such monogamy inequality, it has been shown that the $\alpha = 2$ power of concurrence and $\alpha = \sqrt{2}$ power entanglement of formation for N-qubit states do satisfy the monogamy relations\textsuperscript{8}.

In this paper, we study the general monogamy inequalities satisfied by the concurrence and concurrence of assistance. We show that the concurrence of multi-qubit pure states satisfies some generalized monogamy inequalities.

The concurrence for a bipartite pure state $|\psi\rangle_{AB}$ is given by\textsuperscript{10,12}

$$C(|\psi\rangle_{AB}) = \sqrt{2[1 - Tr(\rho_A^2)]},$$

where $\rho_A$ is the reduced density matrix by tracing over the subsystem $B$, $\rho_A = Tr_B(|\psi\rangle_{AB}\langle\psi|)$. The concurrence is extended to mixed states $\rho = \sum_i\rho_i|\psi_i\rangle\langle\psi_i|$, $0 \leq \rho_i \leq 1$, $\sum_i\rho_i = 1$, by the convex roof extension,

$$C(\rho_{AB}) = \min_{\{p_i,|\psi_i\rangle\}} \sum_i p_i C(|\psi_i\rangle),$$

where the minimum is taken over all possible pure state decompositions of $\rho_{AB}$.

For a tripartite state $|\psi\rangle_{ABC}$, the concurrence of assistance is defined by\textsuperscript{13}

$$C_a(|\psi\rangle_{ABC}) \equiv C_a(\rho_{AB}) = \max_{\{p_i,|\psi_i\rangle\}} \sum_i p_i C(|\psi_i\rangle),$$

for all possible ensemble realizations of $\rho_{AB} = Tr_C(|\psi\rangle_{ABC}\langle\psi|) = \sum_i p_i |\psi_i\rangle_{AB}\langle\psi_i|$. When $\rho_{AB} = |\psi\rangle_{AB}\langle\psi|$ is a pure state, then one has $C(|\psi\rangle_{AB}) = C_a(\rho_{AB})$.

For an $N$-qubit state $|\psi\rangle_{A_1...A_{N-1}}$, the concurrence $C(|\psi\rangle_{A|B_1...B_{N-1}})$ of the state $|\psi\rangle_{A|B_1...B_{N-1}}$, viewed as a bipartite state with partition $A$ and $B_1B_2...B_{N-1}$, satisfies the Coffman-Kundu-Wootters inequality ($N = 3$)\textsuperscript{14} and its generalization to $N$-qubit case. In\textsuperscript{8,9} it has been shown that the concurrence of a state $\rho$ satisfies a more general monogamy inequality,

$$C_{AB_1B_2...B_{N-1}}^\alpha \geq C_{AB_1}^\alpha + C_{AB_2}^\alpha + ... + C_{AB_{N-1}}^\alpha,$$

where $\rho_{AB_i} = Tr_{B_1B_2...B_{i-1}B_{i+1}...B_{N-1}}(\rho)$, $C_{AB_i} = C(|\psi\rangle_{A|B_1...B_{N-1}})$, $C_{AB_{i+1}...B_{N-1}}(i = 1,...,N - 1)$ and $\alpha \geq \sqrt{2}$. The dual inequality in terms of the concurrence of assistance for $N$-qubit states has the form\textsuperscript{15},

$$C^2(|\psi\rangle_{A|B_1...B_{N-1}}) \leq \sum_{i=1}^{N-1} C^2(\rho_{AB_i}).$$

The concurrence\textsuperscript{11} is related to the linear entropy of a state $\rho$\textsuperscript{16},

$$T(\rho) = 1 - Tr(\rho^2).$$

For a bipartite state $\rho_{AB}$, $T(\rho)$ has property\textsuperscript{17},

$$|T(\rho_A) - T(\rho_B)| \leq T(\rho_{AB}) \leq T(\rho_A) + T(\rho_B).$$

\textbf{Theorem 1} For any $2 \otimes 2 \otimes ... \otimes 2 \otimes 2$ pure state $|\psi\rangle = |\psi\rangle_{ABC_1C_2...C_{N-2}}$, we have

$$C^2(|\psi\rangle_{AB|C_1C_2...C_{N-2}}) \geq \max \left\{ \sum_{i=1}^{N-2} [C^2(\rho_{AC_i}) - C_a^2(\rho_{BC_i})], \sum_{i=1}^{N-2} [C^2(\rho_{BC_i}) - C_a^2(\rho_{AC_i})] \right\}. $$
where $\rho_{AB} = Tr_{C_1 \ldots C_{N-2}}(|\psi\rangle\langle\psi|)$, $\rho_{AC_i} = Tr_{B_{C_1 \ldots C_{i-1} C_{i+1} \ldots C_{N-2}}}(|\psi\rangle\langle\psi|)$ and $\rho_{BC_i} = Tr_{A_{C_1 \ldots C_{i-1} C_{i+1} \ldots C_{N-2}}}(|\psi\rangle\langle\psi|)$.

[Proof] For any $2 \otimes 2 \otimes \ldots \otimes 2 \otimes 2$ pure state $|\psi\rangle_{ABC_1 \ldots C_{N-2}}$, one has:

$$C^2_{AB|C_1 \ldots C_{N-2}}(|\psi\rangle) = 2(1 - Tr \rho_{AB})$$

$$\geq |2(1 - Tr(\rho_A)) - 2(1 - Tr(\rho_B))|$$

$$= |C^2_{A|BC_1 \ldots C_{N-2}} - C^2_{B|AC_1 \ldots C_{N-2}}|,$$

the first inequality is due to the left inequality in (5).

For a $2 \otimes 2 \otimes m$ quantum pure state $|\psi\rangle_{ABC}$, it has been shown that $C^2_A(\rho_{AB}) = C^2(\rho_{AB}) + \frac{\tau^2}{2}(\rho_{ABC})$ [8], where $\tau^2 = C^2(\rho_{ABC}) = C^2_{A|BC} - C^2_{AB} - C^2_{AC}$ is the three tangle of concurrence. $C_{A|BC}$ is the concurrence of under bipartition $A|BC$ for pure state $|\psi\rangle_{ABC}$. $\rho_{ABC} = Tr_{C_{i}}(|\psi\rangle_{ABC}\langle\psi|)$ and $\rho_{A|BC} = C(\rho_{AB}(AC))$. Namely,

$$C^2_{A|BC_1 \ldots C_{N-2}} = C^2_A(\rho_{AB}) + C^2(\rho_{A|C_1 \ldots C_{N-2}}).$$

Hence we have

$$C^2_{AB|C_1 \ldots C_{N-2}}(|\psi\rangle) \geq C^2_{A|BC_1 \ldots C_{N-2}} - C^2_{B|AC_1 \ldots C_{N-2}}$$

$$\geq C^2(\rho_{A|C_1 \ldots C_{N-2}}) - \sum_{i=1}^{N-2} C^2_{a}(\rho_{BC_i})$$

$$\geq \sum_{i=1}^{N-2} C^2(\rho_{AC_i}) - \sum_{i=1}^{N-2} C^2_{a}(\rho_{BC_i})$$

where the second inequality is due to [1].

Similar to above derivation, by using that

$$C^2_{AB|C_1 \ldots C_{N-2}}(|\psi\rangle) \geq C^2_{A|BC_1 \ldots C_{N-2}} - C^2_{B|AC_1 \ldots C_{N-2}},$$

we can obtain another inequality in [6].

Theorem 1 shows that the entanglement contained in the pure states $|\psi\rangle_{ABC_1 \ldots C_{N-2}}$ is related to the sum of entanglement between bipartitions of the system.

The lower bound in inequalities (3) is easily calculable. As an example, let us consider the four-qubit pure state

$$|\psi\rangle_{ABCD} = \frac{1}{\sqrt{2}}(|0000\rangle + |1001\rangle).$$

We have $\rho_{ACD} = Tr_B(|\psi\rangle_{ABCD}\langle\psi|) = \frac{1}{2}(|0000\rangle + |1001\rangle)(|0000\rangle + |1001\rangle)$, $\rho_{BCD} = Tr_A(|\psi\rangle_{ABCD}\langle\psi|) = \frac{1}{2}(|000\rangle\langle000| + |001\rangle\langle001|)$, $C(\rho_{ACD}) = 0$, $C(\rho_{ACD}) = 1$ and $C(\rho_{BCD}) = C(\rho_{BCD}) = 0$. Therefore, $C(|\psi\rangle_{ABCD}) \geq 1$, namely, the state $|\psi\rangle_{ABCD}$ satisfies the inequality (3).

Theorem 1 gives a monogamy-type lower bound of $C(|\psi\rangle_{ABCD|C_2 \ldots C_{N-2}})$. According to the subadditivity of the linear entropy, we also have:

**Theorem 2** For any $2 \otimes 2 \otimes \ldots \otimes 2 \otimes 2$ pure state $|\psi\rangle_{ABC_1 \ldots C_{N-2}}$, we have

$$C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}}) \geq 2C^2(\rho_{AB}) + \sum_{i=1}^{N-2} (C^2_{a}(\rho_{AC_i}) + C^2_{a}(\rho_{BC_i})))$$

where $\rho_{AB} = Tr_{C_1 \ldots C_{N-2}}(|\psi\rangle\langle\psi|)$, $\rho_{AC_i} = Tr_{B_{C_1 \ldots C_{i-1} C_{i+1} \ldots C_{N-2}}}(|\psi\rangle\langle\psi|)$ and $\rho_{BC_i} = Tr_{A_{C_1 \ldots C_{i-1} C_{i+1} \ldots C_{N-2}}}(|\psi\rangle\langle\psi|)$.

[Proof] For any $2 \otimes 2 \otimes \ldots \otimes 2 \otimes 2$ pure state $|\psi\rangle_{ABC_1 \ldots C_{N-2}}$, one has

$$C^2_{AB|C_1 \ldots C_{N-2}}(|\psi\rangle)$$

$$= 2(1 - Tr(\rho_{AB}))$$

$$\leq |2(1 - Tr(\rho_A)) - 2(1 - Tr(\rho_B))|$$

$$= |C^2_{A|BC_1 \ldots C_{N-2}} - C^2_{B|AC_1 \ldots C_{N-2}}|,$$

the first inequality is due to the left inequality in (5).

For the four-qubit state (7), we have $C_a(\rho_{AB}) = C_a(\rho_{AC}) = C_a(\rho_{BC}) = 0$ and $C_a(\rho_{AD}) = 1$. Then from (8) we have $C(|\psi\rangle_{ABCD}) \leq 1$. The state $|\psi\rangle_{ABCD}$ also saturates the inequality (8).

From the Theorems 1 and 2, in fact, one has

$$|C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}}) - C^2(|\psi\rangle_{B|AC_1 \ldots C_{N-2}})|$$

$$\leq C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}})$$

$$\leq C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}}) + C^2(|\psi\rangle_{B|AC_1 \ldots C_{N-2}}).$$

(9) implies that if the systems B (A) and C_1 \ldots C_{N-2} are not entangled, then the entanglement between the systems A and C_1 \ldots C_{N-2} is equal to the entanglement between the systems A (B) and C_1 \ldots C_{N-2} for pure states $|\psi\rangle_{ABC_1 \ldots C_{N-2}}$.

From (9), we have $C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}}) \leq C^2(|\psi\rangle_{B|AC_1 \ldots C_{N-2}}) \leq C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}}) \leq C^2(|\psi\rangle_{B|AC_1 \ldots C_{N-2}})$. i.e., the sum of any two of $C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}})$, $C^2(|\psi\rangle_{B|AC_1 \ldots C_{N-2}})$ and $C^2(|\psi\rangle_{AB|C_1 \ldots C_{N-2}})$ is greater than or equal to the third. For convenience, we define $e = C^2_{AB|C_1 \ldots C_{N-2}}$, $a = C^2_{AB|C_1 \ldots C_{N-2}}$ and $b = C^2_{B|AC_1 \ldots C_{N-2}}$. In terms of (9), we can conclude that for any $2 \otimes 2 \otimes \ldots \otimes 2 \otimes 2$ pure state $|\psi\rangle_{AB|C_1 \ldots C_{N-2}}$, there are three vectors $\vec{a}$, $\vec{b}$ and $\vec{c}$ with lengths $a$, $b$ and $c$, respectively, which satisfy $\vec{c} = \vec{a} + \vec{b}$. For example, consider the pure state $|\varphi\rangle_{ABCD} = \frac{1}{\sqrt{2}}(|0000\rangle + |0010\rangle + |1010\rangle)$. We have $C(|\varphi\rangle_{ABCD}) = \frac{1}{2}$ and $C(|\varphi\rangle_{B|ACD}) = C(|\varphi\rangle_{B|ACD}) = \frac{1}{2}$. 

Then we have \( \vec{c} = \vec{a} + \vec{b} \), where \( \vec{a} = \frac{2}{\sqrt{3}} \hat{c}_1 + \frac{2}{\sqrt{9}} \hat{c}_2 \), \( \vec{b} = \frac{2}{9} \hat{c}_1 - \frac{2}{\sqrt{9}} \hat{c}_2 \), \( \vec{c} = \frac{4}{9} \hat{c}_1 \). \( \hat{c}_1 \) and \( \hat{c}_2 \) are two orthogonal basic vectors in a plane.

Now we consider further the generalized monogamy relations in terms of arbitrary partitions for the \( N \)-qubit generalized W-class states [19]:

\[
|W\rangle_{A_1...A_N} = a_1|1\cdots0\rangle_{A_1...A_N} + \cdots + a_N|0\cdots1\rangle_{A_1...A_N},
\]

where \( \sum_{i=1}^N |a_i|^2 = 1 \). One has \( C(\rho_{A_iA_j}) = C_0(\rho_{A_iA_j}) \) \((p \neq q \in \{1, ..., N\})\). Then (6) and (8) give rise to

\[
|C^2(\rho_{A_iA_j}) - C^2(\rho_{A_jA_i})| \leq 2C^2(\rho_{A_iA_j}) + \sum_{i \in \bar{I}} [C^2(\rho_{A_iA_i}) + C^2(\rho_{A_jA_j})],
\]

where \( 1 \leq i < j \leq N \), \( \{A_i/A_j\} = \{A_1...A_{i-1}A_{i+1}...A_{j-1}A_{j+1}...A_N\} \) and \( \bar{I} = \{1, 2, ..., i-1, i+1, ..., j-1, j+1, ..., N\} \).

The inequality Eq.(10) implies that the entanglement (square of concurrence) between \( A_iA_j \) and the other qubits cannot be more than the sum of the individual entanglements between \( A_i \) and each of the \( N-1 \) remaining qubits and the individual entanglements between \( A_j \) and each of the \( N-1 \) remaining qubits. Take 5-qubit generalized W-class states as an example, one has \( C^2_{AB|C_1C_2C_3} \leq \sum_{i=\{B,C_1C_2C_3\}} C^2(\rho_{A_i}) + \sum_{i=\{A,C_1C_2C_3\}} C^2(\rho_{B_i}) \), see Fig. 1.

**FIG. 1**: Generalized monogamy for five-qubit generalized W-class states.

Now we generalize our results to the concurrence \( C_{ABC_1|C_2...C_{N-2}} \) under partition \( ABC_1 \) and \( C_2...C_{N-2} \) for pure state \( |\psi\rangle_{ABC_1C_2...C_{N-2}} \), similar to the theorem 1 and the theorem 2, we can obtain the following corollaries:

**Corollary 1**: For any \( N \)-qubit pure state \( |\psi\rangle_{ABC_1C_2...C_{N-2}} \), we have

\[
C^2(|\psi\rangle_{ABC_1|C_2...C_{N-2}}) \geq \max \{ \sum_{i=1}^{N-2} C^2(\rho_{AC_i}) - \sum_{i=1}^{N-2} C^2(\rho_{BC_i}),
\]

\[
-2C^2(\rho_{AB}) - \sum_{i=1}^{N-2} \left( C^2(\rho_{AC_i}) + C^2(\rho_{BC_i}) \right),
\]

where \( J = \{A, B, C_2, ..., C_{N-2}\} \) and \( \rho_{C_{1j}} \) is the reduced density matrix by tracing over the subsystems except for \( C_1 \) and \( j \).

[proof] For any \( N \)-qubit pure state \( |\psi\rangle_{ABC_1C_2...C_{N-2}} \), we have

\[
C^2(|\psi\rangle_{ABC_1|C_2...C_{N-2}}) = 2(1 - Tr(\rho_{AB}^2)) \geq 2(1 - Tr(\rho_{AB}^2)) - 2(1 - Tr(\rho_{C_1}^2)) = C^2(|\psi\rangle_{ABC_1|C_2...C_{N-2}}),
\]

the first inequality is due to \( T(\rho_{AB}) \geq T(\rho_{AB}) - T(\rho_{C_1}) \). Combining Theorem 1 and (11), we obtain (12).

On the other hand, from the property of linear entropy, \( T(\rho_{ABC_1}) \geq T(\rho_{C_1}) - T(\rho_{AB}) \), we also can obtain the follow corollary.

**Corollary 2**: For any \( N \)-qubit pure state \( |\psi\rangle_{ABC_1...C_{N-2}} \), we have

\[
C^2(|\psi\rangle_{ABC_1|C_2...C_{N-2}}) \geq C^2(\rho_{AC_1}) + C^2(\rho_{BC_1}) + \sum_{i=2}^{N-2} C^2(\rho_{C_iC_i})
\]

\[
-2C^2(\rho_{AB}) - \sum_{i=1}^{N-2} \left( C^2(\rho_{AC_i}) + C^2(\rho_{BC_i}) \right),
\]

and

\[
C^2(|\psi\rangle_{ABC_1|C_2...C_{N-2}}) \leq 2C^2(\rho_{AB}) + \sum_{i=1}^{N-2} \left( C^2(\rho_{AC_i}) + C^2(\rho_{BC_i}) \right)
\]

\[
+ \sum_{j \in J} C^2(\rho_{C_{1j}}),
\]

where \( J \) and \( \rho_{C_{1j}} \) are defined as in Corollary 1.

In corollary 2, the upper bound is due to the right inequality of (11) and (12). Analogously, by use of \( T(\rho_{ABC_1}) \geq T(\rho_{AC_1}) - Tr(\rho_B) \), \( T(\rho_{ABC_1}) \geq T(\rho_A) - Tr(\rho_{BC_1}) \) and \( T(\rho_{ABC_1}) \leq T(\rho_A) + T(\rho_{BC_1}) + T(\rho_{AC_1}) + T(\rho_B) \), one can get more results like (11), (12) and (13).
The lower bounds in corollary 1 and corollary 2 are not equivalent. We consider the following two examples to show that corollary 1 and corollary 2 give rise to different lower bounds.

**Example 1:** Let us consider the pure state 
\[ |\psi\rangle_{ABC_1C_2C_3C_4} = \frac{1}{\sqrt{2}} (|000000\rangle + |101000\rangle). \]
We have
\[ C(\rho_{AB}) = C(\rho_{AC_1}) = C(\rho_{AC}) = C(\rho_{BC_1}) = C(\rho_{BC}) = 0 \text{ for } i = 2, 3, 4; C(\rho_{BC}) = C(\rho_{BC_1}) = 0 \text{ for } i = 1, 2, 3, 4, \text{ and } C(\rho_{AC_1}) = C(\rho_{AC}) = 1. \]
Thus \( C(|\psi\rangle) \geq 1 \) from (11) and \( C(|\psi\rangle) \geq 0 \) from (12). Namely bound (11) is better than (12) in this case.

**Example 2:** For the state 
\[ |\psi\rangle_{ABC_1C_2C_3C_4} = \frac{1}{\sqrt{2}} (|000000\rangle + |001100\rangle), \]
it is straightforward to calculate that
\[ C(\rho_{AB}) = C(\rho_{AC_1}) = C(\rho_{AC}) = C(\rho_{BC_1}) = C(\rho_{BC}) = 0, \text{ for } i = 1, 2, 3, 4 \text{ and } C(\rho_{BC}) = C(\rho_{BC_1}) = 1. \]
Hence \( C(|\psi\rangle) \geq 0 \) from (11), \( C(|\psi\rangle) \geq 1 \) from (12) and bound (12) is better than (11) for this state.

We have presented the generalized monogamy relations of concurrence for \( N \)-qubit systems, by showing the relations among \( C(|\psi\rangle_{AB|C_1...C_{N-2}}), C_{AB}, C_{AC_1}, C_{BC_1}, C_a(\rho_{AC}), \) and \( C_a(\rho_{BC}), 2 \leq i \leq N - 2, \) which give rise to the lower and upper bounds on the entanglement sharing among the partitions. Theorem 1 (Theorem 2) gives a lower (an upper) bound of \( C(|\psi\rangle_{AB|C_1...C_{N-2}}). \) It has been shown that although \( C(|\psi\rangle_{AB|C_1...C_{N-2}}), C(|\psi\rangle_{ABC_1...C_{N-2}}), \) and \( C(|\psi\rangle_{B|AC_1...C_{N-2}}) \) do not satisfy relation like \( C_2(|\psi\rangle_{AB|C_1...C_{N-2}}) = C^2(|\psi\rangle_{A|BC_1...C_{N-2}}) + C^2(|\psi\rangle_{B|AC_1...C_{N-2}}), \) they do satisfy the triangle inequality: the sum of any two of them is greater or equal to the third.

Entanglement monogamy is a fundamental property of multipartite entangled states. We have presented a new kind of monogamy relations satisfied by the concurrence of \( N \)-qubit pure states under partition \( AB \) and \( C_1...C_{N-2} \) as well as under partition \( ABC_1 \) and \( C_2...C_{N-2}. \) These relations also give rise to a kind of trade off relations related to the lower and upper bounds of concurrences. Similar results can be obtained for concurrences under arbitrary partitions \( ABC_1...C_i|C_{i+1}...C_{N-2} (2 \leq i < N - 1). \) Such restrictions on entanglement distribution may be also true for other measures of quantum correlations like negativity or quantum discord.
