**Abstract**

**Background:** <i>Pseudomonas aeruginosa</i> is a pathogenic bacterium, causing nosocomial infections with intrinsic and acquired resistance mechanisms to a large group of antibiotics, including β-lactams. This study aimed to determine the susceptibility pattern to selected antibiotics and to index the first reported β-lactamases genes frequency in <i>Ps. aeruginosa</i> in Khartoum State, Sudan.

**Methods:** 121 <i>Ps. aeruginosa</i> clinical isolates from various clinical specimens were used in this cross sectional study conducted in Khartoum State. Eighty isolates were confirmed as <i>Ps. aeruginosa</i> through conventional identification methods and species specific primers. The susceptibility pattern of the confirmed isolates to selected antibiotics was done following the Kirby Bauer disk diffusion method. Multiplex PCR was used for detection of seven β-lactamase genes.
genes (blaTEM, blaSHV, blaCTXM-1, blaVEB, blaOXA-1, blaAmpC and blaDHA).

**Results:** Of the 80 confirmed *Ps. aeruginosa* isolates, 8 (10%) were resistant to Imipenem while all isolates were resistant to Amoxicillin and Amoxyclav (100%). A total of 43 (54%) *Ps. aeruginosa* isolates were positive for blaTEM, blaSHV, blaCTXM-1, blaVEB and blaOXA-1 genes, while 27 (34%) were positive for class C β-Lactamases, and 20 (25%) were positive for both classes. Frequency of beta-lactamases genes was as follows: blaTEM, 19 (44.2%); blaSHV, 16 (37.2%); bla CTX-M-1, 10 (23.3%); blaVEB, 14 (32.6%); blaOXA-1, 7 (16.3%). blaAmpC 22 (81.5%) and bla DHA 8 (29.6%). In total, 3 (11.1%) isolates were positive for both bla AmpC and blaDHA genes.

**Conclusion:** *Ps. aeruginosa* isolates showed a high rate of β-lactamases production, with co-resistance to other antibiotic classes. The lowest resistance rate of *Ps. aeruginosa* was to Imipenem followed by Gentamicin and Ciprofloxacin. No statistically significant relationship between production of β-lactamases in *Ps. aeruginosa* and resistance to third generation cephalosporins was found.

Introduction

*Pseudomonas aeruginosa* is one of the leading causes of nosocomial infections worldwide with high mortality rates, particularly among immunocompromised patients. *P. aeruginosa* infections are difficult to treat, due to its extraordinary antimicrobial resistance to all available classes of antimicrobial agents, including β-lactams, aminoglycosides and fluoroquinolones. Resistance to β-lactams occurs by different mechanisms, including bla<sup>ampC</sup> overexpression due to genetic mutations, mutant gene acquisition, overproduction of efflux system, or low permeability. β-lactamases refer to enzymes that hydrolyze the amide bond of the β-lactam ring leading to drug inactivation and therapy failure. β-lactamases are classified molecularly into four groups: class A (extended spectrum β-lactamases (ESBLs)), class B (metallo-β-lactamases), class C (cephalosporinases), and class D (oxacillinases).

ESBLs are enzymes that extend their hydrolyzing ability to hydrolyze broad spectrum cephalosporins and they also confer resistance to penicillins and narrow spectrum cephalosporins. ESBLs are inhibited by β-lactamase inhibitors, such as clavulanic acid. β-lactamases are transformed to ESBLs usually after point mutations in the β-lactamases gene. These mutations alter the substrate specificity because of changes in the amino acid sequences near the enzyme active site. ESBLs producing *P. aeruginosa* have been reported worldwide in different countries.

AmpC β-lactamases are class C cephalosporinases that mediate bacterial resistance to cephalosporins and cephemycins. They also exhibit low rates of monobactam, cefepime and carbapenem hydrolysis and usually resist the inhibition by clavulanic acid. Normally, AmpC is a chromosomal β-lactamase gene that is regulated by ampR gene and expressed constantly. Point mutations of ampR gene in *Enterobacter cloacae* activate AmpC that mediate resistance to β-lactams. In *P. aeruginosa* over expressed AmpC β-lactamase mediate the resistance to broad spectrum cephalosporins. AmpC β-lactamase in *P. aeruginosa* has also been reported in different countries around the world.

The exact frequency of β-lactamase producing *P. aeruginosa* in Khartoum State, Sudan is unknown; therefore, the aim of this study was to determine the susceptibility pattern to selected antibiotics and to determine the frequency of β-lactamases producing *P. aeruginosa* isolates collected in Khartoum State hospitals.

**Methods**

**Study design**

This is a cross-sectional study conducted between February 2017 and October 2017. Ethical approval for the study was obtained from the ethical committee of the College of Medical Laboratory Science, Sudan University of Science and Technology (SUST) (ethical meeting no, SUST/DSR/IEC/EAA2/2017; data, 07th January 2017). Written informed consent from participants was waived by the same ethical committee as the study only used previously collected human bio-specimens with limited participant data.

**Collection and identification of bacterial strains**

A total of 80 *P. aeruginosa* clinical isolates were obtained from Soba Teaching Hospital, Elribat University Hospital, National Laboratory for Public Health, Ear Nose Throat Hospital, and Military Hospital in Khartoum State. When there was a positive confirmation of *P. aeruginosa*, the study supervisor went and collected the sample from the hospital. The samples were collected from patients suffering from urinary tract infections, respiratory tract infections, blood infections, and wound and ear infections. Data pertaining to the site of infection was collected from hospital records. The bacteria were preserved in 20% glycerol and peptone water and stored at -20°C.

Phenotypic identity of the isolates was confirmed through conventional bacterial identification methods, such as Gram stain, oxidase test, and reactions in media containing sugars, such as Kligler Iron Agar, urease test and, citrate test. Pigment production was assessed using Muller Hinton agar, and then phenotypic identity confirmed by genotypic characterization using multiplex PCR, as previously described.

**Antimicrobial susceptibility testing**

Muller Hinton medium (HiMedia, India) was prepared and sterilized as instructed by the manufacturer. Antimicrobial susceptibility testing was performed following the modified Kirby-Bauer disc diffusion method and the results interpreted according to Clinical Laboratory Standards Institute guidelines (CLSI, 2007). The following antimicrobial discs (HiMedia, India) were used for sensitivity testing: Amoxicillin (25 µg), Cefotaxime (30 µg), Amoxicillin-Clavulanic acid (30 µg), Gentamicin (10 µg), Ciprofloxacin (5 µg), Chloramphenicol (30 µg) and Imipenem (10 µg). *P. aeruginosa* ATCC 27853 was used as quality control strain to control the performance of the test and ensure that the test is properly performed.

Phenotypic identity of the isolates was confirmed through conventional bacterial identification methods such as Gram stain, oxidase test, reactions in media containing sugars such as Kligler Iron Agar, urease test and citrate test.
Genotypic analysis of bacterial isolates

Genomic DNA was extracted by simple boiling method\textsuperscript{18}. The extracted DNA was used as a template for amplification of target genes using multiplex PCR using TECHNE TC-312 (UK) thermocycler. Firstly, oprI and oprL, primers (Table 1) (Macrogen, Korea) were used to confirm the identification of \textit{P. aeruginosa}. Seven primer pairs (Table 1) (Macrogen, Korea) were used for detection of β-lactamases genes (\textit{bla}_{TEM}, \textit{bla}_{SHV}, \textit{bla}_{CTXM-1}, \textit{bla}_{VER}, \textit{bla}_{OXA-1}) and class C genes (\textit{bla}_{AmpC} and \textit{bla}_{DHA}). The oprI and oprL reaction was carried out with the following cycling conditions: denaturation at 95°C for 5 min; 33 cycles of denaturation at 95°C for 30 secs, annealing at 58°C for 30 sec and extension at 72°C for 30 secs, and final extension at 72°C for 5 min\textsuperscript{28}.

β-lactamases detection was done in two batches; the first batch was used for detection of \textit{bla}_{TEM}, \textit{bla}_{SHV}, \textit{bla}_{CTXM-1}, \textit{bla}_{AmpC} and \textit{bla}_{OXA}, while the second batch was used for detection of \textit{bla}_{VER} and \textit{bla}_{OXA-1} genes. The first batch detection was done in 20 µl of final reaction mixture using Maxime PCR Premix kits (iNtRON Biotechnology, Korea), containing 13 µl of double distilled water (DDW), 0.3µl of each five forward and 0.3 µl of each reverse primers (1.5 µl), 2 µl of Dimethyl sulfoxide (DMSO) and 2 µl of template DNA. Amplification of the second batch was done in 20µl using Maxime PCR Premix kits (iNtRON Biotechnology, Korea), containing 14.4 µl of DDW, 0.4 µl of each two forward and 0.4 µl of each two reverse primers (0.8 µl), 2 µl of DMSO and 2 µl of template DNA. Cycling conditions for both amplification reactions were as follows: initial denaturation at 94°C for 2 minutes, then 35 cycles of denaturation at 94°C for 30 secs, annealing at 54°C for 30 secs and extension at 72°C for 50 secs, and final extension at 72° for 5 minutes.

Amplified products were analyzed by electrophoreses at 80 volts for 20 minutes on 1.5% agarose gel containing ethidium bromide and then visualized using UV transilluminator (Uvitec–UK) with 50bp or 100bp molecular DNA ladder (iNtRON Biotechnology, Korea).

Data analysis

Statistical analysis of the data was performed using chi-square test (level of significance was 0.05) with SPSS software version 20 and GraphPad prism 5 demo.

Results

From 121 clinical isolates collected from different hospitals in Khartoum State, only 80 (66%) were confirmed as \textit{P. aeruginosa}.

| VEB         | F       | CATCCTGGATCAAAAGCCTG | 648              | 34         |
|             | R       | CGAAATTTTCTTGGAACCTCG |                   |            |
| OXA-1       | F       | GGCACCAAGTTCACCTTCAAG | 564              | 35         |
|             | R       | GACCCCAAGTTCTCTGTAAGTG |                   |            |
through conventional methods and species-specific primers; the remaining 41 (34%) isolates were considered as other Gram-negative rod bacteria. The distribution of clinical isolates according to site of infection was as follows: urine, 34 (42%); wound swab, 24 (30%); ear swab, 8 (10%); sputum, 8 (10%); and blood, 6 (7.5%).

The results of antimicrobial susceptibility test for selected antibiotics are presented in Table 2.

Out of 80 P. aeruginosa isolates, 54 (68%) were Pyocyanin pigment producers, while 26 (32%) were not pigment producers. There was a significant association between pyocyanin pigment production and site of infection ($P=0.000$) (Figure 1). There was also a significant association between pigment production and resistance to Chloramphenicol ($P=0.020$) and Cefotaxime ($P=0.000$), while there was insignificant association between pigment production and resistance to other antimicrobials used in this study (Figure 2).

Molecular detection of β-lactamases showed that 43 (54%) of the isolates were positive for at least one β-lactamases gene, while 37 (46%) were negative for all genes (Figure 3). The frequency of each gene presence among P. aeruginosa was as follows: bla$_{TEM}$, 19 (44.2%); bla$_{SHV}$, 16 (37.2%); bla$_{CTX,M}$, 10 (23.3%); bla$_{VEB}$, 14 (32.6%); and bla$_{OXA,1}$, 7 (16.3%). There was a significant association between the presence of bla$_{TEM}$, bla$_{SHV}$, bla$_{CTX,M}$, bla$_{VEB}$ or bla$_{OXA,1}$ genes in P. aeruginosa and site of infection ($P=0.030$) (Figure 3). Co-presence of more than one of bla$_{TEM}$, bla$_{SHV}$, bla$_{CTX,M}$, bla$_{VEB}$ or bla$_{OXA,1}$ gene among P. aeruginosa clinical isolates is presented in Table 3.

Class C β-lactamases gene were positive in 27 (34%) P. aeruginosa isolates; while 53 (66%) were negative (Figure 4). The frequency of class C β-lactamases genes was as follows: bla$_{AmpC}$, 22 (81.5%); bla$_{DHA}$, 8 (29.6%); and 3 (11.1%) isolates were positive for both genes. Association between presence of Class C β-lactamases genes and site of infection was insignificant ($P=0.215$) (Figure 4).

In total, 25% of P. aeruginosa isolates were positive for both β-lactamase (bla$_{TEM}$, bla$_{SHV}$, bla$_{CTX,M}$, bla$_{VEB}$ or bla$_{OXA,1}$) and class C β-lactamase genes (Figure 5). Co-presence of β-lactamases genes and class C β-lactamase among P. aeruginosa clinical isolates is presented in Table 4.

Class C β-lactamases gene were positive in 27 (34%) P. aeruginosa isolates; while 53 (66%) were negative (Figure 4). The frequency of class C β-lactamases genes was as follows: bla$_{AmpC}$, 22 (81.5%); bla$_{DHA}$, 8 (29.6%); and 3 (11.1%) isolates were positive for both genes. Association between presence of Class C β-lactamases genes and site of infection was insignificant ($P=0.215$) (Figure 4).

In total, 25% of P. aeruginosa isolates were positive for both β-lactamase (bla$_{TEM}$, bla$_{SHV}$, bla$_{CTX,M}$, bla$_{VEB}$ or bla$_{OXA,1}$) and class C β-lactamase genes (Figure 5). Co-presence of β-lactamases genes and class C β-lactamase among P. aeruginosa clinical isolates is presented in Table 4.

**Discussion**

*Pseudomonas aeruginosa* is one of the main causative agents of serious nosocomial infections with increased reports of β-lactams resistant strains that makes treatment difficult and complicated. Production of β-lactamases is one of the most common mechanisms of β-lactam resistance.
Table 3. Number of *Pseudomonas aeruginosa* isolates exhibiting co-presence of *bla*<sub>TEM</sub>, *bla*<sub>SHV</sub>, *bla*<sub>CTX-M-1</sub>, *bla*<sub>VEB</sub> or *bla*<sub>OXA-1</sub> β-lactamases genes.

|   | *bla*<sub>TEM</sub> | *bla*<sub>SHV</sub> | *bla*<sub>CTX-M-1</sub> | *bla*<sub>VEB</sub> | *bla*<sub>OXA-1</sub> |
|---|---------------------|---------------------|-------------------------|---------------------|-----------------------|
| *bla*<sub>TEM</sub> | 7                   | 6                   | 5                       | 3                   | 1                     |
| *bla*<sub>SHV</sub> | 6                   | 4                   | 4                       | 4                   | 1                     |
| *bla*<sub>CTX-M-1</sub> | 5                    | 4                   | 0                       | 1                   | 1                     |
| *bla*<sub>VEB</sub> | 3                   | 4                   | 1                       | 3                   | 3                     |
| *bla*<sub>OXA-1</sub> | 1                   | 1                   | 1                       | 3                   | 2                     |

**Figure 2.** Frequency of *Pseudomonas aeruginosa* pigment producing isolates according to antimicrobial resistance.

**Figure 3.** Frequency of β-lactamases (*bla*<sub>TEM</sub>, *bla*<sub>SHV</sub>, *bla*<sub>CTX-M-1</sub>, *bla*<sub>VEB</sub> or *bla*<sub>OXA-1</sub>) among *Pseudomonas aeruginosa* isolates site of infection.
In this study the frequency of β-lactamases genes among P. aeruginosa isolates was 53.8%. This frequency is close to a report from India by Qureshi and Bhatnagar (2016)\textsuperscript{15}, where the frequency of β-lactamases in P. aeruginosa isolates was 46%. However, the results of this study disagree with another report from India by Gupta et al. (2016)\textsuperscript{18} where the frequency of β-lactamases in P. aeruginosa isolates was 22.9%. These discrepancies could be due to differences in strains of the clinical isolates, the antibiotics used or sample size.

The most abundant gene among the β-lactamases (bla\text{\textit{qep}}, bla\text{\textit{shv}}, bla\text{\textit{CTX-M}}, bla\text{\textit{VEB}}, bla\text{\textit{OKA-1}}) producing P. aeruginosa isolates detected in this study was bla\text{\textit{TEM}} gene (19, 44.2%), followed by bla\text{\textit{SHV}}, bla\text{\textit{VEB}}, bla\text{\textit{CTX-M}} and bla\text{\textit{OKA-1}} (16 (37.2%), 14 (32.6%), 10 (23.3%) and 7 (16.3%), respectively). Similar results were reported by Salah et al. (2016)\textsuperscript{9} in Egypt concerning the presence of bla\text{\textit{qem}}, bla\text{\textit{shv}} and bla\text{\textit{OKA-1}} (50%, 33% and 17%, respectively). The frequency of bla\text{\textit{TEM}} gene is also similar to that reported by Rafiee et al. (2014)\textsuperscript{9}, which was present in 39.2% of isolates. In a study in Iran by Sales et al. (2017)\textsuperscript{11}, similar results were reported concerning the presence of bla\text{\textit{CTX-M}} (27.3%), while in India Jamali et al. (2017)\textsuperscript{11} reported a higher frequency (57.5%) of this gene.

On the other hand, the frequency of bla\text{\textit{VEB}} and bla\text{\textit{SHV}} genes in this study differs from that reported in Iran by Bokaian et al. (2014)\textsuperscript{22} where bla\text{\textit{VEB}} gene frequency was 13.3%, while the frequency of bla\text{\textit{SHV}} gene was 6.6%. The report by Jamali et al. (2017)\textsuperscript{13} concerning the genes bla\text{\textit{qem}} (15%) and bla\text{\textit{shv}} (75%) are also different from those reported in this study, and this could be due to the variation in strains of clinical isolates and the sample size used.

In this study, the frequency of class C β-lactamase genes in P. aeruginosa isolates was 27 (34%). This result is close to a report from India by Gupta et al. (2016)\textsuperscript{18} where 43% of P. aeruginosa were AmpC producers, and disagrees with a report from Thailand by Katvoravutthichai et al. (2016)\textsuperscript{13} where 11% of P. aeruginosa isolates were AmpC producers. In this study, out of the class C β-lactamase producing P. aeruginosa isolates, 22 (81.5%) and 8 (29.6%) isolates were positive for bla\text{\textit{ampC}} and bla\text{\textit{DHA}} genes, respectively. Qureshi and Bhatnagar (2016)\textsuperscript{11} in India reported that no P. aeruginosa isolates were positive for bla\text{\textit{ampC}} gene, while Rafiee et al. (2014)\textsuperscript{9} in Iran reported that 60.8% of P. aeruginosa were positive for bla\text{\textit{ampC}} gene.

All P. aeruginosa clinical isolates tested in our study were resistant to Amoxicillin and Amoxicillin/clavulanate and this may be due to the misuse of antibiotics in Sudan\textsuperscript{14}, where plenty of antimicrobial agents are sold over the counter. This rate of resistance is higher than the rate of resistance reported by Ahmad et al. (2016)\textsuperscript{14} in Pakistan where the resistance to Amoxicillin and Amoxicillin/clavulanate was 73.4% and 67.7% respectively, and this could be justified by the time difference between the studies, as well as the difference in the strains and antibiotics used.

The resistance rate of P. aeruginosa to Imipenem was 10% (n=8). This may be due to the infrequent use of Imipenem antibiotics. This percentage agrees with a study reported in Pakistan by Ahmad et al. (2016)\textsuperscript{14} where 11.1% of P. aeruginosa isolates were resistant to Imipenem, while in Sudan Altom and Ahmed (2015)\textsuperscript{16} reported that 5.7% P. aeruginosa isolates were resistant to Imipenem. This finding may indicate that carbapenem resistance is on the rise in P. aeruginosa isolates from Sudan.

In this study, the number of P. aeruginosa isolates resistant to Cefotaxime, Chloramphenicol and Ceftazidime was 71 (88.8%), 71 (88.8%) and 46 (57.5%), respectively. The rate of resistance to Cefotaxime in this study is different from that reported in

---

**Figure 4. Frequency of class C genes among Pseudomonas aeruginosa isolates and site of infection.**
Pakistan by Ahmad et al. (2016) who found that 20.3% of P. aeruginosa isolates were resistant to Ceftazidime. The resistance rate in this study also disagrees with that reported by Albadawi (2010) in Sudan who found that resistance of P. aeruginosa to Ceftazidime and Cefotaxime were 31% and 42%, respectively. These findings also indicate the rapidly increasing rates of P. aeruginosa resistance to antimicrobial agents in Sudan perhaps due to antibiotic misuse.

In this study, there was significant association between β-lactamases production and site of infection (P=0.030). P. aeruginosa isolated from blood showed the highest production of blaTEM, blaSHV, blaCTXM-1, blaVEB and blaOXA-1 genes followed by ear swab, urine, sputum and wound swab. This result agrees with a study in India reported by Basak et al. (2012) where the highest β-lactamases producing P. aeruginosa isolates were from blood, but disagrees with Azizi et al. (2015) in Iran who found that highest production was in P. aeruginosa isolated from wound followed by urine, sputum and blood. There was insignificant association between the presence of class C β-lactamase genes and site of infection (P=0.215) found in the present study. The highest frequency of class C β-lactamase genes in P. aeruginosa were isolated from blood followed by urine, ear swab, wound swab and sputum. These results agree with the study in India reported by Basak et al. (2012) in that the highest percentage of class C β-lactamase genes in P. aeruginosa were found in blood.

In this study, the frequency of pigment producing P. aeruginosa isolates was 67.5%. In a study in India a higher percentage was reported where out of 38 phenotypically β-lactamases-negative isolates, 20 isolates were positive for β-lactamases genes.

In this study, the frequency of pigment producing P. aeruginosa isolates was 67.5%. In a study in India a higher percentage was reported where 82.5% of P. aeruginosa were pigment producers.

Pakistan by Ahmad et al. (2016) who found that 20.3% of P. aeruginosa isolates were resistant to Ceftazidime. The resistance rate in this study also disagrees with that reported by Albadawi (2010) in Sudan who found that resistance of P. aeruginosa to Ceftazidime and Cefotaxime were 31% and 42%, respectively. These findings also indicate the rapidly increasing rates of P. aeruginosa resistance to antimicrobial agents in Sudan perhaps due to antibiotic misuse.

In this study, there was significant association between β-lactamases production and site of infection (P=0.030). P. aeruginosa isolated from blood showed the highest production of blaTEM, blaSHV, blaCTXM-1, blaVEB and blaOXA-1 genes followed by ear swab, urine, sputum and wound swab. This result agrees with a study in India reported by Basak et al. (2012) where the highest β-lactamases producing P. aeruginosa isolates were from blood, but disagrees with Azizi et al. (2015) in Iran who found that highest production was in P. aeruginosa isolated from wound followed by urine, sputum and blood. There was insignificant association between the presence of class C β-lactamase genes and site of infection (P=0.215) found in the present study. The highest frequency of class C β-lactamase genes in P. aeruginosa were isolated from blood followed by urine, ear swab, wound swab and sputum. These results agree with the study in India reported by Basak et al. (2012) in that the highest percentage of class C β-lactamase genes in P. aeruginosa were found in blood.

In this study, the frequency of pigment producing P. aeruginosa isolates was 67.5%. In a study in India a higher percentage was reported where 82.5% of P. aeruginosa were pigment producers.
Moreover, those of Imipenem, followed by Gentamicin and Ciprofloxacin. The best antibiotic sensitivity results obtained in this study were resistant to Amoxicillin and Amoxicillin/clavulanate. Since all the strains of P. aeruginosa are becoming useless for treating this problematic bacterium, this study confirms the reports that a number of antibiotics are becoming useless for treating this problematic bacterium, especially in Sudan. This study raises attention to the problem of resistance to β-lactams in P. aeruginosa in Sudan. This study confirms the reports that a number of antibiotics are becoming useless for treating this problematic bacterium, since all the strains of P. aeruginosa in this study were resistant to Amoxicillin and Amoxicillin/clavulanate. The best antibiotic sensitivity results obtained in this study were those of Imipenem, followed by Gentamicin and Ciprofloxacin. Moreover, P. aeruginosa isolates showed an increased rate of β-lactamase production with co-resistance with other classes of antibiotics. Of interest is the finding that clinical isolates were resistant phenotypically in high frequencies to Amoxicillin, Amoxicillin/clavulanate and a third generation antibiotic, Cefotaxime, and showed negative results genotypically, indicating that resistance to this family of antibiotics also exist by resistance mechanisms other than β-lactamases production. Also, our PCR results revealed that P. aeruginosa possesses hidden β-lactamases genes that can’t be detected phenotypically. Finally, this study highlighted for the first time the problem of misidentification of P. aeruginosa and other microorganisms in Khartoum hospitals as only 80 out of the 120 alleged isolates were confirmed to be P. aeruginosa through PCR.

The manuscript “Extended spectrum β-lactamases and class C β-lactamases gene frequency in Pseudomonas aeruginosa isolated from various clinical specimens in Khartoum State, Sudan: a cross sectional study” describe important findings on drug resistance (ESBL and Class C Beta lactamases) of P. aeruginosa in Khartoum State, Sudan. The author claimed the study to be the first one to describe the exact frequency of ESBL producing P. aeruginosa in Khartoum, Sudan.

On the whole the research is scientifically carried out and written. Following are few minor suggestions

○ In the abstract section, the author has mentioned that 40 isolates were other bacterial species. I think the objective of the study is the molecular detection of beta lactamases in P. aeruginosa so there is no need mention about other bacterial species.

○ The statement “121 Ps. aeruginosa clinical isolates from various clinical specimens were used in this cross-sectional study conducted in Khartoum State. A total of 80 isolates were confirmed as Ps. aeruginosa through conventional identification methods and species specific primers” is really confusing. If 80 P. aeruginosa isolates were finally analyzed for drug resistance then there no need to state 121 P. aeruginosa clinical isolates.

○ As mentioned above the focus of manuscript is drug resistance in P. aeruginosa, so the irrelevant information such as Pyocyanin pigment production should be deleted.

○ Though in methodology section, the author has claimed statistical tests (chi square, p value), but there is no information on statistical tests in figures. I think statistical values should be included in figures.

○ In all tables, please proper define the abbreviations, number and percentage (n(%) in foot note.

○ Figures should be properly labeled (Frequency (n)).
The percentage should be added in all tables, as it will help the readers to understand and interpret the tables in better way.

Some of the references are inconsistent/incomplete which should be arranged as per journal format.

Is the work clearly and accurately presented and does it cite the current literature?
Yes

Is the study design appropriate and is the work technically sound?
Yes

Are sufficient details of methods and analysis provided to allow replication by others?
Yes

If applicable, is the statistical analysis and its interpretation appropriate?
Partly

Are all the source data underlying the results available to ensure full reproducibility?
Yes

Are the conclusions drawn adequately supported by the results?
Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Medical Microbiology

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Author Response 19 Dec 2020

Dina Naser, Central Laboratory, Khartoum, Sudan

Thank you for these comments, minor changes have been done following the reviewer’s comments. Changes include specifying the final included sample size, addition of results percentages to the tables with minor edits in the figures titles and in the abstract the Beta-lactamases genes naming changed according to the title.

Competing Interests: No competing interests were disclosed.

Yes

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** microbiology, public health

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
Nobumichi Kobayashi
Department of Hygiene, Sapporo Medical University School of Medicine, Sapporo, Japan

This is a kind of primitive study that provides only limited information. Only importance is that this study was done in Sudan. However, still number of isolates were low, and errors in descriptions of technical terms are found in this manuscript.

1. Abstract: Number of \( P. \textit{aeruginosa} \) should be written as "80". "121" should not appear here, because 41 isolates were not \( P. \textit{aeruginosa} \).

2. "\textit{Ps. aeruginosa}" should be corrected as "\textit{P. aeruginosa}" as formal abbreviation.

3. Amoxyclav may be a commercial name of the drug. It should be written as general name. Maybe it is "amoxicillin/clavulanate".

4. Authors may have serious misunderstanding regarding the term of ESBL. NOT all of TEM, SHV, OXA type beta-lactamases are ESBL. TEM-1, 2, SHV-1, OXA-1 are not ESBL. Other subtypes of TEM, SHV, and OXA are called as "ESBL". Those subtypes can be identified only by sequencing of full-length ORF of these genes. In this manuscript, only CTX-M type gene can be called as "ESBL". However, it is not sure that TEM, SHV, OXA type genes are ESBL genes or not, because sequence was not determined. In this regard, this manuscript must be revised substantially. Authors can mention CTX-M as ESBL, others should not be referred as ESBL, but just individual enzyme names, e.g., "TEM gene". According to this alteration, whole manuscript should be rewritten.

5. CTX-M-1 should be written as "CTX-M-1 group". CTX-M types cannot be determined by only PCR. Authors should read and study literature on ESBL and beta lactamases of bacteria, to exactly understand their nomenclature and definition.

6. Table 3 cannot be understood. Authors should make a table to show combination pattern of beta-lactamases and their frequency.

7. Figure 5: "Class AmpC genes" is wrong. It should be "Class C beta-lactamase" or "AmpC gene". In this case, "AmpC gene" is better.

Is the work clearly and accurately presented and does it cite the current literature?
Partly

Is the study design appropriate and is the work technically sound?
Partly

Are sufficient details of methods and analysis provided to allow replication by others?
Yes

If applicable, is the statistical analysis and its interpretation appropriate?
Partly

Are all the source data underlying the results available to ensure full reproducibility?
Partly

Are the conclusions drawn adequately supported by the results?
Partly

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** microbiology, public health

I confirm that I have read this submission and believe that I have an appropriate level of expertise to state that I do not consider it to be of an acceptable scientific standard, for reasons outlined above.

**Author Response 06 Sep 2020**

Dina Naser, Central Laboratory, Khartoum, Sudan

- Classification of \texttt{bla}_{TEM}, \texttt{bla}_{SHV}, \texttt{bla}_{CTXM-1}, \texttt{bla}_{VEB} and \texttt{bla}_{OXA-1} changed from ESBLs to β-lactamases enzymes generally, they named in the draft as individual genes and classified as \texttt{β-lactamases} group.

This change applied in the whole draft including tables and figures, even the title changed to “\texttt{β-lactamases (bla}_{TEM}, \texttt{bla}_{SHV}, \texttt{bla}_{CTXM-1}, \texttt{bla}_{VEB}, \texttt{bla}_{OXA-1}) and class C \texttt{β-lactamases gene frequency in Pseudomonas aeruginosa} isolated from various clinical specimens in Khartoum State, Sudan: a cross sectional study”

- In abstract: The sample size mentioned as the confirmed 80 \textit{P. aeruginosa} isolates, the remaining 41 isolate other than \textit{P. aeruginosa} deleted.
- All “\textit{Ps. aeruginosa}” in the text changed to “\textit{P. aeruginosa}” as formal abbreviation.
- “\textit{Amoxyclav}” in the text changed to “\textit{amoxicillin/clavulanate}”
- “\texttt{Class AmpC genes}” in figure 5 changed to “\texttt{Class C β-lactamases}”
- “\texttt{ESBLs}” changed to “\texttt{β-lactamases}” in figure 3 and figure 5.

**Competing Interests:** No competing interests were disclosed.
The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage
