**How to cite this article:** Younis G, Awad A, Mohamed N (2017) Phenotypic and genotypic characterization of antimicrobial susceptibility of avian pathogenic *Escherichia coli* isolated from broiler chickens, *Veterinary World*, 10(10): 1167-1172.

**Abstract**

**Aim:** Avian pathogenic *Escherichia coli* (APEC) is pathogenic strains of *E. coli* that are responsible for one of the most common bacterial diseases affecting poultry worldwide. This study was designed to determine the occurrence, antibiotic resistance profile, and antibiotic resistance genes of *E. coli* isolated from diseased and freshly dead broilers.

**Materials and Methods:** In that context, a total of 200 broilers samples were examined by standard microbiological techniques for isolation of *E. coli*, and tested for their antimicrobial susceptibility against 15 antimicrobial agents using disc diffusion method. In addition, *E. coli* isolates were screened by multiplex polymerase chain reaction for detection of a number of resistance genes including *aadA* gene encodes streptomycin/neomycin, *tetA* encodes resistance to tetracycline, *sul1* encodes sulfonamides, and *β-lactamase* encoding genes (*bla*<sub>TEM</sub> and *bla*<sub>SIV</sub>).

**Results:** A total of 73 (36.5%) isolates were biochemically identified as *E. coli* strains. O78, O2, and O1 are the most prevalent serotypes detected. *E. coli* displayed a high resistance against penicillin (100%), followed by cefepime (95.8%) and a low resistance to norfloxacin (36.9%), and chloramphenicol (30%). Depending on the results of PCR, *sul1* gene was the most predominant antibiotic resistant gene (87%) followed by *bla*<sub>TEM</sub> (78%), *tetA* genes (60%), and *aadA* (54%). However, *bla*<sub>SIV</sub> had the lowest prevalence (23%).

**Conclusion:** The obtained results demonstrated the importance of studies on APEC and antibiotic resistance genes in our region which associated with intensive poultry industry, aiming to acquire preventive measures to minimize losses due to APEC and associated multidrug-resistance and resistance genes that of high significance to the rational use of antibiotics in clinical and public health.

**Keywords:** antimicrobial resistance, broilers, *Escherichia coli*, multiplex polymerase chain reaction, resistant genes.

**Introduction**

Avian pathogenic *Escherichia coli* (APEC) is a subgroup of extraintestinal pathogenic *E. coli*, enters through different routes including genital and respiratory tracts and causes various extraintestinal diseases collectively known as colibacillosis in chickens, which are responsible for high economic losses in the chicken industry [1]. The pathogenicity of APEC allows certain intestinal commensal *E. coli* to become APEC [2]. APEC belongs mostly to the serotypes O1, O2, and O78 or is often nontypable. APEC is also suspected to be a potential zoonotic risk for human [3].

Treatment of diseases caused by *E. coli* usually necessitates antimicrobial chemotherapy. The decision of using antimicrobial therapy based on the microorganism susceptibility and the drug pharmacokinetics for obtaining the required therapeutic concentration at the site of infection and therefore clinical efficacy [4]. Therefore, veterinarians have a restricted choice of antimicrobial agents to use it in the poultry industry, due to problems of multidrug-resistance (MDR) and human health hazard. Moreover, the constant misuse of antimicrobials led to increasing rate of antibiotic resistance [5]. Antibiotic resistance is a major problem that threatens human and animal health especially in underdeveloped and developing countries where antibiotics are used without control for prophylaxis and treatment of human and animal illnesses [6]. *E. coli* present in both human and animals possess resistance to several classes of antibiotics such as aminoglycosides, penicillin, streptomycin, cephalosporins, sulfonamides, tetracycline, and quinolones [7].

Many drug-resistant strains and genes can be transmitted and disseminated between animal and human pathogens, which not only increases the difficulty in treating animal diseases but also threatens the human health [8]. Therefore, the main goal of this study was to, determine the antibiotic resistance profile of APEC isolates and to detect their associated antibiotic resistance genes.
Materials and Methods

Ethical approval
There is no ethical approval necessary.

Samples collection
In this study, a total of 200 chicken visceral organs (liver, lungs, heart, spleen) and intestinal contents were collected randomly from diseased and freshly dead chicken broilers from different poultry farms located in the district of Mansoura City, Egypt. The chickens were ranged from 35 to 50 days old and showed different forms of diarrhea. The predominant lesions revealed in postmortem examination were ascites, pericarditis, splenitis, perirehepatitis, airsaccitis, and peritonitis. Using sterile scissors and tissue forceps, the visceral organs from each bird were collected separately and put in a polyethylene bag and transferred immediately in an ice tank to the laboratory for bacteriological analysis.

Bacteriological examination
From each chicken visceral organ, 2 g was directly inoculated in MacConkey broth and incubated for 18 h at 37°C. Then, a loopful from the previously inoculated broth was streaked onto MacConkey agar (Oxoid) plates for 24 h at 37°C. Rose pink colonies were picked up and streaked onto Eosin Methylen Blue (Oxoid) and incubated overnight at 37°C. The identification of E. coli isolates depends on the colonies morphological characters, and biochemical tests results following Ewing [9]. Further identification of E. coli isolates was done using commercial biochemical test kits (bioMerieux API, France).

Serotyping
Serological identification of E. coli isolates was done using rapid diagnostic E. coli antisera sets (Denka Seiken Co., Japan) according to Kok et al. [10] at the Department of Food Hygiene Control, University of Benha, Egypt.

Antimicrobial sensitivity testing
It was performed by disc diffusion method using Muller-Hinton agar using 15 antibiotic disc belongs to seven different antimicrobial classes including sulfamethoxazole (100 µg/disk), levofloxacin (5 µg/disk), chloramphenicol (30 µg/disk), norfloxacin (10 µg/disk), tetracycline (30 µg/disk), streptomycin (10 µg/disk), cefoxitin (30 µg/disk), ampicillin/sulbactam (10 µg/disk), neomycin (30 µg/disk), doxycycline (30 µg/disk), cefepime (30 µg/disk), cefotaxime (30 µg/disk), penicillin (10 µg/disk), amoxicillin (10 µg/disk), and nalidixic acid (30 µg/disk). Interpretation of the results was done following Clinical and Laboratory Standards Institute Guidelines [11].

DNA extraction
DNA was extracted according to Ramadan et al. [12] briefly; three presumptive E. coli colonies were inoculated into 3 ml trypticase soy broth and incubated for 18 h at 37°C. 1 ml of the previously inoculated broth was centrifuged at 8,000 g for 2 min. The sediment was washed with DNase/RNase-free water and heated at 95°C for 15 min; the supernatants were used as DNA template.

Detecting antimicrobial resistance genes by multiplex PCR
Multiplex PCR assay was done targeting five antibiotic resistance genes (blaTEM, blasul, TetA(A), AadA2, and sull) of APEC isolates. Primers used for multiplex PCR are as per the previously reported researchers [13-16]. PCR was performed in a total volume of 50 µL consisting of 25 µL of 2X PCR Master Mix (Promega, Madison, USA), 1 µL of each primer (Metabion, Germany), and 6 µL DNA templates. After an initial denaturation at 94°C for 5 min, 35 amplification cycles consisting of denaturation at 94°C for 30 s, annealing at 54°C for 45 s, and extension at 72°C for 45 s per kbp were performed, followed by a final extension at 72°C for 10 min. Amplified genes were separated by electrophoresis in a 1.5% agarose gel. The separated PCR products were visualized under ultraviolet light and photographed.

Results
Out of 200 examined specimens, E. coli was identified in 36.5% (73/200) of the total examined samples based on morphological and biochemical characteristics. The recovery rate of E. coli from different chicken samples was 28.76%, 27.39%, 23.28%, 15.06%, and 5.46% form lungs, spleen, heart, liver, and intestinal contents, respectively (Table-1). E. coli isolates were serotyped into 26 serotypes including O1, O2, O78, O126, O153, O114, O91, O121, O44, O63, O158, O171, O146, O124, O15, O8, O145, O117, O166, O128, O111, O55, O119, O159, O6, and O126 (Table-2). O78, O1, and O2 were the most prevalent serotypes with an incidence of 17.8%, 9.5%, and 9.5%, respectively.

Phenotypically, the recovered E. coli strains were tested for their antimicrobial resistance against 15 antimicrobial agents (Table-3). Resistance was most frequently detected against penicillin (100%) followed by amoxicillin (94.5%), cefpime (95.8%), cefoxitin (90.4%), cefotaxime (76.7%), neomycin (89%), sulfamethoxazole (90.4%), streptomycin (73.9%), doxycycline (69.8%), tetracycline (53.4%), nalidixic acid (49.3%), ampicillin/sulbactam (46.5%), leovofloxacin (42.4%), and to lesser extents chloramphenicol (30%), gentamicin (26.9%), and sulfamethoxazole (14.1%).

Table-1: Number of strains of avian pathogenic E. coli isolated from different samples.

| Organs                  | Number of isolated strains | n=73 (%) |
|-------------------------|----------------------------|----------|
| Lungs                   | 21 (28.76)                 |          |
| Liver                   | 11 (15.06)                 |          |
| Spleen                  | 20 (27.39)                 |          |
| Intestinal contents     | 4 (5.47)                   |          |
| Heart                   | 17 (23.28)                 |          |

E. coli = Escherichia coli
Veterinary World, EISSN: 2231-0916 1169

Available at www.veterinaryworld.org/Vol.10/October-2017/3.pdf

and norfloxacin (36.9%). All E. coli isolates displayed a MDR to antimicrobial agents (Table-4).

Multiplex PCR was used for detection of antibiotic resistance genes including bla_$\text{TEM}$, bla_$\text{SHV}$, aadA, tetA, and sulI (Figure-1). The recovery rate of these antibiotic resistance genes was 78%, 23%, 54%, 60%, and 87%, respectively. The sulI gene was the most prevalence gene (87%). In contrast, bla_$\text{SHV}$ had the lowest prevalence (23%) as shown in Table-4.

**Discussion**

E. coli is normally inhabitant the intestinal tract of poultry, but specific strains known as APEC have specific virulence factors and are able to cause avian colibacillosis. This disease is a major problem in poultry industry, as it causes high economic losses. Among 200 tested chicken samples, 73 (36.5%) E. coli isolates were recovered. These findings were nearly similar to the findings of Momtaz and Jamshidi [17]. On the other hand, Kiliç et al. [18] recorded a higher recovery rate (48%) of E. coli our total of 100 examined chicken samples. In Egypt, 49 (20%) E. coli strains out of 242 samples were isolated [19], which is relatively lower than our findings.

Table 2: Serogroups of avian pathogenic E. coli.

| Number of strains (n=73) | Type of samples | Serodiagnosis | Percentages |
|--------------------------|-----------------|---------------|-------------|
| 13                       | Lungs (4), spleen (4), heart (3), intestinal content, liver | O78 | 17.8 |
| 7                        | Lungs (2), spleen (2), heart, liver, intestinal content | O2:H6 | 9.5 |
| 7                        | Lungs (2), heart (3), spleen (2) | O1:H7 | 9.5 |
| 4                        | Heart (2), lungs, liver | O91:H21 | 5.4 |
| 4                        | Spleen, heart, lungs (2) | O8:H21 | 5.4 |
| 3                        | Spleen, lungs, liver | O114:H4 | 4 |
| 3                        | Lungs (2), heart | O126:H21 | 4 |
| 3                        | Heart, spleen, lungs | O26:H11 | 4 |
| 3                        | Spleen, liver, lungs | O145 | 4 |
| 3                        | Spleen, liver, heart | O44:H18 | 4 |
| 2                        | Intestinal contents, liver | O166 | 2.7 |
| 2                        | Lungs, heart | O117:H7 | 2.7 |
| 2                        | Intestinal contents, lungs | O55:H7 | 2.7 |
| 2                        | Liver (2) | O111:H2 | 2.7 |
| 2                        | Heart, spleen | O124 | 2.7 |
| 2                        | Spleen, heart | O158 | 2.7 |
| 2                        | Lungs, heart | O128:H2 | 2.7 |
| 1                        | Lungs | O153:H2 | 1.3 |
| 1                        | Liver | O119:H6 | 1.3 |
| 1                        | Spleen | O63 | 1.3 |
| 1                        | Spleen | O15:H2 | 1.3 |
| 1                        | Lungs | O159:H21 | 1.3 |
| 1                        | Spleen | O171:H2 | 1.3 |
| 1                        | Spleen | O146:H21 | 1.3 |
| 1                        | Lungs | O6:H4 | 1.3 |
| 1                        | Liver | O121:H7 | 1.3 |

E. coli=Escherichia coli

Figure 1: Agarose gel electrophoresis of multiplex PCR showing amplification of five antimicrobial resistance genes, $\text{bla}_{\text{TEM}}$ at 516 bp, sulI at 433 bp $\text{aadA}$ at 622 bp, tetA at 576 bp and $\text{bla}_{\text{SHV}}$ at 392 bp, Lane L: DNA molecular size marker (1000 bp), Lane Neg: Negative control, Lane Pos: Positive control.
could be typed, the most prevalent serogroups were O78, O2 and O1 with a prevalence of 17.8%, 9.5%, and 9.5%, respectively. In many studies conducted in Egypt, nearly the same serotypes with a predominance of O78 have been identified [12,23,24].

Antimicrobial agents are used in the prevention and treatment of infections and can also use as growth promoting agents in animals. Under the pressure of antibiotic selection, MDR bacteria have been aroused. In this study, E. coli showed a high rate of resistance to most antimicrobials tested. 100% of the tested E. coli isolates showed resistance against penicillin, 95.8% to cefepime and 94.5% to amoxicillin followed by considerable resistance to the rest of the examined agents. Most of these antimicrobials are regularly used as growth promoters or as prophylactic agents in the poultry industry in Egypt [25,26] and concurred with the previous reports [27-32].

Many studies have been reported the presence of antibiotic resistance genes in APEC strains [33]. The resistance genes mediated by plasmid can make the resistance prevail among various bacteria that lead to acquiring resistance genes without difficulty and produce MDR [34,35].

Phenotypic multi-resistance of E. coli isolates to aminoglycoside, β-lactams, tetracycline, and sulfonamides antibiotics could be attributed to the presence of aada, blaTEM tetA(A), and sul1 resistance genes, respectively, among the tested isolates. Regarding the distribution of these antibiotic resistance genes among E. coli isolates, sul1 was detected in 64 (87%) isolates and blaTEM identified in 57 (78%) isolates meanwhile tetA gene was identified in 44 (60%) isolates, 40 (54%) isolates were harbored aada, and 17 (23.28%) isolates were carried blaSHV. These findings agree with Ammar et al. [19] who found that blaTEM and sul1 genes had the highest prevalence among the tested antibiotic resist genes which have being amplified in all tested isolates (100%). In addition, blaTEM was detected in most of β-lactams resistance strains, similar results were reported by Ali [36]. In contrast to our results, a relatively higher prevalence of blaSHV was previously recorded in Spain (88%) [13] and Egypt (79%) [37]. These results are signifying that the results of antibiotic disc diffusion test actually agreed with the results of PCR for detection of the relevant antibiotic resistance genes.

The risk of spreading antibiotic resistance genes to humans should be considered when there is contamination of animal products, especially chickens, by bacterial strains resistant to most of antibiotics [38]. Recently, many of extended-spectrum beta-lactamases (ESBL) producing E. coli have become a worldwide issue. The ESBL-positive E. coli strains are highly resistant to a wide range of antibiotics. Controlling such strains with usually used antibiotics is ineffective; recently, there are few antibacterial alternatives that remain effective against these MDR pathogens [39].

**Conclusion**

It is very important to control APEC because it represents a grave danger to poultry and is a potential source of transferring MDR genes to human-specific E. coli or other bacteria such as Staphylococcus aureus and Shigella strains. The fact that this pathogen is naturally present in daily consumed food should be considered as a serious public health and food biosafety.

**Authors’ Contributions**

GY design the study shared in data analysis and revised the manuscript. AA and NM shared in samples collection, performing the tests, manuscript writing...
and data analysis. All authors read and approved the final manuscript.
