ABSTRACT

Introduction and Aim: Immobilization of enzyme on silver nanoparticles (AgNPs) is one way to improve their stability and activity and can be reused for large-scale applications. The present study was aimed to evaluate and characterize the trypsin enzyme immobilized on biogenically synthesized silver nanoparticles.

Materials and Methods: Immobilization of trypsin enzyme was optimized with time and varying concentration of silver nanoparticles, which were green synthesized using avocado seed extracts. The residual activity of trypsin enzyme after immobilization was estimated. The reusability and temperature stability of the immobilized enzyme were studied.

Results: The immobilized enzyme showed maximum activity of 1006.0 U during the time duration of 18 hr of incubation with AgNPs. Reusability of immobilized enzyme in avocado AgNPs was assessed under optimal conditions, the activity of immobilized enzyme was loss after 5 repeated cycles. The enzyme captured on AgNPs was released in the presence of anionic detergent. Temperature stability was assessed for immobilized enzyme on AgNPs and the immobilized enzyme was stable up to 55°C and later it loss their activity.

Conclusion: The study reports a feasible method of enzyme immobilization on biogenically synthesized silver nanoparticles. The enzyme immobilized on silver nanoparticles is mainly through non-covalent forces. Further studies are required to improve the reusability of enzyme.

Keywords: Silver nanoparticles; enzyme immobilization; trypsin; temperature stability; reusability; detergent.

INTRODUCTION

Enzymes are biocatalysts, involved in many biochemical reactions. They are universally present in plants and animals. Enzymes have extensive applications in health care, pharmaceuticals, leather, food and detergent industries (1-3). However, the use of enzyme in industrial applications are often set back due to some undesirable characteristics like, lack of shelf life, long-term operational stability at varying temperature, ionic strength and pH conditions, and recovery & reusability. One strategy to overcome these problems is immobilization of enzymes on appropriate matrices.

Enzyme immobilization is used for enhancing the stability and reusability in aqueous media (4) and more recently in non-aqueous media (5, 6). Enzyme immobilization is advantageous when the intention of use of enzymes is in commercial and industrial set ups by offering high temperature stability and, hassle free downstream process and cost effective (7). In 1916 invertase enzyme was immobilized on a solid matrix, such as charcoal or an aluminum hydroxide (4) and demonstrated that activity of invertase enzyme was not hampered when it is adsorbed. This aspect led to the development of currently available enzyme immobilization techniques (8-10). The reaction catalysis of immobilised enzyme is maximum due to increase in binding capacity and thus becomes cost effective (11).

Free enzyme is relatively unstable when compared to immobilised counterpart. This is because the structure of the free enzyme determines the function and rate of reaction of the enzyme. In case of an immobilized enzyme the stability is determined by factors like nature of interaction with the matrix or carrier, stereochimistry of binding, and the microenvironmnet of the immobilized enzyme, the chemical and physical structure of the carrier, and the conditions under which the enzyme molecules were immobilized (12).

The choice of support matrix and designing the carrier are very important factors to be considered during enzyme immobilization. In recent years, nanostructured materials have taken their place as matrix for enzyme immobilization. Nanostructures based on silica, carbon nanotubes and metal nanoparticles silver, copper, zinc and gold nanoparticles are attractive matrixes for immobilization.

Nanoparticles as a matrix for enzyme immobilization Nanoparticles are very efficient support materials for enzyme immobilization, because of their high specific surface area, mass transfer resistance, and effective enzyme loading capacity (13-16). Moreover, the enzyme bound nanoparticles show Brownian movement, when dispersed in aqueous
solutions showing that the enzymatic activities are comparatively better than that of the unbound enzyme (17). Various reviews on immobilization of enzymes on different types of nanoparticles (metal nanoparticles, metal oxide nanoparticles, magnetic nanoparticles, porous and polymeric nanoparticles etc.) have been reported earlier (18-20).

By using gold (Au) and silver (Ag) nanoparticles, enzymatic immobilization are studied using either as whole cells or isolated enzymes, which include lysozyme (21), glucose oxidase (22), and aminopeptidase (23), as well as alcohol dehydrogenase (24).

Lee et al., used amino-functionalized silica-coated magnetic nanoparticles to immobilize trypsin, they applied a pressure-assisted digestion for analysis, and more number of proteins was identified in comparison with the experiment with free trypsin (25).

In this study, optimization and characterization of trypsin enzyme immobilized on biogenically synthesized silver nanoparticles is carried. Further, the reusability temperature stability of bound enzyme is studied.

MATERIALS AND METHODS

Trypsin from bovine pancreas, silver nitrate (AgNO3) and sodium dodecyl sulphate (SDS) was purchased from Sigma Aldrich chemicals. All other reagents were of analytical grade.

Methods

Synthesis of silver nanoparticles

Silver nanoparticles are synthesized as described in Sneharani et al., (26).

Immobilization of trypsin enzyme

Time dependent immobilization

The immobilization of trypsin enzyme on AgNPs for different time (0, 1, 5, 10, 15, 18, and 21 hr) was carried out by keeping 100 µL of trypsin solution (1µg/µL) in 1.5 mL tube containing 100 µL of concentrated AgNPs. The volume was made up to 500 µL using distilled water, mix thoroughly and kept on Rotospin at constant speed 25 rpm at 6-8°C.

Optimization of different concentration of trypsin on immobilization

Varying concentration of trypsin (100-500 µg) were added to tube containing AgNPs and kept for incubation for 18hr. After incubation the reaction mixture was centrifuged at 14,500 rpm for 30 min. The supernatant contains unbound enzyme and the pellets are AgNPs bound with enzyme. To the pellet 50 µL distilled water is added and used as the source of immobilized enzyme.

Fig. 1: Effect of different concentration of AgNPs on enzyme immobilization

Enzyme assays for trypsin

The activity of free and immobilized trypsin was detected by the method of Erlanger et al., (1961) with slight modification. Proteolytic activity was examined by measuring the hydrolysis of peptidyl-pNAs (BAPNA). The rate of enzymatic hydrolysis of peptidyl-pNAs substrates was measured using a colorimeter at 450nm.

Reusability of immobilized enzyme

The reusability of the immobilized trypsin was evaluated for BAPNA hydrolysis at 37°C. After each cycle of enzyme assay, the immobilized trypsin was collected by centrifugation, washed several times with distilled water and used to check the enzyme activity. The immobilized trypsin on first use is assigned to have a relative activity of 100 %.

Fig. 2: The activity of immobilized enzyme in presence of different concentration of trypsin

Thermal stability of immobilized enzyme

The thermal stability of trypsin in its free and immobilized states was evaluated by measuring the residual activity at different temperature in tris-HCl buffer (pH 8.2 50 mmol/L, BAPNA). The residual trypsin activity was measured at varying periods of temperature (4°C, 25°C, 37°C, 55°C, 65°C, and 75°C). The free and immobilized trypsin without incubation was assigned a relative activity of 100 %.

Fig. 3: Effect of different time interval for enzyme immobilization
Effect of detergent on free and immobilized enzyme
Enzyme activity of unbound and immobilized enzyme in presence of anionic detergent (sodium dodecyl sulphate) was checked by adding varying concentration of SDS (0.1-0.5 %). The enzyme activity is measured at 450 nm in colorimeter.

RESULTS AND DISCUSSION

Optimization of trypsin immobilization on silver nanoparticles

Fig. 1 shows the optimization of percent AgNPs for immobilizing the trypsin enzyme. Percent concentration ranging from 10 to 50 (w/v) was incubated with trypsin. At the end of incubation period, the AgNPs bound to enzyme were collected and the activity of enzyme was checked. A linear increase in the activity of enzyme was observed with increase in concentration of AgNPs from 10 to 50 %.
This is due to the increase in the available surface area for the attachment of enzyme on AgNPs. Likewise, to optimise the trypsin concentration for optimal binding varying the concentration of trypsin (100 to 500 µg) was incubated with 50 % concentration of AgNPs. Fig. 2 shows the activity of immobilized enzyme in presence of different concentration of trypsin on AgNPs. At 100µg of trypsin, maximum activity of enzyme was seen. At this concentration all the available surface on AgNPs is occupied with trypsin.

Fig. 4: Reusability of immobilized enzyme

Fig. 5: Effect of different concentration of detergent on activity of enzyme

Effect of temperature on immobilized enzyme

Due to sensitivity at higher temperatures, enzymes are heat labile and immobilizing enzymes often overcome this. The thermal stability of the immobilized trypsin was measured in comparison with that of free trypsin. Fig. 6 shows the result of thermal stability of the trypsin immobilized on AgNPs. The activity of trypsin immobilized on AgNPs was comparatively stable when compared with unbound enzyme at different temperature. The unbound trypsin lost almost all of its activity at 60°C.
after 1 hour of incubation, whereas the immobilized trypsin retained more than 25% of its residual activity at the end of 1h of incubation. The enzymes immobilized on AgNPs are more stable than the unbound enzyme. The thermal stability of the immobilized trypsin is enhanced at high temperature. This is due to the protection of any conformational denaturation of the enzyme at higher temperatures, making it more heat-resistant than in unbound form.

CONCLUSION

Using the immobilization technique, the enzyme activity and stability can be enhanced. In this study, metal nanoparticles were used to immobilize the enzyme. Small size and large surface area of the nanoparticles favours enzyme immobilization and stabilization. In this study, we observed increase in the stability and activity of enzymes increases when immobilized on such materials.
