Abstract

Primary signet-ring cell carcinoma of cervix is extremely rare in the literature. Usually Signet-Ring Cell Carcinomas (SRCCs) of the cervix are metastatic from a primary gastric, colonic, ovarian, or breast carcinoma. A 48-year-old woman was referred to our Department due to persistent abnormal vaginal bleeding during the last two months. Gynecologic examination revealed cervical tumor. Biopsy revealed a signet ring cell type of mucinous adenocarcinoma. Extensive systemic examination reveals liver metastases confirmed. The patient was treated with palliative chemotherapy. The prognosis of primary signet ring cell adenocarcinoma of the uterine cervix is still unclear because of the rare incidence of cases. In this report we reviewed the literature to identify the clinical, pathological and immunohistochemical features of this rare malignancy.

Keywords: Cervix neoplasms; Signet ring cell carcinoma; Immunohistochemical; Adenocarcinoma

Introduction

Carcinoma of the uterine cervix is the most common malignancy in female genital tract in developing countries [1]. The current frequency of cervical adenocarcinoma is 10% to 25% of all the cervical carcinomas in developed countries and most of them are endocervical type [1].

Mucinous adenocarcinoma of the cervix was subdivided into 5 subtypes: endocervical, intestinal, signet-ring cell, minimal deviation, and villoglandular [2]. Adenocarcinomas with signet ring cell are mostly metastatic from gastric, breast, colonic or ovarian carcinomas and primary tumor is extremely rare [1-3]. The prognosis of primary signet-ring cell carcinoma (PSRCCs) of the cervix is not well known as a result of the small number of case reports.

We describe a case of primary adenocarcinoma of the uterine cervix, signet-cell type. In addition, we reviewed all reported cases in the literature, to the best of our knowledge.

Case Report

A 48-year-old woman, gravida seven, para five, aborta 2, married at the age of 18 not yet menopause and her medical and family history was unremarkable. She was a heavy smoker (tow pack/day) for 10 years, no alcohol, and used oral contraceptives on and off for about 10 years. She was admitted to our hospital for spontaneous and intermittent abnormal vaginal bleeding which had been present during the last two months. Gynecological examination revealed diffuse enlargement of the cervix which had been replaced by an exophytic ulcerated, reddish lesion with distal parametrial infiltration. We performed a cervical biopsy and endocervical curettage. Microscopic examination shows cells with eccentric hyperchromatic nuclei and large mucin filled cytoplasmic vacuoles growing in clusters and in nests or columns within pools of extracellular mucin (signet-ring cells) (Figures 1-3). An extensive immunohistochemical evaluation of the biopsies was performed. The neoplastic cells were diffusely positive for p16, Cytokeratin 7 and carcinoembryonic antigen, whereas cytokeratin 20, chromogranin A, synaptophysin, vimentin and hormonal (estrogens and progesterone) receptors were negative. Abdominal pelvic magnetic resonance imaging (MRI) demonstrated about 53 mm × 36 mm size mass in the endocervical canal. Chest X-ray, gastroscopy, colonoscopy

total, oral endoscopy and mammography, failed to show any other primary tumor. We practiced an abdominal pelvic scanner which revealed lombo-aortic adenopathy as well as hepatic metastasis biopsy-confirmed. All these results were consistent with a primary PSRCC FIGO (2009) cervical tumor stage IVB. The patient was referred to medical oncology for palliative treatment. Cisplatin has been indicated at doses 50 mg/m² once every 3 weeks. But, his health condition had severely and rapidly deteriorated, therefore she doesn’t receive chemotherapy. She was deceased three months later.

Discussion

The most common adenocarcinoma of the uterine cervix is the usual endocervical type [1]. Mucinous adenocarcinoma of signet-ring cell type is very rare [4,5]. Usually, signet-ring cell differentiation found in cervical carcinoma strongly suggests a metastatic carcinoma usually from a gastro-intestinal, appendicular, mammary or ovarian origin.

Localized disease to the cervix and eight patients had advanced tumors. Signet ring cell carcinoma of the cervix is not well known [1]. Ten patients had also supports this opinion [7]. The prognosis of primary signet-ring cell carcinoma at the moment of the diagnosis and later in the course of the disease, the absence of extra genital pathology, demonstrated by investigations previous published examples of the PCSRCC, the primary cervical origin. No positive case of PCSRCC was reported [5]. However, positivity for mammoglobin favors a mammary origin. The presence of p16 immunohistochemical staining [13]. In our case, as well as in some previous published cases of the PCSRCC, the primary cervical origin. No positive case of PCSRCC was reported [5]. Oestrogen and progesterone receptors have been tested in only 4 previous cases [2,3,9]. But it has been suggested that primary cervical adenocarcinoma [16]. A resistance to radiotherapy and/ or chemotherapy was reported [3-5,7,9]. However, extended survival in a low-stage tumor was reported in two cases [8,15]. We have not a clear consensus; the treatment of this rare tumor joins the treatment recommendations for uterine cervix adenocarcinoma [16]. To the best of our knowledge, only 20 cases (included our case) have been reported in the literature (Table 1). In most cases of previous reports, the signet-ring cell component is included in a part of histological types [6]. All cases were admitted as primary only after a careful combined clinical, endoscopic and radiological investigation to rule out the presence of an occult primary site. Immunohistochemical and molecular studies have often provided important information for differential diagnosis. Several immunohistochemical markers have been used in the literature to support the primary origin of cervical cancer, although their usefulness is debatable. Indeed, primary cervical carcinoma can express colorectal antigens such as ACE, caudal-related homeobox (CDX-2) and cytokeratin 20 (CK20) [7,8]. Moreover, simultaneous positivity to ACE and keratin 7 do not differentiate simulate metastatic signet-ring cell carcinoma. Clinical investigations and immunohistological studies are essentials for differential diagnosis [4,8].

CKCK: Cytokeratin; MUC: Mucin; TTF: Thyroid Transcript Factor; GCDFP: Gross Cystic Disease Fluid Protein; ER: Estrogen Receptor; PR: Progesteron Receptor; NA: Not Available; Sx: Surgery; Rx: Radiation Therapy; DOD: Died of Disease; NED: Not Evidence of Disease; Mo: Months; Yrs: Years; Wks: Weeks; Chemo: Chemotherapy; CEA: Carcinembryonic Antigen; CDX-2: Caudal-Type Homebox 2; SMA: Smooth Muscle Actin; PGP: Protein Gene Product; TTF: Thyroid Transcript Factor 1; Pre-Chemo: Preoperative Chemotherapy

To the best of our knowledge, only 20 cases (included our case) of primary cervical carcinoma containing signet-ring cell morphology have been reported in the literature (Table 1). In most cases of previous reports, the signet-ring cell component is included in a part of histological types [6]. All cases were admitted as primary only after a careful combined clinical, endoscopic and radiological investigation to rule out the presence of an occult primary site. Immunohistochemical and molecular studies have often provided important information for differential diagnosis. Several immunohistochemical markers have been used in the literature to support the primary origin of cervical cancer, although their usefulness is debatable. Indeed, primary cervical carcinoma can express colorectal antigens such as ACE, caudal-related homeobox (CDX-2) and cytokeratin 20 (CK20) [7,8]. Moreover, simultaneous positivity to ACE and keratin 7 do not differentiate between PCSRCC and gastric or mammary metastatic malignancy [5]. However, positivity for mammoglobin favors a mammary origin. No positive case of PCSRCC was reported [5]. Oestrogen and progesterone receptors have been tested in only 4 previous cases [2,3,9] and these were present only in one example [10]. Neuroendocrine differentiations have been demonstrated in two cases [7,10] but these markers were negative in our case. Positivity of Human Papillomavirus (HPV) DNA using molecular analysis provides diagnostic evidence of primary signet-ring cell carcinoma of the cervix [4,5]. The presence of HPV 18 has been determined in five cases of primary signet-ring cell carcinoma of the cervix [4,7,11-13]. No case was reported with negative p16 immunohistochemical staining [13]. In our case, as well as in some previous published examples of the PCSRCC, the primary cervical origin was supported by the presence of P16 Immunoreactivity [12,13], which may be considered a surrogate marker for HPV infection [4]. The absence of extra genital pathology, demonstrated by investigations at the moment of the diagnosis and later in the course of the disease, also supports this opinion [7]. The prognosis of primary signet-ring cell carcinoma of the cervix is not well known [1]. Ten patients had localized disease to the cervix and eight patients had advanced tumors [2,4,5,7,10-14], in one cases with stage IV, was expired shortly after 3 months [12]. However, extended survival in a low-stage tumor was reported in two cases [8,15]. We have not a clear consensus; the treatment of this rare tumor joins the treatment recommendations for uterine cervix adenocarcinoma [16]. A resistance to radiotherapy and/or chemotherapy was reported [3-5,7,9]. However, it has been suggested that advanced stage disease is particularly aggressive [4,7,12,14].

### Conclusion

Primary signet-ring cell carcinomas of the cervix are rare and associated with a poor outcome [17]. Prognosis seems to be related to the clinical stage [4,10]. Awareness of this entity is important as it simulate metastatic signet-ring cell carcinoma. Clinical investigations and immunohistological studies are essentials for differential diagnosis [4,8].
