Abstract.

This study introduces scientific concepts such as gravitational cells and gravitational strings. Gravitational cells and gravitational strings have been organically built into the concept of a gravitational field. This innovation has led to significant scientific results. These results include obtaining the formula for the gravitational constant, the formula for the electron mass, the formula for the mass of the hydrogen atom, the formula for the minimum distance of the action of the gravitational field, etc. All formulas were confirmed by experimental data. In this work, the Planck formula was successfully applied to the gravitational field. A distinctive feature of this study is the fact that most of the new formulas contain only fundamental physical constants (without introducing additional indicators and proportionality coefficients). In this work, the concept of a gravitational quantum is introduced and its value is determined. Also, a new physical constant was obtained - the mass of the gravitational cell of a black hole.

Keywords. Black hole, gravitational cell, gravitational string, gravitational quantum, gravitational constant formula, the proportion between the mass of the electron and the proton, electron mass formula, hydrogen atom mass formula, elementary charge, Schwarzschild radius formula, gravitational cell mass, the gravitational field, gravitational constant, vibrational velocity of a gravitational string, the formula for the vibrational velocity of a gravitational string, the minimum distance of action of gravitational forces, Casimir force.
Introduction.

This study envisages embedding into the concept of the gravitational field, such physical concepts as gravitational cells and gravitational ones. This will make it possible to move from general concepts of the gravitational interaction of bodies in space to a more detailed understanding of this physical process and to obtain confirmed scientific results.

Methods.

The gravitational field of any body cannot be considered separately without taking into account the interaction of this body with another body in space. In this case, the magnitude of the gravitational field depends not only on the amount of matter (mass), but also on the structure of the interacting bodies. This structure includes gravitational cells. These cells have a charge equal to two elementary charges $2q$ and a mass $m$. Each gravitational cell $m$ forms around itself in space a set of point gravitational fields $g_n$, the intensity of which depends on the distance $r_n$ to this point, that is, $g_n = \frac{2q}{r_n}$. These numerous point fields are up to a certain point latent potential fields and can manifest themselves only upon contact with the gravitational cells of other bodies. Therefore, when another body of mass $M_1$ (also consisting of a plurality of gravitational cells with a charge of $2q$) hits this area of space, a real gravitational field now appears at the point of contact of two cells:

$$g = \frac{k \cdot 2q \cdot k \cdot 2q}{r^2} = \frac{k^2 \cdot 4q^2}{r^2}.$$  
As a result, the field $g$ imparts the acceleration $g = \frac{k^2 \cdot 4q^2}{r^2}$ to the gravitational cell of the body $M_1$. Due to the fact that the body $M_1$
consists of a huge number of such cells with a charge of $2q$, and the dimensions of the body are much less than the distance $r$ between $M$ and $M_1$, then the whole body $M_1$ will experience an acceleration in this area of space equal to the magnitude of the acceleration of one gravitational cell, that is, $g = \frac{k^2 4q^2}{r^2}$. (This situation can be compared with the same accelerated motion of many absolutely identical charged particles in an electric field of a large electric charge).

Now let's move on to the basic formulas. A body of mass $M$ consists of a huge number of $n$ gravitational cells of mass $m$, where $n = \frac{M}{m}$. These cells together form a common gravitational field $E = g \cdot n$. As a result of all of the above, the formula for the gravitational field of a body with mass $M$ when it interacts with another mass $M_1$ looks like this:

$$E = g \cdot n = \frac{k^2 4q^2}{r^2} \frac{M}{m} \quad (1-1)$$

where $E$ is the gravitational field of the body $M$, m/s$^2$.

$g$ is the value of the field of one gravitational cell of the body $M$, m/s$^2$.

$m$ is the mass of the gravitational cell of the body $M$, kg.

$n$ is the number of gravity cells in the mass $M$.

$q$ is the value of elementary charges, where $q = 1,60217733 \cdot 10^{-19}$ Cl.

$k$ - coefficient of proportionality of charges, $\frac{m^{3/2}}{C \cdot s}$

The field interaction of two gravitational cells in space can be considered as an extended power string. The energy of such a gravitational string is $e = k^2 4q^2 J$. Hence the formula (1-1) will take the following form:
\[
E = k_{\text{conv.}} \frac{e}{r^2} \frac{M}{m} \quad (1-2)
\]

where \( e \) is the energy of the gravitational string between the cells, J.

\( k_{\text{conv.}} \) - coefficient for converting units of measurement, where \( k_{\text{conv.}} = 1 \text{ m / kg} \).

Note also that if in the formula (1-2) the expression \( k_{\text{conv.}} \frac{e}{r^2} \) is denoted as \( G \), then we get the familiar formula of the gravitational field: \( E = G \frac{M}{r^2} \).

To clearly understand the physics of the process, it is necessary first to consider the case of the gravitational interaction of two superdense masses, called black holes. So, we have two superdense masses \( M_0 \) and \( M_{01} \), located at a distance \( r \) from each other. These two masses are a homogeneous substance, consisting of many superdense cells with mass \( m_0 \) and a charge equal to the value of two elementary charges - \( 2q \). Such gravitational cells were formed after an extremely dense compression of matter, as a result of which molecules and atoms turned into identical gravitational cells, consisting of two opposite charges. (The mass of such a cell should be less than the total mass of a free proton and a free electron by \( \Delta m \) due to the release of energy during the compression of matter, where \( \Delta m = E/c^2 \)). The formula of the gravitational field \( E \) of a superdense body with mass \( M_0 \) in its interaction with another superdense body \( M_{01} \) looks like formula (1-2):

\[
E = k_{\text{conv.}} \frac{e_0}{r^2} \frac{M_0}{m_0} \quad (1-3)
\]

\( e_0 \) is the energy of the gravitational string between two cells, J.

\( m_0 \) is the mass of the gravitational cell, kg.
In expanded form, the formula (1-3) looks like this:

\[ E = k_{\text{conv.}} \frac{k_0^2 4q^2 M_0}{m_0} \]  

(1-4)

\( k_0 \) is the proportionality coefficient of the charges in the cell, where \( k_0 = 1 \)

(hence \( e_0 = 4q^2 = 1,026789 \cdot 10^{-37} \text{ J} \)).

\( q \) – elementary charge, \( 1,60217733 \cdot 10^{-19} \text{ Cl.} \)

Formula (1-4) shows that in a superdense state of matter, the proportionality coefficient of charges is \( k_0 = 1 \) (for comparison: when electric charges interact in a vacuum, \( K = 9 \cdot 10^9 \)). The reason for such a large discrepancy lies in the fact that the substance of the black hole is so strongly compressed that almost all lines of force of elementary charges are closed inside gravitational cells. And only an extremely small part of the lines of force goes out, creating a gravitational field in the outer space. As a result of this circumstance, the coefficient of proportionality of elementary charges outside the cell decreases to its minimum threshold, that is, exactly to 1. In this case, the main field, with the coefficient of proportionality \( K = 9 \cdot 10^9 \), remains closed between the elementary charges inside the gravitational cell and therefore does not manifest itself in any way.

In the formula (1-3), the expression \( k_{\text{conv.}} \frac{e_0}{m_0} \) shows the value of the gravitational constant, where \( G_0 = k_{\text{conv.}} \frac{e_0}{m_0} \) or \( G_0 = \frac{e_0}{m_0} \).

If we accept the condition that the gravitational constant in the black hole region \( G_0 = G = 6,6743 \cdot 10^{-11} \), then we get:
\[ m_0 = \frac{e_0}{G_0} = \frac{1.026789 \cdot 10^{-37}}{6.6743 \cdot 10^{-11}} = 1,538422 \cdot 10^{-27} \text{ kg} \ (1-5) \]

But such a result \( m_0 \) cannot be considered final, because the gravitational constant \( G_0 \) under extreme conditions of a black hole may have a different value. Therefore, for the sake of purity of the study, the obtained value \( m_0 = 1,538422 \cdot 10^{-27} \text{ kg} \) should be checked through another formula associated with the concept of "black hole". Such a test formula is the Schwarzschild radius formula.

\[ R = \frac{2G_0}{c^2} \cdot M \ (1-6) \]

where \( R \) is the gravitational radius of a black hole, \( m \), \( G_0 \) is the gravitational constant in the field of a black hole, \( M \) is the mass of a black hole, kg, \( c \) is the speed of light, m/s.

In this formula, the expression \( \frac{2G_0}{c^2} \) is of particular interest. This expression is equal to \( \frac{R}{M} \), measured in "m / kg" and is a specific indicator of "length" and "mass". When multiplying \( \frac{2G_0}{c^2} \) by the mass of the body \( M \), the gravitational radius of the black hole is determined. But in the one-dimensional space of a black hole, such a physical quantity as length does not exist, therefore the \( \frac{R}{M} \) index in "m / kg" should be perceived as the minimum structural unit of the black hole substance, that is, the mass of the gravitational cell \( m_0 \). It follows that \( m_0 = \frac{2G_0}{c^2} \). Taking into account the fact that according to f. (1-5) \( m_0 = \frac{e_0}{G_0} \), we get the following equation:

\[ \frac{2G_0}{c^2} = \frac{e_0}{G_0} \].
Let's solve this equation and get:

\[ G_0 = \sqrt{2} q c = 6.7927 \cdot 10^{-11} \quad (1-7) \]

\[ m_0 = \frac{\sqrt{8} q}{c} = 1.511593 \cdot 10^{-27} \text{ kg} \quad (1-8) \]

As you can see, the mass of the gravitational cell of the black hole is \( m_0 = 1.511593 \cdot 10^{-27} \text{ kg} \), and not \( 538422 \cdot 10^{-27} \text{ kg} \), as calculated above. But at the same time, these very close results, which were obtained in different ways, indicate the correctness of the hypothesis of gravitational cells. When choosing between two values of \( m_0 \), it will be more correct to dwell on the value obtained using the Schwarzschild formula, that is, \( m_0 = 1.511593 \cdot 10^{-27} \text{ kg} \). (This will be confirmed by calculations in this article when determining the mass of a hydrogen atom).

The discrepancy between \( G_0 = 6.7927 \cdot 10^{-11} \) and \( G = 6.6743 \cdot 10^{-11} \) is only 1.7%. This slight difference is due to structural changes in superdense gravity cells.

Now let us consider the gravitational interaction of an "ordinary" body of mass \( M \) with another "ordinary" mass \( M_1 \). The formula of the gravitational field \( E \) of the body \( M \) according to the basic formula (1-2) looks like this:

\[ E = k_{\text{conv.}} \frac{e_1}{r^2} \frac{M}{m} \quad (1-9) \]

\( e_1 \) is the energy of the gravitational string between the cells, where \( e_1 = 1.108293 \cdot 10^{-37} \text{ J} \).

\( k_{\text{conv.}} \) – coefficient for converting units of measurement, where \( k_{\text{conv.}} = 1 \text{ m/kg} \).
\( m \) is the mass of the "ordinary" gravitational cell, where \( m = 1,660539 \cdot 10^{-27} \) kg.

In expanded form, this formula looks like this:

\[
E = \frac{k_1^2 q^2}{r^2} \frac{M}{m} \tag{1-10}
\]

where \( k_1 \) is the proportionality coefficient of the charges of the gravitational cell, where \( k_1 = 1,038931, k_2 = 1,079378 \).

From here we obtain the classical formula of the gravitational field: \( E = G \frac{M}{r^2} \), where \( G = \frac{e_1}{m} = 6,6743 \cdot 10^{-11} \).

Let us now explain the quantities \( k_1 \) and \( m \). To do this, imagine that ordinary matter was formed from the superdense matter of a black hole. In this case, each superdense gravitational cell, due to the influx of energy \( E \), will increase its mass \( m_0 \) to mass \( m \) by the amount \( \Delta m \) (where \( \Delta m = E/c^2 \)). As a result, a plasma is formed from a superdense substance, from which gaseous, liquid and solid substances can then be formed. All four states of matter are neutral, that is, they have a total electric charge equal to zero. As a result of this circumstance, any "ordinary" substance can be represented as a huge set of gravitational cells. All four states of matter are neutral, that is, they have a total electric charge equal to zero. As a result of this circumstance, any "ordinary" substance can be represented as a huge set of gravitational cells. These cells consist of a proton and an electron with a total charge of \( 2q \), as well as of neutrons, which are also a pair of a proton and an electron with a total charge of \( 2q \). Thus, the mass of the gravitational cell
$m$ of any substance (plasma, gas, liquid or solid) with a high degree of accuracy will be equal to 1 Da or $m = 1,660539 \cdot 10^{-27}$ kg.

Under the conditions of the standard density of the substance, $k_1 = 1,038931$, that is, $k_1 > k_0 = 1$. This very small difference between $k_1$ and $k_0$ can be explained by the fact that, in contrast to the gravitational cell of a black hole, where elementary charges are absolutely tightly adjacent to each other, in an ordinary cell there is some ultramicroscopic distance between two elementary charges. As a result of this circumstance, a little more lines of force come out of an ordinary cell, as a result of which $k_1 > k_0$.

The gravitational interaction of an "ordinary" body of mass $M$ and a superdense body of mass $M_0$ is determined by the total value $e_1 = k_1^2 4q^2 = 1,108293 \cdot 10^{-37}$ J and different masses of gravitational cells $m = 1,660539 \cdot 10^{-27}$ kg and $m_0 = 1,511593 \cdot 10^{-27}$ kg.

Hence, we obtain the following formulas for the gravitational field:

The gravitational field of an "ordinary" body $M$:

$$E = k_{\text{conv.}} \frac{e_1}{r^2} \frac{M}{m} \left( k_{\text{conv.}} = 1 \text{ m/kg} \right) \text{ or } E = G \frac{M}{r^2}, \text{ where } G = 6,4242 \cdot 10^{-11}$$

The gravitational field of a superdense body $M_0$:

$$E = k_{\text{conv.}} \frac{e_1}{r^2} \frac{M_0}{m_0} \left( k_{\text{conv.}} = 1 \text{ m/kg} \right) \text{ or } E = G \frac{M_0}{r^2}, \text{ where } G = 7,0572 \cdot 10^{-11}$$

It should be noted that these $G$s are of secondary importance in this study, because they do not reflect the physical essence of the gravity process.
The inclusion of gravitational cells and gravitational strings in the concept of the gravitational field allowed other significant results to be obtained. Such results are obtaining a new formula and calculating the mass of a hydrogen atom using it (complete coincidence with the experimental mass of a hydrogen atom was obtained), as well as obtaining a formula and calculating the mass of an electron inside a substance.

Under the conditions of a black hole, when matter is maximally compressed, the gravitational field between two superdense gravitational cells contracts so much that it turns into a point gravitational quantum. In this situation, the gravitational field formula no longer works and Planck's formula works instead:

\[ e_0 = h \gamma \]  

(1-11)

where \( e_0 \) is the energy of the gravitational quantum of the black hole, \( e_0 = 1,026789 \cdot 10^{-37} \) J.

\( h \) is Planck's constant, \( 6,62607 \cdot 10^{-34} \) J \cdot s.

\( \gamma \) - frequency, where \( \frac{e_0}{h} = 1,549620 \cdot 10^{-4} \) s\(^{-1} \) (\( \gamma \) is constant and does not depend on the SI or CGSE measurement system).

The \( \gamma \) frequency is related to the proportion between the energy-mass of negative and positive charges in the gravitational quantum:

\[ \gamma = \frac{1}{4} \frac{2 e_{-e}}{2 e_{+p}} = \frac{1}{4} \frac{e_{-e}}{e_{+p}} \]  

(1-12)

\( e_{-e} \) is the value of the energy of the negative charge inside the cell, J.

\( e_{+p} \) - the value of the energy of the positive charge inside the cell, J.

Hence, for \( \gamma = \frac{e_0}{h} \), we obtain the formula:
\[
\frac{e_{-e}}{e_{+p}} = \frac{4e_0}{h} \quad (1-13)
\]

The definition of “energy-mass of negative and positive charge” was introduced because electrons and protons are not independent particles inside gravitational cells and gravitational quanta. The fraction 1/4 is explained by the fact that four charges are involved in the formation of a gravitational quantum, while only one charge in the form of an electron participates in the formation of an electromagnetic quantum. (The correctness of formulas (1-11) and (1-12) will be confirmed below by the coincidence of calculations by these formulas with experimental data.

Based on f. (1-11), (1-12) and taking into account that the total energy of the gravitational cell is \( m_0c^2 = e_{+p} + e_{-e} \), we obtain the formula for the energy of a negative charge inside a superdense cell:

\[
e_{-e} = \frac{4e_0 m_0c^2}{h + 4e_0} \quad (1-14)
\]

Taking into account that \( m_0 = \sqrt{8 \frac{q}{c}} \) and \( e_0 = 4q^2 \), we obtain the value \( e_{-e} \) through the formula with three fundamental constants:

\[
e_{-e} = \frac{32\sqrt{2} q^3 c}{(h + 16q^2)} = 8.415740 \cdot 10^{-14} \text{ kg} \quad (1-15)
\]

As you can see, \( e_{-e} \) almost coincided with the energy of a free electron, where \( e = 8.187110 \cdot 10^{-14} \text{ J} \). The discrepancy is 2.7%. (It should be noted that there should not be a complete coincidence here, because the negative charge inside the gravitational cell and the free electron are different physical quantities).
The energy value of the positive charge in the cell will be: 
\[ e_{+p} = m_0 c^2 - e_e = 1,511,593 \cdot 10^{-27} \cdot c^2 - 8,415,740 \cdot 10^{-14} = 13,577,104 \cdot 10^{-11} \text{ J}. \]

The ratio between the energies of elementary charges in a superdense cell is: 
\[ \frac{e_{-e}}{e_{+p}} = 4 e_0 \]

\[ \frac{e_{-e}}{h} = 6.19848 \cdot 10^{-4} \]

The body of a black hole consists of a huge set of such closely spaced superdense cells. Now let's consider the process of formation of hydrogen atoms from gravitational cells. For this, external energy must enter each cell. As a result of energy entering the cell, the positive charge in the cell \( e_{+p} = 13,577,104 \cdot 10^{-11} \text{ J} \) increases exactly by the value \( \Delta e_{+p} = 1,455,672 \cdot 10^{-11} \text{ J} \), that is, up to the value of the rest energy of the proton: 
\[ e_p = m_p c^2 = 1,672,6219 \cdot 10^{-27} \cdot c^2 = 15,032,776 \cdot 10^{-11} \text{ J}. \]

(More than this value, the positive charge in the cell cannot increase!). Thus, the total energy of the gravitational cell increases by \( \Delta e_{+p} \) and becomes equal to:
\[ e = e_{-e} + e_p = 8,415,740 \cdot 10^{-14} + 15,032,776 \cdot 10^{-11} = 15,041,191 \cdot 10^{-11} \text{ J} \]

As you can see, the calculated value \( e = 15,041,191 \cdot 10^{-11} \text{ J} \) almost absolutely coincided with the experimental value of the energy of the hydrogen atom, where \( e_h = 1,673,5575 \cdot 10^{-27} \cdot c^2 = 15,041,855 \cdot 10^{-11} \text{ J} \). The ultramicroscopic discrepancy of \( 6 \cdot 10^{-17} \text{ J} \) can be safely attributed to the permissible error of calculations. But at the same time, this very small discrepancy may be a consequence of the release of neutrino particles during the formation of a
hydrogen atom (here it is necessary to take into account that $e = 15,041191 \cdot 10^{-11} \text{J} > e_h = 15,041185 \cdot 10^{-11} \text{J}$, and not vice versa). Therefore, taking into account this probability, we write the result obtained by the following formula:

$$e_h = \frac{32\sqrt{2} q^3 c}{(h+16q^2)} + e_p - \sum e_v$$

(1-16)

where $e_h$ is the energy of a hydrogen atom, $15,041185 \cdot 10^{-11} \text{J}$.

$e_p$ is the rest energy of a proton, $15,032776 \cdot 10^{-11} \text{J}$.

$\sum e_v$ - total neutrino energy, $\sum e_v = 6 \cdot 10^{-17} \text{J}$.

$q, h, c$ - fundamental physical constants.

(It should be noted that after the formation of a hydrogen atom from a superdense cell, the ratio between the charge energies $\left(\frac{e-e}{e+p} = 6,19848 \cdot 10^{-4}\right)$ changes and becomes equal:

$$\frac{e-e}{e+p} = \frac{4 e}{h} = \frac{4 \cdot 1,108293 \cdot 10^{-37}}{h} = 6,6905 \cdot 10^{-4}$$

Taking into account that $E = mc^2$, we get the formula for the mass of a hydrogen atom:

$$m_h = \frac{32\sqrt{2} q^3}{c (h+16q^2)} + m_p - \sum m_v$$

(1-17)

where $m_h$ is the mass of a hydrogen atom, $1,6735575 \cdot 10^{-27} \text{kg}$.

$m_p$ is the mass of the proton, $1,6726219 \cdot 10^{-27} \text{kg}$.

$\sum m_v$ is the total mass of the neutrino, $\sum m_v = 7 \cdot 10^{-34} \text{kg}$.

$q, h, c$ - fundamental physical constants.

Considering that the value $\sum m_v$ is negligible in relation to the mass of a hydrogen atom (0,00004%), formula (1-16) can be written as:
Thus, the calculated mass of the hydrogen atom almost completely coincided with the experimental mass of the hydrogen atom. This result directly confirms the correctness of formulas (1-11), (1-12), as well as the value obtained using the formula for the Schwarzschild radius $m_0 = \frac{\sqrt{8} q}{c} = 1,511593 \cdot 10^{-27}$ kg. The main result of the above proof is that the coincidence of the calculated by the formula and the experimental mass of the hydrogen atom confirms the existence of gravitational cells and strings.

Let's give one more proof of the existence of gravitational cells and strings and at the same time get a practical scientific result. To do this, consider the gravitational interaction of two ordinary masses, from where we select the formula for the interaction of two gravitational cells:

$$E = \frac{e_1}{d^2} \frac{m}{m} \quad \text{or} \quad E = \frac{e_1}{d^2} \quad (1-19)$$

where $E$ is the strength of the gravitational string between the cells (gravitational field), m/s$^2$

$e_1$ – energy of the gravitational string, $1,108293 \cdot 10^{-37}$ J.

$d$ is the distance between two gravitational cells, m.

$m$ is the mass of the gravitational cell, $1,660539 \cdot 10^{-27}$ kg.

The gravitational string between the cells is not in a static state: it constantly vibrates. Moreover, its vibrational velocity $v$ directly depends on the magnitude of
the strength of the gravitational string (gravitational field) $E$ between the cells and Planck's constant and obeys the following formula:

$$v = \frac{E}{h} \quad (1-20)$$

where $v$ is the vibrational velocity of the gravitational string, m/s. $h$ is Planck's constant.

Hence, based on the formulas $E = \frac{e_1}{d^2}$ and $E = h \cdot v$, we obtain the following formula:

$$v = k_{\text{conv.}} \frac{e_1}{h \cdot d^2} \quad \text{or} \quad v = \frac{e_1}{h \cdot d^2} \quad (1-21)$$

$k_{\text{conv.}}$ – coefficient for converting units of measurement, where $k_{\text{conv.}} = 1 \text{ m}^3$.

The vibrational speed of the string $v$ must have an upper limit, which is equal to the speed of propagation of light in vacuum: $v_{\text{max}} = c$. Hence it follows that there must be a minimum distance $d_{\text{min}}$ at which the formula stops acting:

$$d_{\text{min}} = \sqrt{\frac{e_1}{h \cdot c}} = \sqrt{\frac{1.108293 \cdot 10^{-37}}{6.62607 \cdot 10^{-34} \cdot c}} = 0.747 \mu m \quad (1-22)$$

Calculated by the formula distance $d_{\text{min}} = 0.747 \mu m$ almost completely coincides with the beginning of the Casimir force. (The experiments carried out to study the Casimir effect confirm this). It is precisely starting from a distance of 1 micron between two parallel plates that the Casimir force begins to manifest itself significantly, which replaces the gravitational interaction. Taking into account the large orders of the physical quantities used in the formula ($10^{-37}$, $10^{-34}$, $10^8$), a random coincidence of the experimental and calculated by the formula (1-22) result is completely excluded. Thus, the distance $d_{\text{min}} = 0.747 \mu m$ should be
considered as the boundary of the transformation of the gravitational interaction into another, much stronger interaction. Hence it follows that the formula (1-22) on the basis of which the result $d_{\text{min}} = 0.747 \, \mu\text{m}$ was obtained, is correct. Therefore, the correct are the formulas (1-19), (1-20), (1-21) from which this formula was derived. In turn, the correctness of the basic formulas confirms the existence of gravitational cells and strings.

(For a better perception of information, some formulas do not specifically set conversion factors for units of measurement, which are equal to 1).

**Results.**

The main results of this study should include the introduction of such important components as gravitational cells and gravitational strings into the concept of the gravitational field. This circumstance made it possible to obtain new physical formulas and new physical indicators. This should include the formula for the gravitational constant, the formula for the gravitational quantum, the formula for the electron mass, the formula for the mass of the hydrogen atom, the mass of the gravitational cell, the value of the gravitational quantum, etc. All the results obtained using the new formulas are fully correlated with the experimental data. The indicators obtained by the new formulas coincide with the experimental indicators with an accuracy of $10^{-7}$ (the mass of a hydrogen atom, etc.). In this case, it is especially important that the new formulas are based on fundamental physical constants without introducing additional indicators and correction factors.
**Conclusion.**

In this work, for the first time, it was possible to include in the gravitational field such concepts as gravitational cells and gravitational strings. Planck's formula has also been successfully embedded in the gravitational field. All of the above made it possible to obtain such scientific results as the formula for the gravitational constant, the formula for the mass of an electron, the formula for the hydrogen atom, the formula for the minimum distance of the gravitational field, etc. All new formulas were fully confirmed by experimental data. In this work, the concept of a gravitational quantum is introduced and its value is determined. Also, a new physical constant was obtained - the mass of the gravitational cell of a black hole.

Further research in this direction will be continued.
Declarations

1. **Availability of data and materials.**
   All data obtained and analyzed in the course of this study is included in this article.

2. **Competing interests.** Not applicable (there are no competing interests).

3. **Funding.** Not applicable.

4. **Authors' contributions.** Not applicable.

5. **Acknowledgements.** Not applicable.
