Abstract

Dynamical mass estimates down to the planet-mass regime can help to understand planet formation. We present Atacama Large Millimeter/submillimeter Array (ALMA) 1.3 mm observations of FW Tau C, a proposed ~10 $M_{\oplus}$ planet-mass companion at ~330 au from the host binary FW Tau AB. We spatially and spectrally resolve the accretion disk of FW Tau C in $^{12}$CO (2–1). By modeling the Keplerian rotation of the gas, we derive a dynamical mass of ~0.1 $M_{\odot}$. Therefore, FW Tau C is unlikely a planet, but rather a low-mass star with a highly inclined disk. This also suggests that FW Tau is a triple system consisting of three ~$0.1 M_{\odot}$ stars.

Key words: accretion, accretion disks – planets and satellites: individual (FW Tau C) – stars: individual (FW Tau) – techniques: interferometric

1. Introduction

In the past ~10 years, many planet-mass companions at wide separations (few to tens of $M_{\text{Jup}}$: tens to hundreds of astronomical units from host stars) have been discovered in direct imaging surveys. Their masses are usually determined by comparing observables like luminosity and effective temperature to predictions from evolutionary and atmospheric models (e.g., Chabrier et al. 2000; Marley et al. 2007; Spiegel & Burrows 2012; Baraffe et al. 2015), which vary widely depending on the formation pathway (e.g., core accretion versus gravitational instability). As a result, it would be valuable if masses could be dynamically measured. As some of these substellar companions are young ($\lesssim$10 Myr) and have features associated with active accretion (e.g., Zhou et al. 2014), their dynamical masses can be measured if their accretion disks can be spatially and spectrally resolved.

Among all of the known wide-separation companions, the proposed planet-mass object FW Tau C is the prime target to search for a Keplerian-rotating disk. FW Tau C is a tertiary companion located at ~2″/3 projected separation (~330 au) to FW Tau AB, a close binary (~0″08) of nearly equal-mass stars (~0.1 $M_{\odot}$) in the 2 Myr Taurus–Aquira star-forming region. FW Tau C was discovered by White & Ghez (2001) in their survey of binary stars, and its common proper motion was recently confirmed (Kraus et al. 2014). Studies have shown that FW Tau C has a rather flat near-infrared continuum owing to accretion-induced veiling, as well as many emission lines indicative of outflow and accretion activities (White & Ghez 2001; Bowler et al. 2014). The accretion disk was previously detected by the Atacama Large Millimeter/submillimeter Array (ALMA) in 1.3 mm dust continuum (Kraus et al. 2015) and $^{12}$CO (2–1) (Caceres et al. 2015), and a 1–2 $M_{\odot}$ of dust was inferred. Despite these observational efforts, FW Tau C’s nature remains enigmatic because strong veiling inhibits accurate mass estimates. Kraus et al. (2014) derived a planetary mass of $10 \pm 4 M_{\text{Jup}}$ from its dereddened $K'$ flux, while Bowler et al. (2014) suggested that FW Tau C could be a 0.03–0.15 $M_{\odot}$ brown dwarf or low-mass star embedded in an edge-on disk in order to explain its flat $K$-band spectrum and faint optical and near-infrared brightness.

Accurate mass measurement is therefore key to distinguishing the planet-mass scenario from the stellar-mass scenario. Here, we present the new ALMA 1.3 mm data from Cycle 3. With a ~0″2 beam and ~0.3 km s$^{-1}$ velocity resolution, we spatially and spectrally resolve the gas disk and derive a dynamical mass of FW Tau C by modeling the Keplerian rotation. Parameters of the FW Tau system are summarized in Table 1.

2. Methodology

2.1. Observations and Data Reduction

FW Tau was observed with ALMA Band 6 during Cycle 3, on 2016 September 14. During the observations thirty-six 12 m antennas were available, with baselines ranging from 15 to 3247 m. The Band 6 receiver was configured to have three basebands set up for dust continuum observations, centered at 233.0, 246.0, and 248.0 GHz and each with 2 GHz of bandwidth. The last baseband was configured with 3840 0.122 MHz channels centered at 230.538 GHz (0.32 km s$^{-1}$ velocity resolution; Hanning smoothed) in order to spatially and spectrally resolve $^{12}$CO (2–1) emission from the disk. J0510+1800 was used as the bandpass and flux calibrator, and J0433+2905 was used as the the gain calibrator. The on-source time was ~13 minutes.

The data were reduced using the ALMA pipeline in the CASA package. We employed one iteration of phase-only self-calibration to the 2 GHz continuum basebands. The baseband containing CO emission was much narrower, so it had much lower signal-to-noise ratio in continuum emission and we were unable to obtain good self-calibration solutions. We then CLEANed the calibrated data using the multi-frequency synthesis mode and natural weighting to enhance sensitivity in the images. The continuum map (left panel of Figure 1) has a beam size of $0″29 \times 0″15$ with a position angle (PA) of 160°8, and an rms of 35 $\mu$Jy beam$^{-1}$. The CO channel maps (top panel of Figure 3) have a beam size of $0″30 \times 0″16$ with a PA of 160°3, and a mean rms of 4.5 mJy beam$^{-1}$ in signal-free channels. The integrated moment-zero and moment-one maps of the CO emission are shown in Figure 1.
Table 1
Properties of FW Tau

| Parameter      | FW Tau AB | FW Tau C | References |
|----------------|-----------|----------|------------|
| Distance (pc)  | ~140      |          | 1          |
| Age (Myr)      | ~2        |          | 2          |
| Separation (°) | ~2.3      |          | 3, 4       |
| PA (°)         | ~296      |          | 3, 4       |
| SpT            | M6 ± 1    |          | 3          |
| Av (mag)       | ~0.4      |          | 3          |
| log(L/L⊙)      | ~−1.1²    |          | 5          |
| Mass (M⊙)      | ~0.1²     | ~0.1     | 5, 6       |

Note: ² For each component.

2.2. Disk Modeling: Continuum

The continuum emission from FW Tau C is, at best, only marginally resolved by our observations, so we use a simple geometrical model to fit the data. We assume that the continuum emission traces a uniform brightness disk, with a 1.3 mm brightness $F_n$, a radius $R_{disk}$, and some inclination $i$ and position angle PA. We also allow the centroid of the emission to vary in our fit. We fit the model directly to the continuum visibilities using the Markov Chain Monte Carlo (MCMC) package emcee (Foreman-Mackey et al. 2013).

In order to measure the dust mass of the system, we assume that the continuum emission traces optically thin dust so that we can estimate the disk mass from

$$M_{disk} = \frac{F_n D^2}{\kappa_v B_v(T)}$$

(Beckwith et al. 1990). We use standard assumptions of $T = 20$ K and $\kappa_v = 2.3 \text{ cm}^2 \text{ g}^{-1}$ and a distance to FW Tau C of 140 pc.

2.3. Disk Modeling: Keplerian Rotation

Unlike the 1.3 mm continuum emission, FW Tau C’s gas disk is well resolved by our $^{12}$CO (2–1) observations (see Figure 1), including a clear detection of spatially resolved Keplerian rotation. To model the data and determine disk and stellar parameters, we follow the modeling procedure described in Czekala et al. (2015) to fit our channel maps with synthetic channel maps produced from radiative transfer models. Such models can be used to measure disk parameters such as radius and inclination, as well as the stellar (or planetary) mass (Czekala et al. 2015, 2016). Although we follow the procedure outlined by Czekala et al. (2015), we have developed our own codes to run and fit these models to our data set.

We assume that the $^{12}$CO (2–1) emission comes from a flared accretion disk, with a density profile described by

$$\rho(R, z) = \frac{\Sigma(R)}{\sqrt{2\pi}} \frac{1}{h(R)} \exp\left[-\frac{1}{2}\left(\frac{z}{h(R)}\right)^2\right].$$

where $R$ and $z$ are defined in cylindrical coordinates, and $\Sigma(R)$ and $h(R)$ are the surface density and disk scale height, respectively. We assume that the disk has a power-law surface density profile:

$$\Sigma(R) = \Sigma_0 \left(\frac{R}{R_0}\right)^{-\gamma},$$

and we calculate the CO column density from this surface density profile as

$$N_{CO}(R) = \frac{X_{CO} \Sigma(R)}{\mu \ m_H}.$$
cell and produce synthetic $^{12}$CO (2–1) channel maps for a given set of model parameters. Those synthetic channel maps are Fourier transformed and fit directly to the visibilities using the MCMC fitting package \texttt{emcee} (Foreman-Mackey et al. 2013), with uniform priors for all parameters. Although these models are computationally expensive, they can be run on powerful supercomputers so that the computations are spread out over a large number of central processing units (CPUs). For this particular instance, we run over 128 CPUs on the University of Arizona El Gato supercomputer, and the modeling took a few days to converge. The models were determined to be converged when the \texttt{emcee} walkers had reached a steady state with measured best-fit values changing minimally over a large number of steps.

3. Results

Figure 1 shows the 1.3 mm dust continuum, the $^{12}$CO (2–1) integrated intensity map (moment 0), and the intensity-weighted velocity map (moment 1) of the FW Tau C disk. Similar to Kraus et al. (2015) and Caceres et al. (2015), no signal is found from the close binary FW Tau AB, and the 3σ upper limit for a unresolved source suggests a dust mass $\lesssim 0.07 M_\oplus$. It is known that close binaries can shorten disk lifetimes (e.g., Cieza et al. 2009), so the disk around FW Tau AB may be depleted already. For the companion FW Tau C, its dust disk is compact and likely unresolved; in contrast, the gas disk is more extended and clearly shows a Keplerian rotation.

Figure 2 is the position–velocity diagram constructed along the major axis of the gas disk. On top of the PV diagram we also plot the Keplerian rotation curves for 10 $M_{\text{Jup}}$ and 0.1 $M_\odot$ objects. It is clear that the velocity profile of the FW Tau C disk is incompatible with the 10 $M_{\text{Jup}}$ rotation curve, but more consistent with that of a 0.1 $M_\odot$ star. Our disk modeling (see Figure 3 and Table 2) also indicates that FW Tau C’s mass is $\sim 0.1 M_\odot$, about 10 times higher than the 10 $M_{\text{Jup}}$ suggested by Kraus et al. (2014). Hence, FW Tau C is not a planetary-mass object, but is rather a low-mass star with an inclined disk, as suggested by Bowler et al. (2014). The high mass of FW Tau C is also in agreement with some features in its spectrum that closely resemble T Tauri stars (Bowler et al. 2014). Our

**Figure 1.** Left: ALMA 1.3 mm dust continuum map of the FW Tau system. The primary stars FW Tau AB are not detected (dashed circle). Middle: ALMA $^{12}$CO (2–1) integrated intensity map (moment 0) shows a resolved accretion disk around FW Tau C. Right: the velocity field (moment 1) of FW Tau C’s disk clearly shows a Keplerian rotation. The black cross marks the center of the disk in 1.3 mm continuum. Beam size $\sim 0''29 \times 0''16$ and PA $\sim 160^\circ$. North is up and east is left.

![Figure 2](image2.png)  
**Figure 2.** Position–velocity diagram constructed along the major axis of the FW Tau C disk. Keplerian rotation curves for a 0.01 $M_\odot$ ($\sim 10 M_{\text{Jup}}$) planet and a 0.1 $M_\odot$ star are also plotted. FW Tau C is more consistent with a 0.1 $M_\odot$ star.

| Parameter | Value |
|-----------|-------|
| $M_\star$ ($M_\odot$) | 0.098 ± 0.015 |
| $M_{\text{disk, dust}}$ ($M_\odot$) | 1.15 ± 0.01 |
| $M_{\text{disk, gas}}$ ($M_\odot$) | 0.58 ± 0.13 |
| $R_{\text{disk}}$ (au) | 141.9 ± 6.6 |
| $\gamma$ | 1.63 ± 0.14 |
| $T_\text{eff}$ (K) | 62.1 ± 34.6 |
| $q$ | 0.14 ± 0.10 |
| $\xi$ (km s$^{-1}$) | 0.65 ± 0.08 |
| $v_{\text{sys}}$ (km s$^{-1}$) | 6.10 ± 0.02 |
| $i$ ($^\circ$) | 62.8 ± 2.4 |
| PA ($^\circ$) | 40.6 ± 1.5 |

![Table 2](image3.png)  
**Table 2.** FW Tau C Disk Properties
Figure 3. We show our CO (2–1) channel maps (top) as well as the best-fit Keplerian disk model synthetic channel maps (center) and the residual channel maps (bottom). The model channel maps are made by sampling the model at the same baselines as the data and Fourier transforming to produce images. The residual channel maps are produced by subtracting the model visibilities from the visibility data and Fourier transforming to produce maps. The contours start at $3\sigma = 13.5\, \text{mJy beam}^{-1}$ and are at intervals of $3\sigma$. 

The Astrophysical Journal Letters, 846:L26 (5pp), 2017 September 10 Wu & Sheehan
observations therefore suggest that FW Tau is a young triple system in which each of the stars has a mass of \( \sim 0.1 M_\odot \).

Searches for accretion disks in millimeter around directly imaged planet-mass companions have not yielded positive results (e.g., Isella et al. 2014; Bowler et al. 2015; MacGregor et al. 2017; Ricci et al. 2017; Wolff et al. 2017; Wu et al. 2017), although the disk around the free-floating planet OTS 44 has recently been imaged (Bayo et al. 2017). Current flux upper limits imply that these wide companion disks might have \(< 0.1 M_\odot\) of dust, which in turn could imply a very short disk lifetime. Future deep imaging down to a sublunar mass regime is perhaps needed to detect these disks, or place stringent constraints on their masses, and further elucidate the mass growth history of the planetary-mass companions at wide orbits.

Finally, we summarize our disk modeling results as below and also in Table 2. Modeling the FW Tau C’s dust disk as a circular Gaussian, we find that it has a 1.3 mm flux of \( \sim 2.06 \text{ mJy} \), which equates to a dust mass of \( \sim 1.15 M_\oplus \), and is consistent with previous measurements in Kraus et al. (2015) and Caceres et al. (2015). For the gas disk, our radiative transfer modeling, as demonstrated in Figure 3, finds that the gas disk has a radius of \( \sim 140 \text{ au} \), inclination of \( \sim 63^\circ \), PA of \( \sim 41^\circ \), systemic velocity of \( \sim 6.1 \text{ km s}^{-1} \), and gas mass of \( \sim 0.58 M_\odot \). Although recent studies have shown a low gas-to-dust ratio in protoplanetary disks (e.g., Williams & Best 2014; Ansdel et al. 2016), we caution that with a single optically thick CO line, we are very likely to underestimate the true gas mass by a factor of few or even orders of magnitude (e.g., Yu et al. 2017). As Yu et al. (2017) pointed out, to accurately derive the gas mass, one should observe low-transition lines to ameliorate the optical-depth effects and should also use multiple CO isotopologues to characterize the chemical depletion and abundance variation across the disk.

4. Summary

FW Tau C is a wide-orbit companion at \( \sim 330 \text{ au} \) from the close binary FW Tau AB that has been suggested to have a planet-like mass of \( 10 M_{\text{Jup}} \). Here, we have used ALMA to detect FW Tau C’s accretion disk in a 1.3 mm dust continuum and \(^{12}\text{CO} (2–1)\) emission. We find that the gas motion is both spatially and spectrally resolved and clearly follows Keplerian rotation, enabling a dynamical mass estimate of the central object. We show that FW Tau C’s mass is in fact \( \sim 0.1 M_\odot \), so it is more likely a low-mass star embedded in an inclined accretion disk.
