(Dated: May 27, 2014)

We apply the many-particle quantum hydrodynamics including the Coulomb exchange interaction to magnetized quantum plasmas. We consider a number of wave phenomenon under influence of the Coulomb exchange interaction. Since the Coulomb exchange interaction affects longitudinal and transverse-longitudinal waves we focus our attention to the Langmuir waves, Trivelpiece-Gould waves, ion-acoustic waves in non-isothermal magnetized plasmas, the dispersion of the longitudinal low-frequency ion-acoustic waves and low-frequencies electromagnetic waves at $T_e \gg T_i$. We obtained the numerical simulation of the dispersion properties of different types of waves.

Keywords: quantum plasmas, exchange interaction, ion-acoustic waves, quantum hydrodynamics

I. INTRODUCTION

The many-particle quantum hydrodynamics (MPQHD) method had been developed for the systems of charged or neutral particles in [1]. General form of the quantum exchange correlations was derived there. The MPQHD for three dimensional spin 1/2 quantum plasmas with the Coulomb exchange and the spin-spin exchange interactions was obtained in 2001 in Ref. [2]. Theory of ultracold quantum gases of neutral atoms, including derivation and generalization of the Gross-Pitaevskii equation, was constructed in terms of the MPQHD in 2008 [3]. Further development of the MPQHD with exchange interaction for low dimensional and three dimensional Coulomb quantum plasmas has been recently performed in Ref. [4].

A quantum mechanics description for systems of N interacting particles is based upon the many-particle Schrodinger equation (MPSE) that specifies a wave function in a 3N-dimensional configuration space. As wave processes, processes of information transfer, and other spin transport processes occur in 3D physical space, it becomes necessary to turn to a mathematical method of physically observable values that are determined in a 3D physical space. The fundamental equations of the microscopic quantum hydrodynamics of fermions in an external electromagnetic field had been derived using the many-particle Schrodinger equation [2], [3], [6]. Recently there has been an increased interest in the properties of quantum plasmas [7] - [12]. Dispersion relations for linear waves in amedum formed by electrons and ions and traversed by a beam of neutrons whose velocity has a nonzero constant component had been derived by methods of quantum hydrodynamics in [13]. The dispersion of waves, existed in the plasma in consequence of dynamic of the magnetic moments had been investigated in [14]. [15]. The instabilities at propagation of the neutron beam through the plasma had been showed.

The extended vorticity evolution equation for the quantum spinning plasma had been derived and the effects of new spin forces and spin-spin interaction contributions on the motion of fermions, evolution of the magnetic moment density and vorticity generation had been predicted [14]. The spin-orbital corrections to the propagation of the whistler waves in a astrophysical quantum magnetoplasma composed by mobile ions and electrons had been predicted in [17]. The hydrodynamic model including the spin degree of freedom and the electromagnetic field had been discussed in [15]. The quantum hydrodynamics for the research of many-particles systems had been developed in [3], [19], [20].

The Coulomb exchange interactions are of great importance in many systems as well as for magnetic phenomena, and have no classical analogy. The Coulomb exchange effects had been included in a QHD picture [4] for the Coulomb quantum plasmas. To do this, the fundamental equations that determine the dynamics of functions of three variables, starting from MPSE had been derived. This problem has been solved with the creation of a many-particle quantum hydrodynamics method. The contribution of the exchange interaction in the dispersion of the Langmuir [4] and ion-acoustic waves for three and two dimensional quantum plasmas had been shown. It had been derived that the exchange interaction between particles with same spin direction and particles with opposite spin directions are different. Recently, the kinetic plasma model containing fermion exchange effects were investigated in [21] and the influence of exchange effect on low frequency dynamics, in particular ion acoustic waves was predicted. The generalization of the Vlasov equation to include exchange effects was presented allowing for electromagnetic mean fields and the correction to classical Langmuir waves in plasmas was found in [22].

The influence of electron-exchange and quantum screening on the collisional entanglement fidelity for the elastic electronion collision was investigated [23]. The effective Shukla– Eliasson potential and the partial wave method had been used to obtain the collisional entanglement fidelity in quantum plasmas as a function of the

II. MODEL

We apply the equations for the system of charged particles in the external magnetic field \( \mathbf{B} \). For a 3D system of particles the continuity equations and the momentum balance equations for electrons and ions may be written down in terms of electrical intensity of the field that is created by charges of the particle system. Thus the continuity equations for ions and electrons are

\[ \partial_t n_e + \nabla (n_e \mathbf{v}_e) = 0, \quad (1) \]

and

\[ \partial_t n_i + \nabla (n_i \mathbf{v}_i) = 0. \quad (2) \]

The equation of motion for electrons is

\[
\begin{align*}
\frac{m_e n_e}{e_p} (\partial_t + \mathbf{v}_e \nabla) \mathbf{v}_e + \nabla p_e - \frac{\hbar^2}{4m_e n_e} \nabla \left( \frac{\triangle n_e}{n_e} - \frac{(\nabla n_e)^2}{2n_e^2} \right) &= q_e n_e \left( \mathbf{E}_{\text{ext}} + \mathbf{E}_{\text{int}} + \frac{1}{c} \mathbf{v}_e [\mathbf{B}, \mathbf{B}_{\text{ext}}] \right) + 2^{4/3} q_e^2 \frac{3}{\pi} \frac{1}{\sqrt{n_e \nabla n_e}}, \quad (3)
\end{align*}
\]

and the Euler equation for ions

\[
\begin{align*}
\frac{m_i n_i}{e_i} (\partial_t + \mathbf{v}_i \nabla) \mathbf{v}_i + \nabla p_i - \frac{\hbar^2}{4m_i n_i} \nabla \left( \frac{\triangle n_i}{n_i} - \frac{(\nabla n_i)^2}{2n_i^2} \right) &= q_i n_i \left( \mathbf{E}_{\text{ext}} + \mathbf{E}_{\text{int}} + \frac{1}{c} [\mathbf{v}_i, \mathbf{B}_{\text{ext}}] \right) + 2^{4/3} q_i^2 \frac{3}{\pi} \frac{1}{\sqrt{n_i \nabla n_i}}.
\end{align*}
\]

The second terms on the left sides of Eq. (3) and (4) are the gradient of the thermal pressure or the Fermi pressure for degenerate electrons and ions. It appears as the thermal part of the momentum flux related to distribution of particles on states with different momentum. The third terms are the quantum Bohm potential appearing as the quantum part of the momentum flux. In the right-hand sides of the Euler equations we present interparticle interaction and interaction of particles with external electromagnetic fields. The first group of terms in the right-hand side of the Euler equations describe interaction with the external electromagnetic fields. The force fields of Coulomb exchange interaction of electrons and positrons (the second terms on the right side of (3) and (4)) are obtained for fully polarized systems of identical particles. For polarized systems of electrons or ions equations of state appears \( p_{\text{a,3D} \uparrow \uparrow} = \frac{2^{2/3}}{9} h^2 T_{\text{a,3D}}^{5/3}/5m_e \) for 3D mediums, where subindex \( \uparrow \uparrow \) means that all particles have same spin direction. The ratio of polarization \( \eta = \frac{n_{\uparrow \uparrow} - n_{\downarrow \downarrow}}{n_{\uparrow \uparrow} + n_{\downarrow \downarrow}} \), with indexes \( \uparrow \) and \( \downarrow \) means particles with spin up and spin down. In general case of partially polarized system of particles we can write \( p_{\text{a,3D} \uparrow \downarrow} = \frac{2^{2/3}}{9} h^2 T_{\text{a,3D}}^{5/3}/5m_e \) for partially polarized systems, that means that part of states contain two particle with opposite spins and other occupied states contain one particle with same spin direction \( \uparrow \uparrow \uparrow \).

\[
\eta = \frac{1}{2} \left( 1 + \eta \right)^{5/3} + \left( 1 - \eta \right)^{5/3}, \quad (5)
\]

For partially polarized particles the force fields reappear as \( \mathbf{F}_{C,a(3D)} = \zeta_{3D} q_a^2 \frac{2}{\pi} \sqrt{\nabla n_a} \nabla n_a \), with

\[
\zeta_{3D} = (1 + \eta)^{4/3} - (1 - \eta)^{4/3} \quad (6)
\]

We should mention that coefficient \( \zeta_{3D} \sim \eta \) is proportional to spin polarization. Limit cases of \( \zeta_{3D} \) are \( \zeta_{3D}(0) = 0, \zeta_{3D}(1) = 2^4/3 \).

Considering two electrons one finds that full wave function is anti-symmetric. If one has two electrons with parallel spins one has that wave function is symmetric on spin variables, so it should be anti-symmetric on space variables. In opposite case of anti-parallel spins one has anti-symmetry of wave function on spin variables and symmetry of wave function on space variables.

Systems of unpolarized electrons then average numbers of electrons with different direction of spins equal to each other, we find that average number of particles for a chosen with parallel and anti-parallel spins is the same. Consequently we have that average exchange interaction equals to zero. In partly polarized systems the numbers of particles with different spin are not the same. In this case a contribution of the average exchange interaction appears. At full measure it reveals in fully polarized system then all electrons have same direction of spins. In
accordance with the previous discussion we find that exchange interaction, for this configuration, gives attractive contribution in the force field.

III. APPLICATIONS

In this section we consider small perturbations of equilibrium state describing by nonzero particle concentration $n_0$, and zero velocity field $v_0 = 0$ and electric field $E_0 = 0$.

Assuming that perturbations are monochromatic

$$
\begin{pmatrix}
\delta n_c \\
\delta n_i \\
\delta v_c \\
\delta v_i \\
\delta E \\
\delta B
\end{pmatrix} =
\begin{pmatrix}
N_A c \\
N_A i \\
V_A c \\
V_A i \\
E_A \\
B_A
\end{pmatrix}
e^{-i\omega t+i\mathbf{k}\cdot\mathbf{r}},
$$

(7)

we get a set of linear algebraic equations relatively to $N_A$ and $V_A$. Condition of existence of nonzero solutions for amplitudes of perturbations gives us a dispersion equation in the form of

$$
\omega_{3D}(k) = kv_{s,3D}\sqrt{1 - \frac{\zeta_{3D}}{3\pi \frac{\epsilon_0}{m_e}} \frac{\omega_{F,3D}^2}{\omega_{F,e,3D}^2}}
$$

$$\times \frac{1}{\sqrt{1 + (kr_{D,3D})^2}} \left(1 - \frac{\zeta_{3D}}{3\pi \frac{\epsilon_0}{m_e}} \frac{\omega_{F,3D}^2}{\omega_{F,e,3D}^2}\right),
$$

(10)

where the dispersion of quantum Langmuir waves with the account of Coulomb exchange interactions (9) is presented at Fig. (1). In general case of partially polarized system of particles with spin up and spin down, the dispersion of quantum Langmuir waves as a function of ratio of polarizability with account of Coulomb exchange interactions (9) is presented at Fig. (2).

We see that the first term in Eq. (9) is proportional to the electron equilibrium concentration $n_{0e}$ and grows faster then the second term $\sim n_{0e}^{1/3}$. The third term has an intermediate rate of grow being proportional to $\sim n_{0e}^{2/3}$. The Coulomb exchange interaction is larger than the Fermi pressure when $n_{0e} \lesssim 10^{22} \text{cm}^{-3}$, this situation is realized in metals and semiconductors, but in the astrophysical objects like white drafts $n_{0e} \lesssim 10^{28} \text{cm}^{-3}$, the Fermi pressure is larger than the Coulomb exchange interaction.

We have considered high frequency waves. Next step is consideration of the low frequency excitations

$$
\omega_{3D}(k) = kv_{s,3D}\sqrt{1 - \frac{\zeta_{3D}}{3\pi \frac{\epsilon_0}{m_e}} \frac{\omega_{F,3D}^2}{\omega_{F,e,3D}^2}}
$$

$$\times \frac{1}{\sqrt{1 + (kr_{D,3D})^2}} \left(1 - \frac{\zeta_{3D}}{3\pi \frac{\epsilon_0}{m_e}} \frac{\omega_{F,3D}^2}{\omega_{F,e,3D}^2}\right),
$$

(10)

where $v_{s,3D} = \sqrt{m_e/m_i\sqrt{3\pi}} \cdot v_{F,e,3D}/3$ is the three dimensional velocity of sound, $r_{D,3D} = \sqrt{3\pi v_{F,e,3D}/(\omega_{F,e,3D})}$ is the Debye radius. In formula (9) and similar formulas below we extract contribution of the Fermi pressure. Hence formulas for ion-acoustic waves contains well-known contribution of the pressure multiplied by factor showing contribution of exchange interaction.

FIG. 1: The figure shows the dispersion characteristic of the quantum Langmuir wave frequency $\omega$ versus the wave vector $k$, which is described by the equation (9). The green branch of dispersion is presented the classical high frequency Langmuir wave, the red and blue branches characterize the Coulomb exchange interactions and quantum Bohm potential influence, where $n_{0e} \simeq 10^{22} \text{cm}^{-3}$, $\eta = 1$.

$$
\omega_{F,e,3D}^2 = \frac{4\pi e^2 n_{0,3D}}{m_e}.
$$

(8)

$$
\omega^2 = \omega^2_{F,e,3D} - \xi_{3D} \sqrt{\frac{3}{\pi} \frac{e^2}{m_e}} \sqrt{n_{0e}} k^2 
$$

$$+ \delta_{3D} \left(\frac{3\pi^2}{2\sqrt{3}m_e^2} k^2 n_{0e}^2 \frac{1}{2} + \frac{h^2 k^4}{4m_e^2}\right).
$$

(9)

FIG. 2: The figure shows the dispersion characteristic of the quantum Langmuir wave frequency $\omega$ as a function of the wave vector $k$ and the ratio of polarizability $\eta$, which is described by the equation (9). The Coulomb exchange interactions and quantum Bohm potential are taken into account and $n_{0e} \simeq 10^{22} \text{cm}^{-3}$. 

FIG. 1: The figure shows the dispersion characteristic of the quantum Langmuir wave frequency $\omega$ versus the wave vector $k$, which is described by the equation (9). The green branch of dispersion is presented the classical high frequency Langmuir wave, the red and blue branches characterize the Coulomb exchange interactions and quantum Bohm potential influence, where $n_{0e} \simeq 10^{22} \text{cm}^{-3}$, $\eta = 1$. 

$$
\omega_{F,e,3D}^2 = \frac{4\pi e^2 n_{0,3D}}{m_e}.
$$

(8)

$$
\omega^2 = \omega^2_{F,e,3D} - \xi_{3D} \sqrt{\frac{3}{\pi} \frac{e^2}{m_e}} \sqrt{n_{0e}} k^2 
$$

$$+ \delta_{3D} \left(\frac{3\pi^2}{2\sqrt{3}m_e^2} k^2 n_{0e}^2 \frac{1}{2} + \frac{h^2 k^4}{4m_e^2}\right).
$$

(9)
In the long wavelength limit we have
\[ \omega(k) = k v_{s,3D} \sqrt{1 - \frac{\zeta_{3D}}{\nu_{3D}} \frac{3}{4\pi} \sqrt{\frac{3}{\pi}} \frac{\omega_{Li,3D}^2}{\eta_{0e,3D}^2 v_{Fe,3D}}}. \]  
(11)

In the short wavelength limit we find
\[ \omega^2(k) = \omega_{Li,3D}^2. \]
(12)

IV. ION-ACOUSTIC WAVES IN NON-ISOTHERMAL MAGNETIZED PLASMAS

Let’s discuss the ion-acoustic waves in non-isothermal magnetized plasmas with \( T_e \gg T_i \approx 0 \) at \( \Omega_i^2 \gg \omega_{Li}^2 \gg \Omega_i^2 \). In these conditions the ion-acoustic waves exhibit two branches of wave dispersion. One branch is at \( \omega < \Omega_i \) and another one at \( \omega > \Omega_i \).

Corresponding dispersion equation appears as
\[ 1 - \frac{k^2 \omega_{Li}^2}{k^2(\omega^2 - \Omega_i^2)} - \frac{k^2 \omega_{Li}^2}{k^2 \omega^2} + \frac{\omega_{Te}^2}{k^2 v_{Te}^2} = 0, \]
(13)

where \( v_{Te}^2 \) - is the thermal electron velocity. Using the approximation \( \omega_{Li}^2 \gg \Omega_i^2 \) and \( \theta \neq 0 \) we find
\[ \omega^2 = \frac{\omega_{Li}^2 + \Omega_i^2 (1 + \omega_{Li}^2/k^2 v_s^2)}{1 + \omega_{Li}^2/k^2 v_s^2}, \]  
(14)

and
\[ \omega^2 = \frac{\omega_{Li}^2 \Omega_i^2 \cos^2 \theta}{\omega_{Li}^2 + \Omega_i^2 (1 + \omega_{Li}^2/k^2 v_s^2)}, \] 
(15)

where
\[ v_s^2 = -\xi_{3D} \frac{e^2}{m_i} \sqrt{\frac{3}{\pi}} \sqrt{\eta_{0e}}. \]
contains the Coulomb exchange interaction between electrons (the first term). The second term appears from the Fermi pressure. and the third term describes contribution of the quantum Bohm potential.

Solutions of the equation (13) for the different ratio of polarizability are presented by two branches of the dispersion at Fig. [3], [4] and [5].

When the distribution of the wave is parallel to the background magnetic field θ = 0 the ion-acoustic modes have the form of

\[ \omega^2 = \Omega_i^2 - k^2 \frac{\xi_{3D} e^2}{m_i} \sqrt{\frac{3}{\pi}} \sqrt{n_e} + \vartheta_{3D} \left( \frac{3 \pi^2 h^2 n_{o e}}{3 m_e m_i} + \frac{h^2 k^2}{4 m_e m_i} \right). \]  

(16)

VI. THE TRIVELPIECE-GOULD WAVES

Trivelpiece-Gould wave \cite{25, 26} is a longitudinal wave appearing along with the Langmuir wave at propagation of waves at an angle to external magnetic field \( k_x \neq 0 \) and \( k_z \neq 0 \). It is a low-frequency wave with \( \omega \ll \Omega_i \).

It exists at long wavelengths limit \( \ll 1 \), \( k^2 v_T e \ll \omega^2 \). All of these conditions give the following dispersion equation

\[ 1 - \frac{\omega_i^2}{\omega^2} \frac{k_x^2}{k^2} + \frac{\omega_i^2}{k^2} \frac{k_z^2}{v_T^2} = 0 \]  

(19)

Dispersion dependence of the Trivelpiece-Gould wave in the classical magnetic field appears as \cite{26}

\[ \omega^2 = \frac{\omega_i^2 \cos^2 \theta}{1 + \frac{\omega_i^2 \sin^2 \theta}{\Omega_i^2}}. \]  

(20)

It looks like thermal velocity does not affect this spectrum. If it is correct we can mention that the exchange interaction does not influence it either. In the quantum external magnetic field the thermal velocity effect might be important. This corresponds to a regime of very strong magnetic field in which the external field strength approaches or exceeds the quantum critical magnetic field, \( B_0 \geq 4.4 \times 10^{13} \text{ G} \). Evidently, when \( h \Omega_i >> T_e \) there must exist the frequency

\[ \omega^2 = \frac{m_i \Omega_i \tan^2 \theta}{\hbar}\times \]  

\[ \left( -\xi_{3D} e^2 \sqrt{3} \sqrt{n_e} + \vartheta_{3D} \left( \frac{3 \pi^2 h^2 n_{o e}}{3 m_e m_i} + \frac{h^2 k^2}{4 m_e m_i} \right) \right). \]  

(21)

VI. THE LONGITUDINAL LOW-FREQUENCY ION-ACOUSTIC WAVES IN MAGNETIZED PLASMAS

In absence of external magnetic field longitudinal oscillations exists in electron-ion plasmas with hot electrons and cold ions \cite{25}. They are weakly damping ion-acoustic oscillations \cite{27}. Dispersion of these waves is

\[ \omega_s(k) = \frac{k v_s}{\sqrt{1 + k^2 r_D^2}}, \]  

(22)

where \( r_D = \sqrt{T_e/4 \pi e^2 n_0} \) is the Debye radius, \( v_s = \sqrt{T_e/m_i} \). This solution corresponds to phase velocities of waves, which are intermediate in compare with other parameters of plasmas \( v_i \ll \omega/k \ll v_e \). Therefore thermal velocities of electrons \( v_e = \sqrt{T_e/m_e} \) and ions \( v_i = \sqrt{T_i/m_i} \).

If equilibrium state of a medium reveals distribution function in ferromagnetic domains, the Coulomb exchange interaction gives considerable contribution in spectrum of the longitudinal waves \cite{14}.

It is well-known that an external magnetic field affects the ion-acoustic waves at \( \omega_s(k) \leq \Omega_i \) and \( k_p \leq 1 \). Presence of external magnetic field creates or increases difference in occupation of spin-up and spin-down states. Consequently, account of the Coulomb exchange interaction in magnetized plasmas is even more important than in plasmas with no external magnetic field.

Under conditions \( v_i \ll \omega/k \ll v_e \) we find the following dispersion equation for the longitudinal low-frequency ion-acoustic waves

\[ 1 + \frac{\omega_i^2}{\Omega_i^2} + \left( \frac{\omega_i^2}{k^2 v_T^2} - \frac{\omega_i^2}{\omega^2} - \sin^2 \theta \right) = 0, \]  

(23)

where \( \Omega_{ia} = \frac{q_0 B_0}{m_i e} \) are the electron or ion cyclotron frequency.

Increasing of the Coulomb exchange interaction in compare with the Fermi pressure can break condition of the ion-acoustic wave existence \( v_i \ll |\omega/k| \ll v_e \).

Getting into account the fact that in the problem under consideration the second term in equation (23) much smaller than the third term we find next solution

\[ \omega^2(k, \theta) = \frac{1}{2} \left( \omega_i^2 + \Omega_i^2 \right) \pm \frac{1}{2} \sqrt{(\omega_i^2 + \Omega_i^2)^2 - 4 \omega_i^2 \Omega_i^2 \cos^2 \theta}. \]  

(24)

We have also neglected small anisotropic terms.

In presence of an external magnetic field, there are two longitudinal low-frequency oscillations instead of the ion-acoustic wave.

At \( k \to 0 \) we find from formula (24)

\[ \omega(k, \theta) = k v_s \cos \theta, \]  

and

\[ \omega(k, \theta) = \Omega_i \left( 1 + \frac{k^2 v_i^2 \sin^2 \theta}{2 \Omega_i^2} \right). \]  

(26)
The condition for instability is thus that the negative term of \( v_s^2 \) dominates over all the others. When the Coulomb exchange interactions is larger than Fermi pressure \( n_0 \approx 10^{23}\text{sm}^{-3} \), the solution (25) is instability. The solution (26) is presented at Fig. (6) as a function of \( \eta \).

In opposite limit of small wavelengths \( k \to \infty \), or in other terms \( k r_D \gg 1 \), from formula (24) we obtain
\[
\omega^2_L(\theta) = \frac{1}{2}(\omega^2_L + \Omega_i^2) \pm \frac{1}{2} \sqrt{(\omega^2_L + \Omega_i^2)^2 - 4\omega^2_L\Omega_i^2\cos^2\theta}.
\] (27)

Formula (27) is obtained at \( k^2 \rho_i^2 \ll 1 \). It can be applied at \( \frac{T_e}{\Omega_i} \ll 1 \). Under condition \( \omega_L \ll \Omega_i \) formula (27) does not work. Formula (24) can be applied in the long wavelength limit \( k r_D \ll 1 \) if condition \( \omega_L \gg \Omega_i \) is satisfied.

Under conditions \( k v_s \gg \Omega_i \) and \( k r_D \ll 1 \), we obtain the following solutions from formula (24)
\[
\omega(k) = kv_s,
\] (28)
and
\[
\omega(k, \theta) = \Omega_i \cos \theta.
\] (29)

The Coulomb exchange interaction in (28) is larger than the Fermi pressure when \( n_0 \approx 10^{23}\text{sm}^{-3} \), this situation is realized in metals and semiconductors, but in the astrophysical objects like white drafts the Fermi pressure is larger than the Coulomb exchange interaction.

At \( k \to 0 \) (\( kv_s \ll \Omega_i \)) larger of solutions (24) presented by formula (28) getting to \( \Omega_i \).

We can also present corresponding refractive index
\[
N^2 = \frac{c^2}{v_s^2} \frac{\omega^2 - \Omega_i^2}{\omega^2 - \Omega_i^2 \cos^2 \theta}.
\] (30)

![Figure 6](image1)

**FIG. 6:** The figure shows the dispersion characteristic of the low-frequency oscillations in the long wavelengths \( k \to \infty \) limit, which is described by the equation (26), \( n_0 \approx 10^{18}\text{sm}^{-3} \), \( B_0 = 5 \cdot 10^4 \text{G} \). The red branch characterizes the total polarized system \( \eta = 1 \), the blue mode \( \eta = 0.5 \) and green mode \( \eta = 0.2 \) present the dispersion properties of partially polarized systems.

![Figure 7](image2)

**FIG. 7:** The figure shows the corresponding classical refractive index (26) in the limit of the long wavelength limit \( k r_D \ll 1 \), where the Coulomb exchange interactions are dominate \( \gamma_{\text{ex}}^2 > v^2_s \). System parameters are assumed to be as follows: \( n_0 \approx 10^{15}\text{sm}^{-3} \), \( B_0 = 5 \cdot 10^4 \text{G} \). The blue branch is the index \( c^2/\gamma_{\text{ex}}^2 \).

![Figure 8](image3)

**FIG. 8:** The figure shows the dispersion characteristic of the slow and fast magneto-sonic waves, which is described by the equation (24) in the long wavelength limit \( k r_D \ll 1 \), \( n_0 \approx 10^{23}\text{sm}^{-3} \), \( B_0 = 5 \cdot 10^4 \text{G} \). The red branch characterizes the dispersion of total polarized system \( \eta = 1 \), the blue mode \( \eta = 0.3 \) and green mode \( \eta = 0.2 \) present the dispersion properties of partially polarized systems.

Using the definition (16) the Coulomb exchange pressure can be important for the slow and fast magneto-sonic wave, see Fig. (8).

**VII. THE LOW-FREQUENCY ELECTROMAGNETIC OSCILLATIONS IN THE MAGNETIZED PLASMA**

Here we discuss low-frequencies electromagnetic waves at \( T_e \gg T_i \) under influence of the Coulomb exchange interaction.

Dispersion equation existing in the case under consideration is rather huge. Thus we do not present it here. Nevertheless, we present description of limit cases. In low frequency limit, it corresponds to the long wavelength
limit $k \to 0$, we have the dispersion of the slow and fast
magneto-sonic waves

\[ \omega = kv_A \cos \theta \quad (31) \]

and

\[ \omega = kv_{\pm} \quad (32) \]

where the Alfven velocity is

\[ v_A = c \frac{\Omega_i}{\omega_{L,i}} = \frac{B_0}{\sqrt{4\pi n_0 m_i}} \quad (33) \]

and

\[ v_{\pm}^2 = \frac{1}{2} (v_A^2 + v_s^2) \pm \frac{1}{2} \sqrt{(v_A^2 + v_s^2)^2 - 4v_A^2v_s^2 \cos^2 \theta} \quad (34) \]

For the wave propagating parallel to the external magnetic field $\cos \theta \simeq 0$ the dispersion low (32) has the form

\[ \omega_{\pm} = k \begin{cases} v_A, \\ v_s, \end{cases} \quad (35) \]

Lets consider the longitudinal wave propagating perpendicular to the external magnetic field. The dispersion low (32) takes the form

\[ \omega^2 = k^2 \left( v_A^2 + v_t^2 - \xi_3 D \frac{e^2}{m_i} \sqrt{\frac{3}{\pi}} \sqrt{n_0} \right) \quad (36) \]
\[ + \vartheta_{3D} \left( \frac{3\pi^2}{2} \frac{2/3}{2} \frac{2}{3} \frac{2}{3} \frac{m_e m_i}{4m_e m_i} + \frac{\hbar^2 k^2}{4m_e m_i} \right), \]

\[ \vartheta_{3D} = \frac{1}{2} [(1 + \eta)^{5/3} + (1 - \eta)^{5/3}], \]  

(37)

\[ \xi_{3D} = [(1 + \eta)^{4/3} - (1 - \eta)^{4/3}]. \]

The figure (9) shows regions of importance in parameter space for various quantum plasma effects \( \eta = 1 \). The Fermi-pressure \( \sim v_{Fe}^2 \sim n_{oc}^2 \) becomes important when the Fermi temperature approaches the thermodynamic temperature, when the plasma concentration \( n_0 \geq 10^{25} \text{cm}^{-3} \). The Alfvén mode described by the first term \( v_A^2 \) on the right side of (36). The effects due to the magnetic pressure depend on the magnetic field strength \( v_A^2 \sim n_0^{-1} \). The magnetic pressure effects can be important in regimes of \( n_0 \leq 10^{20} \text{cm}^{-3} \) and external magnetic field \( B_0 \approx 5 \times 10^6 \text{G} \). The quantum regime correspond to lower temperatures. The Coulomb exchange interactions proportional to \( \sim \bar{v}_A^2 \sim n_{oc} \) can be important in regimes of \( 10^{20} \leq n_0 \leq 10^{24} \text{cm}^{-3} \). The Coulomb exchange force does not provide a stabilizing mechanism. The exchange pressure \( \sim \bar{v}_A^2 = \xi_{3D} \left( \frac{3}{2} \frac{\sqrt{n_{oc}}}{3} \frac{2}{3} \right) / m_i \) is the negative pressure term and therefore the source of the instability. But for the high magnitude magnetic field \( B_0 \approx 10^7 \text{G} \), the instability is stabilized.

\[
N^2 = (2N_A^2 + N_s^2 \sin^2 \theta) \frac{\Omega_i^2 \cos^2 \theta - \omega^2}{\Omega_i^2 \cos^2 \theta - \omega^2}, \]

(38)

and

\[
\omega(k, \theta) = \Omega_i \cos \theta \times \]

(39)

where \( N_A = c/v_A, N_s = c/v_s \). The dispersion of quantum slow magneto-sonic waves in the small wavelength limit \( k \rightarrow \infty \) is presented at Fig. (11).

![Image](image.png)

**FIG. 11:** The figure shows the dispersion characteristic of the slow magneto-sonic waves, which is described by the equation (39) in the small wavelength limit \( k \rightarrow \infty \), where the exchange effects are taken into account. The red branch of dispersion represents the classical low, the blue branch includes the dispersion characteristic of quantum slow magneto-sonic waves which occurs due to Bohm quantum potential and the green mode takes account of Coulomb exchange interactions.

**VIII. CONCLUSIONS**

We have briefly described quantum hydrodynamic model for the magnetized quantum plasmas. In our work we consider the electron-electron and ion-ion Coulomb exchange interactions. Using QHD equations with Coulomb exchange force field we analyzed elementary excitations in various physical systems in a linear approximation. We investigated the dispersion properties of the ion-acoustic waves in non-isothermal magnetized plasmas, the Trivelpiece-Gould waves, the longitudinal low-frequency ion-acoustic waves, the magneto-sonic waves, high-frequency and low-frequency electron sound tracing contribution of the exchange interaction. We described the different regimes and showed that the exchanges interactions can lead to instability.
