Is motion under the conservative self-force in black hole spacetimes an integrable Hamiltonian system?

Justin Vines and Éanna É. Flanagan
Department of Physics, Cornell University, Ithaca, NY 14853, USA.

A point-like object moving in a background black hole spacetime experiences a gravitational self-force which can be expressed as a local function of the object’s instantaneous position and velocity, to linear order in the mass ratio. We consider the worldline dynamics defined by the conservative part of the local self-force, turning off the dissipative part, and we ask: Is that dynamical system a Hamiltonian system, and if so, is it integrable?

In the Schwarzschild spacetime, we show that the system is Hamiltonian and integrable, to linear order in the mass ratio, for generic (but not necessarily all) stable bound orbits. There exist an energy and an angular momentum, being perturbed versions of their counterparts for geodesic motion, which are conserved under the forced motion. We also discuss difficulties associated with establishing analogous results in the Kerr spacetime. This result may be useful for future computational schemes, based on a local Hamiltonian description, for calculating the conservative self-force and its observable effects. It is also relevant to the assumption of the existence of a Hamiltonian for the conservative dynamics for generic orbits in the effective-one-body formalism, to linear order in the mass ratio, but to all orders in the post-Newtonian expansion.

I. INTRODUCTION

Recent years have seen great progress in computing the motion of and gravitational wave signals emitted by point-like objects orbiting massive black holes [1–4], but some key foundational and computational challenges still lie ahead [5]. A sufficiently accurate solution to the gravitational self-force problem will be crucial to the detection and analysis of signals from astrophysical extreme-mass-ratio inspirals by future space-based gravitational wave detectors [6]. Study of the self-force also helps to inform other complementary approaches to the relativistic two-body problem, such as post-Newtonian theory and the effective-one-body formalism [6].

The foundations for computing the first-order self-force acting on a point mass in a curved background spacetime are provided by a result [7, 8] which has been canonized as the ‘MiSaTaQuWa equation’. This is an equation for the effective-one-body formalism [6].

Schemes 2 and 3 have a clear advantage over scheme 1 in being able to describe inspiraling motion over a radiation reaction timescale. Both 2 and 3 reduce to 1 for small deviations from the fiducial geodesic, over short timescales. Scheme 2 is said to arise from 3 via a reduction of order procedure: because the self-forced worldline and the osculating geodesic agree to zeroth order in the mass ratio, the former can be replaced with the latter in calculating the self-force to first order. The relative accuracies and computational merits of 2 and variants of 3 are subtle issues, entangled with formulating and implementing a consistent second-order analog of the MiSaTaQuWa result [11–14], which will not be addressed here.

This paper addresses a formal question concerning the worldline dynamics defined by scheme 2, using only the conservative part of the self-force, turning off the dissipative/radiative part. We ask: Is the resultant dynamical

1 Since the stress energy tensor for an accelerated worldline is not conserved, implementing this scheme requires an ad hoc relaxation of the Lorentz gauge condition.
system, for the worldline degrees of freedom only, an integrable Hamiltonian system, to linear order in the mass ratio?

In the case where the background spacetime is Schwarzschild, we show that this system is indeed a Hamiltonian dynamical system, in the classic sense \[15\]. We also show that it is integrable; in other words, there exist three functions (the rest mass, an energy, and an angular momentum) on the effectively six-dimensional phase space whose values are instantaneously conserved along the system’s trajectories. These results hold to linear order in the mass ratio, for generic stable bound orbits (with some caveats for orbits in the zoom-whirl regime).

We also carry out a partial analysis of the case of the Kerr spacetime, following the same line of reasoning which leads to a successful construction in Schwarzschild. In Kerr, we encounter complications which are associated with orbital resonances \[16\], when the ratio of the frequencies of the radial and polar motions is a rational number. These complications prevent us from drawing definite conclusions about the Kerr case.

There is, however, a heuristic argument which suggests that the motion in Kerr should be integrable and Hamiltonian \[17, 18\]. Namely, the ambiguities in the definition of angular momentum related to the BMS group are associated with the dissipative sector of the linear perturbations, so the conservative sector should admit three independent conserved components of angular momentum \[19\], a sufficient number to make the system integrable. This general picture is consistent with what has been found in the post-Newtonian approximation, where the system is integrable at successive orders \[18\].

The conservative self-force dynamics in Kerr has recently been cast in a Hamiltonian-like formulation in Ref. \[20\]. However, that formulation is not Hamiltonian in the classic sense used here. Specifically, in that formalism, the equations of motion are obtained by differentiating the Hamiltonian with respect to one set of variables while holding a second set of variables fixed, and then taking the two sets of variables to coincide.

The existence of a Hamiltonian system for the conservative dynamics is a foundational assumption in the effective-one-body formalism \[21\], as well as in other related treatments of the relativistic two-body problem, e.g. \[22, 23\]. While the results of Refs. \[22, 23\] make it clear that such a Hamiltonian exists for circular orbits in the extreme-mass-ratio limit (to linear order in the mass ratio, but to all orders in the post-Newtonian expansion), our result confirms the validity of this assumption for generic (non-circular) orbits, in the non-spinning case.

This paper is organized as follows. Our construction relies heavily on the fact that geodesic motion in the Schwarzschild (and Kerr) spacetime is completely integrable, and thus admits a representation in terms of generalized action-angle variables \[17, 26\]. We review relevant properties of these variables in Sec. \[III\] and we review relevant properties of the local conservative self-force in Sec. \[III\]. We develop sufficient conditions for the forced system to be Hamiltonian and integrable in Sec. \[IV\] and we conclude in Sec. \[V\].

## II. GEODESIC MOTION IN KERR AND ACTION-ANGLE VARIABLES

Geodesic motion in a spacetime with metric $g_{\mu\nu}$ is generated by the Hamiltonian

$$H_0(z, p) = \frac{1}{2} g^{\mu\nu}(z)p_\mu p_\nu,$$

(2.1)

where $z^\mu(\lambda)$ are the coordinates of a worldline, and $p_\mu(\lambda)$ are the components of its momentum, together with the canonical symplectic form $\Omega_0 = dz^\mu \wedge dp_\mu$ on the worldline phase space $(z^\mu, p_\mu)$ \[13, 17\]. Hamilton’s equations read

$$\frac{dz^\mu}{d\lambda} = \frac{\partial H_0}{\partial p_\mu}, \quad \frac{dp_\mu}{d\lambda} = -\frac{\partial H_0}{\partial z^\mu},$$

(2.2)

and imply the geodesic equation in affine parameterization, $p^\mu \nabla_\nu p_\nu = 0$. Identifying the affine parameter as $\lambda = \tau/m$, where $\tau$ is the proper time along the worldline, gives the usual expression $p_\mu = mz^\nu \partial z^\nu / \partial \tau$ for the momentum of a particle of mass $m$, and also yields $H_0 = -m^2/2$ on shell.

In the Kerr spacetime, with Boyer-Lindquist coordinates $z^\mu = (t, r, \theta, \phi)$, geodesic motion is completely integrable thanks to the existence of four first integrals of motion. These are the Hamiltonian $H_0$, the energy $E = -\partial_\tau z^{\mu} p_\mu$, the axial angular momentum $L_z = (\partial_\phi) \mu p_\mu$, and the Carter constant $Q = K^{\mu\nu} p_\mu p_\nu$, where $\partial_\phi$ and $\partial_\tau$ are the timelike and axial Killing vectors, and $K^{\mu\nu}$ is the non-trivial Killing tensor.

These four first integrals are independent and in involution, which implies the existence of generalized action-angle variables\(^2\) for bound geodesics in the Kerr geometry \[17, 26\]. These are canonical coordinates $(q^a, J_\alpha) = (q', q^\theta, q^\phi, J_1, J_2, J_3)$ on the worldline phase space, for which the geodesic Hamiltonian $H_0$ depends only on the action variables $J_\alpha$,

$$H_0(z, p) = H_0(J),$$

(2.3)

and not on the angle variables $q^a$. They are obtained from the $(z^\mu, p_\mu)$ coordinates via a canonical transformation

$$q^a = q^a(z^\mu, p_\mu), \quad J_\alpha = J_\alpha(z^\mu, p_\mu),$$

(2.4)

\(^2\) The action angle variables discussed here are associated with the affine parameter $\lambda = \tau/m$ along the worldline; there are also other action-angle coordinates on the phase space associated with Mino time \[27\] and Boyer-Lindquist coordinate time.
so that $\Omega_0 = dx^\mu \wedge dp_\mu = dq_\alpha \wedge dJ_\alpha$. Hamilton’s equations then take the particularly simple form

$$\frac{dq_\alpha}{d\lambda} = \frac{\partial H_0}{\partial J_\alpha} = \omega^\alpha(J),$$

$$\frac{dJ_\alpha}{d\lambda} = -\frac{\partial H_0}{\partial q^\alpha} = 0.$$  \hspace{1cm} (2.5a)

The action variables $J_\alpha$ are all independent constants of motion, and the angle variables $q^\alpha$ all increase linearly, at the constant rates $\omega^\alpha$ known as the fundamental frequencies. The angle variables $q^r$, $q^\theta$, and $q^\phi$ are each periodic with period $2\pi$, while $q^\phi$ has an infinite range. The action variables $J_\alpha$ are functions of the geodesic first integrals $P_\alpha \equiv (H_0, E, L_z, Q)$; in particular, $J_t = -E$ and $J_\phi = L_z$.

In the Schwarzschild limit of the Kerr geometry, both geodesic motion and self-forced motion are confined to a plane, which can be taken without loss of generality to be the equatorial plane $\theta = \pi/2$. We can then ignore the $\theta$-motion, working in the reduced phase space with coordinates $(z^\mu, p_\mu) = (t, r, \phi, p_t, p_r, p_\phi)$. We have the three first integrals $P_\alpha = (H_0, E, L_z)$, and action-angle variables $(q^r, J_\alpha) = (q^r, q^\theta, J_t, J_r, J_\phi)$, defined just as in the general Kerr case.

### III. CONSERVATIVE-SELF-FORCE PERTURBATION TO GEODESIC MOTION

Instead of geodesic motion, we now consider a point mass $m$ with worldline $z^\mu(\lambda)$ experiencing a local linear perturbing force,

$$\frac{dz^\mu}{d\lambda} = p^\mu, \quad p^\nu \nabla_\nu p_\mu = \epsilon F_\mu(z, p),$$

(3.1)

where $\epsilon$ is a small parameter. We are interested in the case where the forcing function $F_\mu(z, p)$ is given by the conservative part of the osculating-geodesic-sourced first-order gravitational self-force in the Kerr spacetime, with the parameter $\epsilon$ being the small mass ratio $m/M$.

The worldline dynamics (3.1) can be re-expressed in terms of the geodesic action-angle variables $(q^\alpha, J_\alpha)$ as

$$\frac{dq^\alpha}{d\lambda} = \omega^\alpha(J) + \epsilon f^\alpha(q, J),$$

$$\frac{dJ_\alpha}{d\lambda} = \epsilon F_\alpha(q, J),$$

(3.2a)

(3.2b)

following Ref. [17]. Here we use the same phase space coordinate transformation (2.3) as for geodesic motion to obtain Eqs. (3.2) from Eqs. (3.1). The forcing functions $f^\alpha(q, J)$ and $F_\alpha(q, J)$ are determined from the self-force components $F_\mu(z, p)$ via $f^\alpha = (\partial q^\alpha / \partial p_\mu)_z F_\mu$ and $F_\alpha = (\partial J_\alpha / \partial p_\mu)_z F_\mu$. These functions have the important property that they are independent of the angle variables $q^r$ and $q^\phi$, because of the symmetries of the Kerr spacetime. Thus, they can written as functions of $q^r$, $q^\theta$ and the four variables $J_\alpha$ [17]:

$$f^\alpha(q, J) = f^\alpha(q^r, q^\theta, J),$$

$$F_\alpha(q, J) = F_\alpha(q^r, q^\theta, J).$$

(3.3a)

(3.3b)

In the Schwarzschild case, these functions depend only on $q^r$ and the three $J_\alpha$.

The forcing functions $f^\alpha$ and $F_\alpha$ are periodic functions of $q^r$ and of $q^\theta$, each with period $2\pi$. They can thus be expanded as Fourier series in $q^r$ and $q^\theta$, according to

$$F_\alpha(q^r, q^\theta, J) = \sum_{k_r, k_\theta} \hat{F}_\alpha(k_r, k_\theta, J) e^{ik_r q^r + ik_\theta q^\theta},$$

(3.4)

and similarly for $f^\alpha$. As shown by Mino [27], the $(0,0)$ Fourier mode of each $F_\alpha$ vanishes,

$$\hat{F}_\alpha(0,0, J) = \frac{1}{(2\pi)^2} \int_0^{2\pi} dq^r \int_0^{2\pi} dq^\theta F_\alpha(q^r, q^\theta, J) = 0,$$

(3.5)

due to reflection properties of Kerr geodesics and to the time-reversal symmetry of the conservative self-force [17, 27].

In the Schwarzschild case, we lose the dependence on the $\theta$-motion. Equations (3.3a) and (3.3b) are replaced by

$$F_\alpha(q^r, J) = \sum_{k_r} \hat{F}_\alpha(k_r, J) e^{ik_r q^r},$$

(3.6)

and similarly with $F_\alpha$ replaced by $f^\alpha$. Equation (3.5) becomes

$$\hat{F}_\alpha(0, J) = \frac{1}{2\pi} \int_0^{2\pi} dq^r F_\alpha(q^r, J) = 0.$$

(3.7)

Recalling that the forcing functions $F_\alpha$ give the rates of change of the action variables $J_\alpha$, Eqs. (3.6) and (3.7) express the fact that the conservative first-order self-force causes no net change in the geodesic first integrals, when the force is evaluated along a geodesic and suitably averaged [27]. In the Schwarzschild case (3.7), the averaging is an orbital average or time average over one period of radial motion. In the Kerr case (3.6), the averaging is over the $(q^r, q^\theta)$ torus in phase space, which is equivalent to a time average only over an infinite time and only for non-resonant orbits [16, 17, 28].

### IV. IS THE PERTURBED SYSTEM HAMILTONIAN AND INTEGRABLE?

The perturbed system (3.2) will be Hamiltonian and integrable, to linear order in $\epsilon$, if there exist new phase space coordinates $(q^\alpha, J_\alpha)$ and a new Hamiltonian function $\hat{H}(J)$ for which Eqs. (3.2) are equivalent to

$$\frac{dq^\alpha}{d\lambda} = \frac{\partial \hat{H}(J)}{\partial J_\alpha} + O(\epsilon^2), \quad \frac{dJ_\alpha}{d\lambda} = O(\epsilon^2).$$

(4.1)
Without loss of generality, we can express the new coordinates as linear perturbations of the geodesic action-angle coordinates \((q^\alpha, J_\alpha)\):

\[
\begin{align*}
\tilde{q}^\alpha(q, J) &= q^\alpha + \epsilon\chi^\alpha(q, J), \quad (4.2a) \\
\tilde{J}_\alpha(q, J) &= J_\alpha + \epsilon\zeta_\alpha(q, J), \quad (4.2b)
\end{align*}
\]

for some functions \(\chi^\alpha\) and \(\zeta_\alpha\) to be determined. Note that \((4.2)\) is not assumed to be a canonical transformation. Similarly we can express the new Hamiltonian as

\[
\tilde{H}(\tilde{J}) = H_0(\tilde{J}) + \epsilon H_1(\tilde{J}), \quad (4.3)
\]

where \(H_0\) is the geodesic Hamiltonian function, for some function \(H_1(\tilde{J})\) to be determined.

Combining Eqs. \((4.1), (4.2)\) and \((4.3)\) now yields that Eqs. \((4.1)\) will be equivalent to Eqs. \((3.2)\) to linear order in \(\epsilon\) if

\[
\begin{align*}
f^\alpha(q, J) &= -\omega^\beta \frac{\partial \chi^\alpha}{\partial q^\beta} + \frac{\partial \omega^\alpha}{\partial J_\beta} \zeta_\beta + \frac{\partial H_1}{\partial J_\alpha}, \quad (4.4a) \\
F_\alpha(q, J) &= -\omega^\beta \frac{\partial \zeta_\alpha}{\partial q^\beta}, \quad (4.4b)
\end{align*}
\]

where \(\omega^\alpha = \omega^\alpha(J)\) are the geodesic fundamental frequencies \([2.5]\). Thus, the conservative-self-force dynamics \((3.2)\) will be Hamiltonian and integrable if there exist functions \(\chi^\alpha(q, J), \zeta_\alpha(q, J),\) and \(H_1(J)\) satisfying Eqs. \((4.4a)\) and \((4.4b)\).

In light of Eqs. \((3.2)\), it is natural to consider solutions for \(\chi^\alpha\) and \(\zeta_\alpha\), which, like \(f^\alpha\) and \(F_\alpha\), are independent of \(q^r\) and \(q^\theta\), and which are periodic functions of \(q^r\) and \(q^\theta\) (or of just \(q^\theta\) in Schwarzschild). We can then decompose all of these functions into discrete Fourier series for the \(q^r\) and \(q^\theta\) dependence, just as for \(F_\alpha\) in Eq. \((3.1)\) [or Eq. \((3.3)\)]. This defines Fourier mode amplitudes \(\tilde{f}^\alpha, \tilde{F}_\alpha, \tilde{\chi}^\alpha,\) and \(\tilde{\zeta}_\alpha\) which are functions of the two integers \(k_r\) and \(k_\theta\) [or just \(k_r\)] and all of the action variables \(J_\alpha\).

We then have the following Fourier transforms of Eqs. \((4.1a)\) and \((4.1b)\):

\[
\begin{align*}
\tilde{f}^\alpha &= -i(\omega \cdot k)\tilde{\chi}^\alpha + \frac{\partial \omega^\alpha}{\partial J_\beta} \tilde{\zeta}_\beta + \delta_{k_r,0} \delta_{k_\theta,0} \frac{\partial H_1}{\partial J_\alpha}, \quad (4.5a) \\
\tilde{F}_\alpha &= -i(\omega \cdot k)\tilde{\zeta}_\alpha, \quad (4.5b)
\end{align*}
\]

where

\[
(\omega \cdot k) = \begin{cases} 
\omega^r k_r + \omega^\theta k_\theta & \text{Kerr} \\
\omega^r & \text{Schwarzschild}
\end{cases} \quad (4.6)
\]

and with \(\delta_{k_r,0} \rightarrow 1\) in Schwarzschild. If we restrict attention to Fourier modes for which \((\omega \cdot k) \neq 0\), then Eqs. \((4.5a)\) and \((4.5b)\) admit the simple solutions

\[
\tilde{\zeta}_\alpha = \frac{i\tilde{F}_\alpha}{(\omega \cdot k)}, \quad \tilde{\chi}^\alpha = \frac{i}{(\omega \cdot k)} \left( \tilde{f}^\alpha - \frac{\partial \omega^\alpha}{\partial J_\beta} \tilde{\zeta}_\beta \right). \quad (4.7)
\]

In the general Kerr case, the quantity \(\omega \cdot k = \omega^r k_r + \omega^\theta k_\theta\) can vanish at locations in phase space where \(\omega^r / \omega^\theta\) is a rational number, corresponding to an orbital resonance in the \(r\) and \(\theta\) motions \([16]\). The solutions \((4.7)\) are clearly not valid in such cases, and so our analysis does not allow us to draw any definite conclusions about the Kerr case.

For stable bound orbits in Schwarzschild, the quantity \(\omega \cdot k = \omega^r k_r\) vanishes only when \(k_r = 0\), since \(\omega^r = 0\) occurs only in the limit of unbound or unstable orbits. Equations \((4.7)\) thus provide valid solutions for all Fourier modes of \(\chi^\alpha\) and \(\zeta_\alpha\), except for the \(k_r = 0\) modes. Given the fact \((3.7)\) that \(\tilde{F}_\alpha(0, J) = 0\), we see that a separate solution to Eqs. \((4.5a)\) and \((4.5b)\) for the case \(k_r = 0\) is given by

\[
\tilde{\zeta}_\alpha(0, J) = \left( \frac{\partial \omega^\beta}{\partial J_\alpha} \right)^{-1} \tilde{f}^\beta(0, J), \quad H_1 = 0, \quad (4.8)
\]

[with \(\chi^\alpha(0, J) = 0\) unconstrained], provided that the matrix \(\partial \omega^\beta / \partial J_\alpha\) is invertible. It follows from the results of Ref. \([29]\) that \(\partial \omega^\beta / \partial J_\alpha\) is invertible for all stable bound geodesics, except for those along the singular curve associated with isofrequency pairing of Schwarzschild geodesics in the zoom-whirl regime (and those along the separatrix defining the boundary of stable orbits); see Figure 1 of Ref. \([29]\). Thus, we have constructed a solution of Eqs. \((4.4a)\) and \((4.4b)\), and so the perturbed motion is Hamiltonian and integrable.

V. CONCLUSION

We have shown that the local first-order conservative self-force dynamics in the Schwarzschild spacetime is an integrable Hamiltonian system, to linear order in the mass ratio, for generic stable bound orbits outside the zoom-whirl regime (more specifically, for all orbits to the right of the “singular curve” in Figure 1 of Ref. \([29]\). The Hamiltonian system is defined by Eqs. \((4.1)\), with the coordinates \((\tilde{q}^\alpha, \tilde{J}_\alpha)\) defined in terms of the geodesic action-angle coordinates by Eqs. \((4.2)\), and with the Fourier modes of the functions \(\chi^\alpha\) and \(\zeta_\alpha\) given by Eqs. \((4.7)\) and \((4.8)\). The quantities \(-\tilde{J}_r\) and \(\tilde{J}_\phi\) are well-defined functions on the worldline phase space, which are perturbed versions of the geodesic energy \(E\) and angular momentum \(L_z\), which are instantaneously conserved to linear order under the conservative-self-forced motion.

Finally, we remark that the obstacles encountered by our construction in the general Kerr case do not show that the system is not Hamiltonian or integrable in Kerr.
