Quantum propagation for Berezin-Toeplitz operators

Laurent Charles, Yohann Le Floch

February 8, 2021

Abstract

We describe the asymptotic behaviour of the quantum propagator generated by a Berezin-Toeplitz operator with real-valued principal symbol. We also give precise asymptotics for smoothed spectral projectors associated with the operator in the autonomous case; this leads us to introducing quantum states associated with immersed Lagrangian submanifolds. These descriptions involve geometric quantities of two origins, coming from lifts of the Hamiltonian flow to the prequantum bundle and the canonical bundle respectively. The latter are the main contribution of this article and are connected to the Maslov indices appearing in trace formulas, as will be explained in a forthcoming paper.

1 Introduction

Let $M^n$ be a compact complex manifold endowed with two Hermitian holomorphic line bundles $L$ and $L'$. We assume that $L$ is positive, meaning that the curvature of its Chern connection is $\frac{1}{i}\omega$ with $\omega \in \Omega^2(M, \mathbb{R}) \cap \Omega^{(1,1)}(M)$ positive. For any positive integer $k$, let $\mathcal{H}_k$ be the space of holomorphic sections of $L^k \otimes L'$. The scalar product of sections of $L^k \otimes L'$ is defined as the integral of the pointwise scalar product against the Liouville volume form $\mu = \omega^n$.

Given a function $f \in C^\infty(M)$, the Berezin-Toeplitz operator $T_k(f)$ is the endomorphism of $\mathcal{H}_k$ such that

$$\langle T_k(f)u, v \rangle = \langle fu, v \rangle, \quad \forall u, v \in \mathcal{H}_k.$$
We are interested in the semi-classical limit $k \to +\infty$ and the techniques we use allow to consider more general families $T := (T_k(f(\cdot,k)))$ where the multiplicator itself depends on $k$ and has an expansion of the form $f(\cdot,k) = f_0 + k^{-1} f_1 + \ldots$ with coefficients $f_\ell \in \mathcal{C}^\infty(M)$. We will also consider time-dependent sequences $f(\cdot, t, k)$ with an expansion with time-dependent coefficients.

We call the family $T$ a Toeplitz operator, $f_0$ its principal symbol and $f_1 + \frac{i}{2} \Delta f_0$ its subprincipal symbol. Here $\Delta$ is the holomorphic Laplacian associated with the Kähler form $\omega$, so $\Delta = \sum h^{ij} \partial_{z_i} \partial_{\bar{z}_j}$ when $\omega = i \sum h^{ij} dz_i \wedge d\bar{z}_j$. The reason why we introduce this subprincipal symbol is merely that it simplifies the subleading calculus.

Typically, if $T$ and $S$ are two Toeplitz operators with principal symbols $f$ and $g$, then $TS$ and $ik[T, S]$ are Toeplitz operators with principal symbols $fg$ and the Poisson bracket $\{f, g\}$ with respect to $\omega$ [3, 1]. If now $T$ and $S$ have identically zero subprincipal symbols, then the subprincipal symbols of $TS$ and $ik[T, S]$ are $\frac{1}{2i} \{f, g\}$ and $-\omega_1(X,Y)$ respectively [8], where $X, Y$ are the Hamiltonian vector fields of $f$ and $g$ and $\omega_1$ is the real two-form given by $\omega_1 = i(\Theta_{L'} - \frac{1}{2} \Theta_K)$, with $\Theta_{L'}, \Theta_K$ the curvatures of the Chern connections of $L'$ and the canonical bundle $K$.

1.1 The quantum propagator

It is a well-known result that the solution of the Schrödinger equation for a pseudo-differential operator is a Fourier integral operator associated with the Hamiltonian flow of its principal symbol. Our first result is the Toeplitz analogue of this fact. Consider a time-dependent Toeplitz operator $(T_{k,t})$ with principal symbol $(H_t)$ and subprincipal symbol $(H^{\text{sub}}_t)$. The quantum propagator generated by $T_{k,t}$ is the smooth path $(U_{k,t}, t \in \mathbb{R})$ of (unitary in case $T_{k,t}$ is self-adjoint) maps of $\mathcal{H}_k$ satisfying the Schrödinger equation

$$(ik)^{-1} \frac{d}{dt} U_{k,t} + T_{k,t} U_{k,t} = 0, \quad U_{k,0} = \text{id}. \quad (1)$$

Our goal is to describe the Schwartz kernel of $U_{k,t}$, which by definition is

$$U_{k,t}(x,y) = \sum_{i=1}^{d_k} (U_{k,t} \psi_i)(x) \otimes \overline{\psi}_i(y) \in (L^k \otimes L')_x \otimes (\overline{L}^k \otimes \overline{L}')_y$$

where $d_k = \dim \mathcal{H}_k$ and $(\psi_i)$ is any orthonormal basis of $\mathcal{H}_k$. In the sequel, we will view $U_{k,t}(x,y)$ as a map from $(L^k \otimes L')_y$ to $(L^k \otimes L')_x$ using the scalar product of $(L^k \otimes L')_y$.
As we will see, when the principal symbol \( (H_t) \) is real, this Schwartz kernel is concentrated on the graph of the Hamiltonian flow \( \phi_t \) of \( H_t \). Here the symplectic form \( \omega \) is \( i \) times the curvature of \( L \), and the Hamiltonian vector field \( X_t \) is such that

\[
\omega(X_t, \cdot) + dH_t = 0. \tag{2}
\]

To describe the asymptotic behavior of \( U_{k,t}(\phi_t(x), x) \), we need to introduce two lifts of \( \phi_t \), the first one to \( L \) and the second one to the canonical bundle \( K \) of \( M \). The relevant structures on \( L \) will be its metric and its connection, which is generally called the prequantum structure.

**Parallel transport and prequantum lift**

If \( A \to M \) is a Hermitian line bundle endowed with a connection \( \nabla \), the *parallel transport* in \( A \) along a path \( \gamma : [0, \tau] \to M \) is a unitary map

\[
\mathcal{T}(A, \gamma) : A_{\gamma(0)} \to A_{\gamma(\tau)}
\]

which can be computed as follows: if \( u \) is a frame of \( \gamma^\ast A \), then

\[
\mathcal{T}(A, \gamma) u(0) = \exp(i \int_0^\tau \alpha) u(\tau),
\]

where \( \alpha \in \Omega^1([0, \tau], \mathbb{R}) \) is the connection one-form defined in terms of the covariant derivative of \( u \) by \( \nabla u = -i \alpha \otimes u \). In particular we can lift by parallel transport the Hamiltonian flow \( \phi_t \). We set \( \mathcal{T}_t^A(x) := \mathcal{T}(A, \phi_{[0,t]}(x)) : A_x \to A_{\phi_t(x)} \).

The *prequantum lift* of the Hamiltonian flow \( \phi_t \) to \( L \) is defined by

\[
\phi_t^L(x) = e^{\frac{i}{\hbar} \int_0^t H_t(\phi_r(x)) \, dr} \mathcal{T}_t^L(x). \tag{3}
\]

This lift has an interest independently of Toeplitz operators: by the Kostant-Souriau theory, \( \phi_t^L \) is the unique (up to a phase) lift of \( \phi_t \) which preserves the metric and the connection of \( L \). Furthermore, if \( x \) belongs to a contractible periodic trajectory with period \( T \), so that we can define the action \( A(x, T) \in \mathbb{R} \), then \( \phi_T^L(x) : L_x \to L_x \) is the multiplication by \( \exp(iA(x, T)) \).

In our results, \( \phi_t^L \) will appear to the power \( k \) with some corrections involving the subprincipal data \( L' \) and \( H_t^{\text{sub}} \), more precisely we will see

\[
e^{\frac{i}{\hbar} \int_0^t H_t^{\text{sub}}(\phi_r(x)) \, dr} \phi_t^L(x)^{\otimes k} \mathcal{T}_t^{L'}(x) : (L^k \otimes L')_x \to (L^k \otimes L')_{\phi_t(x)}. \tag{4}
\]

So we merely replace \( L \) by \( L^k \otimes L' \) and \( H_t \) by \( kH_t + H_t^{\text{sub}} \) in (3).
Holomorphic determinant and lift to the canonical bundle

The second ingredient we need is an invariant of the complex and symplectic structures together. If \( g : S \to S' \) is a linear symplectomorphism between two \( 2n \)-dimensional symplectic vector spaces both endowed with linear complex structures, we define an isomorphism \( K(g) : K(S) \to K(S') \) between the canonical lines \( K(S) = \wedge^{n,0}S^*, \ K(S') = \wedge^{n,0}(S')^* \) characterized by

\[
K(g)(\alpha)(g_*u) = \alpha(u), \quad \forall \alpha \in K(S), u \in \wedge^n S.
\]

Equivalently, if \( E \) and \( E' \) are the \((1,0)\)-spaces of \( S \) and \( S' \) respectively, we have decompositions

\[
S \otimes \mathbb{C} = E \oplus E', \quad S' \otimes \mathbb{C} = E' \oplus E', \quad g \otimes \text{id}_\mathbb{C} = \begin{pmatrix} g^{1,0} & * \\ * & * \end{pmatrix}
\]

with \( g^{1,0} : E \to E' \). Then \( K(g) \) is the dual map of \( \det g^{1,0} : \wedge^n E \to \wedge^n E' \) in the sense that \( K(g)(\alpha)((\det g^{1,0})u) = \alpha(u) \) for any \( \alpha \in K(S) \) and \( u \in \wedge^n E \).

This holomorphic determinant has a nice structure in terms of the polar decomposition of linear symplectic maps. When \( S = S' = \mathbb{R}^{2n} \) with its usual complex structure \( j \), \( g = g_1g_2 \) where \( g_1 \) and \( g_2 \) are both symplectic, \( g_1 \) commutes with \( j \), and \( g_2 \) is symmetric positive definite. Then \( K(g) \) is a complex number whose inverse is

\[
\det \mathbb{C} g^{1,0} = \left( \prod_{i=1}^{n} \frac{\lambda_i + \lambda_i^{-1}}{2} \right) \det \mathbb{C} g_1
\]

with \( 0 < \lambda_1 \leq \ldots \leq \lambda_n < 1 < \lambda_n^{-1} \leq \ldots \leq \lambda_1^{-1} \) the eigenvalues of \( g_2 \), and \( \det \mathbb{C} g_1 \) the determinant of \( g_1 \) viewed as a \( \mathbb{C} \)-linear endomorphism of \( \mathbb{C}^n \). Indeed, \( \det \mathbb{C} g^{1,0} = \det \mathbb{C} g_2^{1,0} \det \mathbb{C} g_1 \) and one readily computes \( \det \mathbb{C} g_2^{1,0} \) using the diagonalization of \( g_2 \) in an orthonormal basis \((e_1, \ldots, e_n, je_1, \ldots, je_n)\) with \( g_2e_\ell = \lambda_\ell e_\ell \) and \( g_2je_\ell = \lambda_\ell^{-1} je_\ell \). This formula generalizes for \( (S, j) \neq (S', j') \), with now linear symplectic maps \( g_1 : S \to S' \) and \( g_2 : S \to S \), where \( g_1 \circ j = j' \circ g_1 \), and \( g_2 \) is positive definite for the Euclidean structure \( \omega(\cdot, \cdot) \) of \( S \). The complex determinant of \( g_1 \) may be viewed as a map from \( \det \mathbb{C}(S, j) \) to \( \det \mathbb{C}(S', j') \) or equivalently from \( \wedge^{top}E \) to \( \wedge^{top}E' \).

This definition provides us with a lift \( D_t \) of the Hamiltonian flow \( \phi_t \) to the canonical bundle \( K = \wedge^{(n,0)}T^*M \), defined by

\[
D_t(x) = K(T_x \phi_t) : K_x \to K_{\phi_t(x)}.
\]

We have another lift of \( \phi_t \) to the canonical bundle which is the parallel transport \( T_t^K \). Define the complex number \( \rho_t(x) \) such that \( D_t(x) = \rho_t(x) T_t^K(x) \).
The result

**Theorem 1.1.** Let \((U_{k,t})\) be the quantum propagator of a time-dependent Toeplitz operator \((T_{k,t})\) with real principal symbol. Then for any \(t \in \mathbb{R}\) and \(x \in M\),

\[
U_{k,t}(\phi_t(x), x) = \left(\frac{k}{2\pi}\right)^n \left[\rho_t(x)\right]^{\frac{1}{2}} e^{\frac{i}{2} \int_0^t H_{r_{\phi_t(x)}}(x) \, dr} \left[\phi_t^L(x)\right]^\otimes k \otimes T_{t'}^L(x) + O(k^{n-1})
\]

(8)

where \(\phi_t\) is the Hamiltonian flow of the principal symbol \(H_t\), \(\phi_t^L\) and \(T_{t'}^L\) are its prequantum and parallel transport lifts, \(H_{r_{\phi_t(x)}}\) is the subprincipal symbol and \((\rho_t)^{1/2}\) is the continuous square root equal to 1 at \(t = 0\) of the function \(\rho_t\) such that \(\mathcal{D}_t = \rho_t T_t^K\) with \(\mathcal{D}_t(x) = K(T_x \phi_t)\).

If \(y \in M\) is different from \(\phi_t(x)\), then \(U_{k,t}(y, x) = O(k^{-N})\) for all \(N\).

The first part of the result has an alternative formulation when \(M\) has a half-form bundle, that is a line bundle \(\delta\) and an isomorphism between \(\delta^2\) and the canonical bundle \(K\). Introducing the line bundle \(L_1\) such that \(L' = L_1 \otimes \delta\) and using that \(T_{t'}^L = T_{t'}^{L_1} \otimes T_0^\delta\), we obtain

\[
U_{k,t}(\phi_t(x), x) \sim \left(\frac{k}{2\pi}\right)^n e^{\frac{i}{2} \int_0^t H_{r_{\phi_t(x)}}(x) \, dr} \left[\phi_t^L(x)\right]^\otimes k \otimes T_{t'}^{L_1}(x) \otimes \left[D_t(x)\right]^{\frac{1}{2}}
\]

where \([D_t(x)]^{1/2} : \delta_x \to \delta_{\phi_t(x)}\) is the continuous square root of \(D_t(x)\) equal to 1 at \(t = 0\). Observe that to write this equation, it is sufficient to define \(\delta\) on the trajectory \(t \to \phi_t(x)\), which is always possible.

In the above statement, we focused on the geometrical description of the leading order term, because it is the real novelty. The complete result, Theorem 6.3, too long for the introduction, is that \(U_{k,t}(\phi_t(x), x)\) has a full asymptotic expansion in integral powers of \(k^{-1}\) and we also have a uniform description with respect to \(x\), \(y\) and \(t\) on compact regions. Such a uniform description is not obvious because the asymptotic behavior of \(U_{k,t}(y, x)\) is completely different whether \(y = \phi_t(x)\) or not. We actually show that the Schwartz kernel of \(U_{k,t}\) is a Lagrangian state in the sense of [6], associated with the graph of \(\phi_t\).

In the Appendix, we investigate an explicit example in which the Hamiltonian flow does not preserve the complex structure, and verify the validity of the above theorem for the kernel of the propagator on the graph of this flow.
1.2 Smoothed spectral projector

Our second result is the asymptotic description of the Schwartz kernel of \( f(k(E - T_k)) \) where \((T_k)\) is a self-adjoint Toeplitz operator, \(E\) is a regular value of the principal symbol \(H\) of \((T_k)\) and \(f \in C^\infty(\mathbb{R}, \mathbb{R})\) is a smooth function having a compactly supported Fourier transform. For a function \(g : \mathbb{R} \to \mathbb{R},\) \(g(T_k)\) is merely defined as \(\sum_{\lambda \in \text{sp}(T_k)} g(\lambda) \Pi_\lambda\) where for each eigenvalue \(\lambda\) of \(T_k,\) \(\Pi_\lambda\) is the orthogonal projector onto the corresponding eigenspace. For \(g\) smooth, \(g(T_k)\) is itself a Toeplitz operator with principal symbol \(g \circ H\) and so its Schwartz kernel is concentrated on the diagonal; more precisely

\[
g(T_k)(x, x) = \left(\frac{k}{2\pi}\right)^n g(H(x)) + \mathcal{O}(k^{n-1}),
g(T_k)(x, y) = \mathcal{O}(k^{-N}), \quad \forall N \quad \text{when } x \neq y.
\]

In the rest of the paper we will work with a function \(g\) depending on \(k\) in the very specific way \(g(\tau) = f(k(\tau - E))\), which we interpret as a focus at scale \(k^{-1}\) around \(E\). For instance, for \(f\) the characteristic function of a subset \(A\) of \(\mathbb{R},\) \(f(k(\cdot - E))\) is the characteristic function of \(E + k^{-1}A\). However, we will only consider very regular functions \(f\), having a smooth compactly supported Fourier transform \(\hat{f}\).

Our result is that the Schwartz kernel of \(f(k(E - T_k))\) is a Lagrangian state associated with the Lagrangian immersion

\[
j_E : \mathbb{R} \times H^{-1}(E) \to M^2, \quad (t, x) \mapsto (\phi_t(x), x).
\]

Here \(\phi_t\) is the flow of the autonomous Hamiltonian \(H\). It is important to note that \(j_E\) is not injective and not proper in general. However only the times \(t\) in the support of the Fourier transform of \(f\) matter, so we will work with the restriction of \(j_E\) to a compact subset. Still, it is possible for \(j_E\) to have multiple points because of the periodic trajectories.

The description of the Schwartz kernel on the image of \(j_E\) will be in terms of the parallel transport lift of \(\phi_t\) to \(L\) and \(L'\) as introduced above and a lift \(D'_t\) to the canonical bundle of the restriction of \(\phi_t\) to the energy level set \(H^{-1}(E),\) defined as follows.

First since \(E\) is regular, for any \(x \in H^{-1}(E)\), the Hamiltonian vector field \(X\) of \(H\) is not zero at \(x\). Second, \(H\) being time-independent, \(T_x\phi_t\) sends \(X_x\) into \(X_{\phi_t(x)}\), so it induces a symplectic map from \(T_xH^{-1}(E)/\mathbb{R}X_x\) into \(T_{\phi_t(x)}H^{-1}(E)/\mathbb{R}X_{\phi_t(x)}\). In the case \(x\) is periodic with period \(t\), this map is the tangent linear map to the Poincaré section map.
For any \( x \in H^{-1}(E) \), write \( T_xM = F_x \oplus G_x \) where \( F_x \) is the subspace spanned by \( X_x \) and \( j_x X_x \) and \( G_x \) is its symplectic orthogonal. Observe that \( T_x H^{-1}(E) = G_x \oplus \mathbb{R} X_x \) so that \( G_x = T_x H^{-1}(E)/\mathbb{R} X_x \). Furthermore, both \( F_x \) and \( G_x \) are symplectic subspaces preserved by \( j_x \), so \( K_x \simeq K(F_x) \otimes K(G_x) \). Then we define

\[
\mathcal{D}'_t(x) : K_x \to K_{\hat{\phi}_t(x)}
\]

as the tensor product of the following maps:

1. \( K(F_x) \to K(F_{\hat{\phi}_t(x)}) \), \( \lambda \mapsto 2\|X_x\|^{-2} \lambda' \) where \( \lambda, \lambda' \) are normalised by \( \lambda(X_x) = \lambda'(X_{\hat{\phi}_t(x)}) = 1 \),

2. \( K(\psi) : K(G_x) \to K(G_{\hat{\phi}_t(x)}) \) with \( \psi \) the symplectomorphism

\[
\psi : G_x \simeq T_x H^{-1}(E)/\mathbb{R} X_x \xrightarrow{T_{\phi_t}} T_{\phi_t(x)} H^{-1}(E)/\mathbb{R} X_{\hat{\phi}_t(x)} \simeq G_{\hat{\phi}_t(x)}.
\]

In the particular case where \( T_x \phi_t \) sends \( (jX)_x \) into \( (jX)_{\phi_t(x)} \), one checks that \( \mathcal{D}_t(x) = \|X_x\|^{-2} \mathcal{D}'_t(x) \). Otherwise, there does not seem to be any simple relation between \( \mathcal{D}_t(x) \) and \( \mathcal{D}'_t(x) \).

Exactly as we did for \( \mathcal{D}_t \), we define \( \rho'_t(x) \) as the complex number such that

\[
\mathcal{D}'_t(x) = \rho'_t(x) T^K_t(x).
\]

We denote by \( [\rho'_t(x)]^{1/2} \) the continuous square root equal to \( \sqrt{2}\|X_x\|^{-1} \) at \( t = 0 \).

**Theorem 1.2.** For any self-adjoint Toeplitz operator \( (T_k) \) and regular value \( E \) of its principal symbol \( H \), we have for any \( x, y \in H^{-1}(E) \),

\[
f(k(E - T_k))(y, x) = \left( \frac{k}{2\pi} \right)^{n-\frac{1}{2}} \times \sum_{\substack{t \in \text{Supp} f, \ \phi_t(x) = y}} \hat{f}(t) \left[ \rho'_t(x) \right]^{\frac{1}{2}} e^{\frac{i}{2} \int_0^t H_{\text{sub}}(\phi_r(x)) \ dr} \left[ \mathcal{T}^{L_1}(x) \right] \otimes \mathcal{T}^{L_1}(x) + \mathcal{O}(k^{n-\frac{3}{2}}).
\]

Furthermore, for any \( (x, y) \in M^2 \) not belonging to \( j_E(\text{Supp} f \times H^{-1}(E)) \), we have \( f(k(E - T_k))(x, y) = \mathcal{O}(k^{-\infty}) \).

As in Theorem 1.1, in the case \( M \) has a half-form bundle \( \delta \), we can write \( L' = L_1 \otimes \delta \) and replace the sum above by

\[
\sum_{\substack{t \in \text{Supp} \hat{f}, \ \phi_t(x) = y}} \hat{f}(t) e^{\frac{i}{2} \int_0^t H_{\text{sub}}(\phi_r(x)) \ dr} \left[ \mathcal{T}^{L_1}(x) \right] \otimes \mathcal{T}^{L_1}(x) \otimes [\mathcal{D}'_t(x)]^{\frac{1}{2}}
\]
where \( [\mathcal{D}^t_t(x)]^{1/2} : \delta_x \to \delta_{\phi_t(x)} \) is continuous and equal to \( \|X_x\|^{-1} \text{id}_{L_x} \) at \( t = 0 \).

Furthermore, we will give a uniform description with respect to \((x, y)\) of the Schwartz kernel of \( f(k(E - T_k)) \) by showing it is a Lagrangian state associated with the Lagrangian immersion \( j_E \).

### 1.3 Discussion

Let us explain more the structure of the Lagrangian states appearing in the previous results. Roughly, a Lagrangian state of \( M \) is a family \( (\Psi_k \in \mathcal{H}_k, k \in \mathbb{N}) \) which is \( \mathcal{O}(k^{-\infty}) \) outside a Lagrangian submanifold \( \Gamma \) of \( M \) and which has an asymptotic expansion at any point \( x \in \Gamma \) of the form

\[
\Psi_k(x) = k^m [t(x)]^\otimes k \left( a_0(x) + k^{-1} a_1(x) + \ldots \right)
\]

where \( m \) is some nonnegative integer, \( t(x) \in L_x \) has norm one, and the coefficients \( a_0(x), a_1(x), \ldots \) belong to \( L'_x \). We can think of \( [t(x)]^k \) as an oscillatory factor and \( k^m \sum k^{-\ell} a_\ell(x) \) as an amplitude. Furthermore, \( t(x) \) and the \( a_\ell(x) \) all depend smoothly on \( x \) so that they define sections of \( L \) and \( L' \) respectively over \( \Gamma \). The section \( t \) has the important property to be flat.

Regarding the leading order term \( a_0(x) \) of the amplitude, it is often useful to think about it as a product \( t_1(x) \otimes \nu(x) \) where \( t_1(x) \in (L_1)_x \) and \( \nu(x) \in \delta_x \). Here \( \delta \) is a half-form bundle, which can be introduced at least locally, and \( L' = L_1 \otimes \delta \). Then \( [t(x)]^\otimes k \otimes t_1(x) \) may be viewed as a deformation of \( [t(x)]^\otimes k \), whereas \( \nu(x) \) is a square root of a volume element of \( \Gamma \). Indeed, \( \Gamma \) being Lagrangian, there is a natural pairing between the restriction of the canonical bundle to \( \Gamma \) and the determinant bundle \( \text{det} TT \otimes \mathcal{C} \).

In our results, the Lagrangian states, which are Schwartz kernels of operators, are defined on \( M^2 \), with the prequantum bundle \( L \boxtimes \overline{L} \). Here, the symplectic and prequantum structures are such that the graphs of symplectomorphisms are Lagrangian submanifolds and their prequantum lifts define flat sections. In Theorem 1.1, the Schwartz kernel of the quantum propagator is defined as a Lagrangian state associated with the graph of the Hamiltonian flow and its prequantum lift. As was already noticed, the prequantum lift appears with correction terms \( \exp(i \int_0^t H^{\text{sub}}(\phi_r(x)) \, dr) \) and \( T^{L_1}_t(x) \), which are the contributions of the corrections \( H^{\text{sub}} \) to \( H \) and \( L_1 \) to \( L \). Then the last term \( D^\frac{1}{2}_t \) is merely the square root of the image of the Liouville volume form by the map \( M \to \text{graph} \phi_t \) sending \( x \) into \( (\phi_t(x), x) \).

The relation between Theorems 1.1 and 1.2 relies on the time/energy duality. Roughly, for a time-independent operator \( \hat{H} \), we pass from the
quantum propagator \((\exp(-ih^{-1}t\hat{H}), \ t \in \mathbb{R})\) to the smoothed spectral projector \((f(h^{-1}(\hat{H} - E)), \ E \in \mathbb{R})\), by multiplying by \(\hat{f}(t)\) and then doing a partial \(h\)-Fourier transform with respect to the variables \(t, E\) (here \(k\) plays the part of \(h^{-1}\)). In the microlocal point of view, the variables \(t\) and \(E\) are equivalent and we can view the quantum propagator and the spectral projector as two facets of the same object.

In our results, this duality is expressed by the fact that the graph of \(\phi_t\) and the Lagrangian immersion \(j_E\) are obtained in a symmetric way from the Lagrangian submanifold
\[
\tilde{\Gamma} = \{(t, H(x), \phi_t(x), x)/x \in M, t \in \mathbb{R}\}
\]
of \(T^*\mathbb{R} \times M \times M^-\). Indeed, the graph of \(\phi_t\) and the image of \(j_E\) are the projections onto \(M^2\) of the slices
\[
\tilde{\Gamma}_t = \tilde{\Gamma} \cap (\{t\} \times \mathbb{R} \times M^2), \quad \tilde{\Gamma}^E = \tilde{\Gamma} \cap (\mathbb{R} \times \{E\} \times M^2).
\]
The prequantum lifts and the volume elements can also be incorporated in this picture. In particular, we pass from \(D_t\) to \(D'_t\) by canonical isomorphisms between volume elements of \(\tilde{\Gamma}, \tilde{\Gamma}_t\) and \(\tilde{\Gamma}^E\).

As we will see in a next paper, the quantum propagator viewed as a function of time is actually a Lagrangian state associated with \(\tilde{\Gamma}\). This statement is delicate because here we mix real and complex variables, cotangent bundles and Kähler manifolds, and the description of Lagrangian states is rather different in these two settings. To give a sense to this, we will perform a Bargmann transform so that the quantum propagator will become a holomorphic function of the complex variable \(t + iE\). This point of view will be interesting, even for the proof of Theorem 1.1, to understand the transport equation satisfied by the leading order term of the amplitude.

1.4 Comparison with earlier results

The introduction of Fourier integral operators with application to the Schrödinger equation and spectral properties of pseudodifferential operators has its origin in the seminal Hörmander [14] and Duistermaat-Guillemin [11] papers, cf. the survey [12]. In these first developments, the operator under study is the Laplace-Beltrami operator and the corresponding classical flow is the geodesic flow.

The transcription of these results to Berezin-Toeplitz operators has been done in the paper [2] by Bothwick-Paul-Uribe, by applying the Boutet de Monvel-Guillemin approach of [3]. Similar results have been proved in a
recent paper [20] by Zelditch-Zhou where the application to spectral densities has been pushed further. These papers both rely on the Boutet de Monvel-Guillemin book [3]. In particular the properties of Berezin-Toeplitz operators are deduced from the pseudodifferential calculus, and the quantum propagator is viewed as a Fourier integral operator. From this is deduced the asymptotics of the smoothed spectral projector on the diagonal, [2, Theorem 1.1] and [20, Theorem 2.2]. The leading order term is computed in terms of the symbolic calculus of Fourier integral operator of Hermite type in [2], or with a non-linear problem in Bargmann space in [20]. It would be interesting to compare these results to ours; unfortunately, we have not been able to do so. Another description of the kernel of the quantum propagator associated with an autonomous Hamiltonian was obtained by Ioos [16], but again, we could not compare our results precisely. This description involves quantities related with parallel transport in the canonical bundle with respect to a connection induced by the transport of the initial complex structure by the Hamiltonian flow, and computing these coefficients appears to be quite complicated in general, relatively to our formulas.

The techniques that we use come from the work of the first author where a direct definition of Lagrangian states on a Kähler manifold is used [6] and the half-form bundles are developed for Berezin-Toeplitz operators [7]. The isomorphisms (5) have been introduced in [8], [9] where their square roots are called half-form bundle morphisms. A similar invariant appears in [20] under the form (6). The main novelty in our results is the precise computation of the coefficients $\rho_t(x)$ and $\rho'_t(x)$ appearing in Theorems 1.1, 1.2.

Whereas the relation between the quantum propagator and the Hamiltonian flow is a classical result, the similar statement for the smoothed spectral projector and the Lagrangian immersion (9) seems to be new. In [2] and [20], only the diagonal behavior of the Schwartz kernel is described. To state our result, we will introduce a general class of Lagrangian states associated with Lagrangian immersions.

1.5 Outline of the paper

Section 2 is devoted to time-dependent Lagrangian states, that we call Lagrangian state families. The main result is that these states provide solutions to the Schrödinger equation with quantum Hamiltonian a Toeplitz operator and initial data a Lagrangian state, cf. Theorem 2.4. The principal symbol of these solutions satisfies a transport equation, that is solved in Section 2.3, while in Section 3, we give an elegant expression in the context of metaplectic quantization. These results will be applied in Section 4 to the quantum
propagator, where Theorem 1.1 is proved.

In Section 5, we prove that the Fourier transform of a time-dependent Lagrangian state is a Lagrangian state as well, with an underlying Lagrangian manifold which is in general only immersed and not embedded, cf. Theorem 5.4. The needed adaptations in the Lagrangian state definition for immersed manifolds are given in Section 5.2. In Section 6, we deduce Theorem 1.2 on the smoothed spectral projector.

2 Propagation of Lagrangian states

2.1 Families of Lagrangian states

To define a Lagrangian state, we need a Lagrangian submanifold of $M$ equipped with a flat unitary section of the prequantum bundle $L$. Let us consider a one-parameter family of such pairs. More precisely, let $I \subset \mathbb{R}$ be an open interval, $C_{I}$ be the trivial complex line bundle over $I$, $\Gamma$ be a closed submanifold of $I \times M$ and $s \in C^\infty(\Gamma, C_{I} \boxtimes L)$ be such that

1. the map $q : \Gamma \to I$, $q(t, x) = t$ is a proper submersion. So for any $t \in I$, the fiber $\Gamma_t := \Gamma \cap (\{t\} \times M)$ is a submanifold of $M$,

2. for any $t \in I$, $\Gamma_t$ is a Lagrangian submanifold of $M$ and the restriction of $s$ to $\Gamma_t$ is flat and unitary.

**Remark 2.1.**

a. Since $q$ is a proper submersion, by Ehresmann’s lemma, $\Gamma$ is diffeomorphic to $I \times N$ for some manifold $N$ in such a way that $q$ becomes the projection onto $I$.

b. Given a proper submersion $q : \Gamma \to I$ and a map $f : \Gamma \to M$, it is equivalent that the map $\Gamma \to I \times M$, $x \to (q(x), f(x))$ is a proper embedding and that for any $t$, $f(t, \cdot) : \Gamma_t \to M$ is an embedding. We decided to start from a closed submanifold of $I \times M$ to be more efficient in the definition of Lagrangian states below.

We will consider states $\Psi_k$ in $\mathcal{H}_k$ depending smoothly on $t \in I$, so $\Psi_k$ belongs to $C^\infty(I, \mathcal{H}_k)$. Equivalently $\Psi_k$ is a smooth section of $C_{I} \boxtimes (L^k \otimes L')$ such that $\overline{\partial} \Psi_k = 0$. Here the $\overline{\partial}$ operator only acts on the $M$ factor. Similarly, it makes sense to differentiate with respect to $t \in I$ a section of $C_{I} \boxtimes A$, where $A$ is any vector bundle over $M$. 

11
A Lagrangian state family associated with \((\Gamma, s)\) is a family \((\Psi_k \in C^\infty(I, H_k), k \in \mathbb{N})\) such that for any \(N\),

\[
\Psi_k(t, x) = \left(\frac{k}{2\pi}\right)^\frac{d}{2} F^k(t, x) \sum_{\ell=0}^{N} k^{-\ell} a_\ell(t, x) + R_N(t, x, k) \tag{12}
\]

where

- \(F\) is a section of \(C_I \otimes L\) such that \(F|_\Gamma = s\), \(\overline{\partial} F\) vanishes to infinite order along \(\Gamma\) and \(|F| < 1\) outside of \(\Gamma\),

- \((a_\ell)\) is a sequence of sections of \(C_I \otimes L'\) such that \(\overline{\partial} a_\ell\) vanishes to infinite order along \(\Gamma\),

- for any \(p\) and \(N\), \(\partial^p R_N = \mathcal{O}(k^{p-N-1})\) in pointwise norm uniformly on any compact subset of \(I \times M\).

It is not difficult to adapt the arguing of [6, Section 2] and to prove the following facts. First, the section \(F\) exists. Second, we can specify arbitrarily the coefficients \(a_\ell\) of the asymptotic expansion along \(\Gamma\) and this determines \((\Psi_k)\) up to \(\mathcal{O}(k^{-\infty})\). More precisely, for any sequence \((b_\ell) \in C^\infty(\Gamma, C_I \otimes L')\), there exists a Lagrangian state \((\Psi_k)\) satisfying for any \(y \in \Gamma\)

\[
\Psi_k(y) = \left(\frac{k}{2\pi}\right)^\frac{d}{2} s^k(y) \sum_{\ell=0}^{N} k^{-\ell} b_\ell(y) + \mathcal{O}(k^{-N-1}) \quad \forall N.
\]

Furthermore, \((\Psi_k)\) is unique up to a family \((\Phi_k \in C^\infty(I, H_k), k \in \mathbb{N})\) satisfying \(||(\frac{d}{dt})^p \Phi_k(t)|| = \mathcal{O}(k^{-N})\) for any \(p\) and \(N\) uniformly on any compact subset of \(I\).

We will call the formal series \(\sum \hbar^\ell b_\ell\) the full symbol of \((\Psi_k)\). The first coefficient \(b_0\) will be called the principal symbol.

It could be interesting to define Lagrangian state families with a different regularity with respect to \(t\). Here, our ultimate goal is to solve a Cauchy problem, so we will differentiate with respect to \(t\) and in a later proof, we will use that \((k^{-1} \partial_t \Psi_k)\) is still a Lagrangian state family. So we need to consider states which are smooth in \(t\). Observe that in the estimate satisfied by \(R_N\) we lose one power of \(k\) for each derivative; this is consistent with the fact that \(\partial_t (F^k) = kF^k f\) where \(f\) is the logarithmic derivative of \(F\), that is \(\partial_t F = f F\).

A last result which is an easy adaptation of [6, section 2.4] is the action of Toeplitz operators on Lagrangian state families. Let \((T_{k,t})\) be a time-dependent Toeplitz operator and \((\Psi_{k,t})\) be a Lagrangian state as above.
Then \((T_{k,t}\Psi_{k,t})\) is a Lagrangian state family associated with \((\Gamma, s)\) as well. Furthermore, its full symbol is equal to \(\sum h^{s+m}Q_m(b_\ell)\) where \(\sum h^{s}b_\ell\) is the full symbol of \((\Psi_k)\) and the \(Q_m\) are differential operators acting on \(C^\infty(\Gamma, C_I \otimes L')\) and depending only on \((T_{k,t})\). In particular, \(Q_0\) is the multiplication by the restriction to \(\Gamma\) of the principal symbol of \((T_k)\).

### 2.2 Propagation

Consider the same data \(\Gamma \subset I \times M\) and \(s \in C^\infty(\Gamma, C_I \otimes L)\) as in the previous section. We claim that the covariant derivative of \(s\) has the form

\[
\nabla s = i\tau dt \otimes s \quad \text{with} \quad \tau \in C^\infty(\Gamma, \mathbb{R}). \tag{13}
\]

Here the covariant derivative is induced by the trivial derivative of \(C_I\) and the connection of \(L\). To prove (13), use that the restriction of \(s\) to each \(\Gamma_t\) is flat. So \(\nabla s = i\alpha \otimes s\), with \(\alpha \in \Omega^1(\Gamma, \mathbb{R})\) vanishing in the vertical directions of \(q: \Gamma \to I\). So \(\alpha = \tau dt\) for some function \(\tau \in C^\infty(\Gamma, \mathbb{R})\).

In the following two propositions, \((\Psi_k)\) is a Lagrangian state family associated with \((\Gamma, s)\) with full symbol \(b(h) = \sum h^{s}b_\ell\).

**Proposition 2.2.** \(((ik)^{-1}\partial_t \Psi_k)\) is a Lagrangian state family associated with \((\Gamma, s)\) with full symbol \((\tau + hP)b(h)\), where \(P\) is a differential operator of \(C^\infty(\Gamma, C_I \otimes L')\).

**Proof.** Differentiating the formula (12) with respect to \(t\), we obtain on a neighborhood of \(\Gamma\) that

\[
\partial_t \Psi_k = \left(\frac{k}{2\pi}\right)^\frac{n}{2} F^k \sum_\ell k^{-\ell}(kfa_\ell + \partial_t a_\ell)
\]

where \(f \in C^\infty(I \times M)\) is the logarithmic derivative of \(F\) with respect to time, so \(\partial_t F = fF\). Using that \(\partial\) and the derivative with respect to \(t\) commute, we easily prove that \(\partial f\) and \(\partial(\partial_t a_\ell)\) both vanish to infinite order along \(\Gamma\). This shows that \((k^{-1}\partial_t \Psi_k)\) is a Lagrangian state associated with \((\Gamma, s)\).

Its full symbol is the restriction to \(\Gamma\) of the series \(\sum h^{\ell}(fa_\ell + h\partial_t a_\ell)\). We claim that \(f|_\Gamma = i\tau\). Indeed, at any point of \(\Gamma\), \(\nabla F\) vanishes in the directions tangent to \(M\), because it vanishes in the directions of type \((0, 1)\) and in the directions tangent to \(\Gamma_t\) as well. So \(\nabla F = fdt \otimes F\) along \(\Gamma\). The restriction of \(F\) to \(\Gamma\) being \(s\), (13) implies that \(f|_\Gamma = i\tau\).

Using similarly that at any \(x \in \Gamma_t\), \((T_x\Gamma_t \otimes C) \oplus T^{0,1}_x M = T_x M \otimes C\), and \(\partial a_\ell = 0\) along \(\Gamma\), it comes that \(\partial_t a_\ell = \nabla_Z a_\ell\) along \(\Gamma\), where \(Z(t, x) \in T_{(t,x)} \Gamma\) is the projection of \(\partial/\partial t\) onto \(T_{(t,x)} \Gamma\) parallel to \(T^{0,1}_x M\). This concludes the proof with \(P\) the operator \(\frac{1}{i}\nabla_Z\). \(\square\)
We now assume that $(\Gamma, s)$ is obtained by propagating a Lagrangian submanifold $\Gamma_0$ of $M$ and a flat section $s_0$ of $L \to \Gamma_0$ by a Hamiltonian flow and its prequantum lift. Let $(H_t)$ be the time-dependent Hamiltonian generating our flow $(\phi_t)$ and denote by $\phi_t^L$ its prequantum lift defined as in the introduction by (3). So we set

$$\Gamma_t = \phi_t(\Gamma_0), \quad s_t(\phi_t(x)) = \phi_t^L(x)s_0(x).$$

Let $Y$ be the vector field of $\mathbb{R} \times M$ given by $Y(t, x) = \frac{\partial}{\partial t} + X_t(x)$ where $X_t$ is the Hamiltonian vector field of $H_t$.

Introduce a time-dependent Toeplitz operator $(T_{k,t})$ with principal symbol $(H_t)$.

**Proposition 2.3.** $(\frac{1}{i k} \partial_t \Psi_k + T_{k,t} \Psi_k)$ is a Lagrangian state family associated with $(\Gamma, s)$ with full symbol $\hbar (\frac{1}{i} \nabla_Y + \zeta)b_0 + \mathcal{O}(\hbar^2)$ for some $\zeta \in \mathcal{C}^\infty(\Gamma)$.

**Proof.** By Proposition 2.2 and the last paragraph of section 2.1, we already know that $(\frac{1}{i k} \partial_t \Psi_k + T_{k,t} \Psi_k)$ is a Lagrangian state with full symbol

$$(\tau(t, x) + H_t(x))(b_0 + \hbar b_1) + hQb_0 + \mathcal{O}(h^2), \quad (14)$$

where $Q$ is a differential operator acting on $\mathcal{C}^\infty(\Gamma, \mathcal{C} \otimes L')$. By differentiating (3) in the definition of $s_t$ and by the fact that $\nabla s = i\tau dt \otimes s$, it comes that

$$\tau(t, \phi_t(x)) + H_t(\phi_t(x)) = 0, \quad (15)$$

so the leading order term in (14) is zero. Consider $f \in \mathcal{C}^\infty(\mathbb{R} \times M)$ and compute the commutator

$$[\frac{1}{i k} \partial_t + T_{k,t}, T_k(f)] = \frac{1}{i k} (T_k(\partial_t f) + T_k(\{H_t, f\}) + \mathcal{O}(k^{-2})$$

$$= \frac{1}{i k} T_k(Yf) + \mathcal{O}(k^{-2}).$$

Letting this act on our Lagrangian state family $\Psi_k$, it comes that $[Q, f]|_\Gamma = \frac{1}{i}(Yf)|_\Gamma$. Since this holds for any $f$, this proves that $iQ$ is a derivation in the direction of $Y$ so $iQ = \nabla_Y + i\zeta$ for some function $\zeta$.

**Theorem 2.4.** For any Lagrangian state $(\Psi_{0,k} \in \mathcal{H}_k)$ associated with $(\Gamma_0, s_0)$, the solution of the Schrödinger equation

$$\frac{1}{i k} \partial_t \Psi_k + T_{k,t} \Psi_k = 0, \quad \Psi_k(0, \cdot) = \Psi_{0,k} \quad (16)$$

is a Lagrangian state family associated with $(\Gamma, s)$ with symbol $b_0 + \mathcal{O}(\hbar)$ where $b_0$ satisfies the transport equation $\frac{1}{i} \nabla_Y b_0 + \zeta b_0 = 0$. 14
Since the integral curves of $Y$ are $t \mapsto (t, \phi_t(x))$, the solution of the transport equation is

$$b_0(t, \phi_t(x)) = e^{\int_0^t \zeta(r, \phi_r(x)) dr} T^L_t(x) b_0(0, x).$$

(17)

In the next section, we will give a geometric formula for $\zeta$ in terms of the canonical bundle.

Proof. The proof is the same as for differential operators (see the proof of Theorem 20.1 in [19] for instance), so we only sketch it. We successively construct the coefficients $b_t$ to solve

$$\frac{1}{h} \partial_t \Psi_k + T_k, t \Psi_k = O(k^{-N})$$

with initial condition $\Psi_k(0, \cdot) = \Psi_{0,k} + O(k^{-N})$. At each step, we have to solve a transport equation $\nabla_Y b_N + db_N = \tau_N$ with initial condition $b_N(0, \cdot) = b_{0,N}$, which has a unique solution. This provides us with a Lagrangian state $(\Psi_k)$ such that both equations of (16) are satisfied up to a $O(k^{-\infty})$. Then, applying Duhamel’s principle, we show that the difference between $\partial_t \Psi_k$ and the actual solution of (16) is a $O(k^{-\infty})$ uniformly on any bounded interval.

2.3 Transport equation

We will now give a formula for the function $\zeta$ and solve the above transport equation. Essential to our presentation are line bundle isomorphisms involving the canonical bundle $K$ of $M$ and the determinant bundles $\Lambda^n T^* \Gamma_t$ and $\Lambda^{n+1} T^* \Gamma$.

First, for any $t \in I$, let $K_t$ be the restriction of $K$ to $\Gamma_t$. Then we have an isomorphism

$$K_t \simeq \det(T^* \Gamma_t) \otimes \mathbb{C}$$

(18)

defined by sending $\Omega \in (K_t)_x = \Lambda^{n,0} T^*_x M$ to its restriction to $T_x \Gamma_t \subset T_x M$. This is an isomorphism because $(T^*_t \Gamma_t \otimes \mathbb{C}) \cap T_x^{0,1} M = \{0\}$, which follows from the fact that $\Gamma_t$ is Lagrangian.

Second, $\Gamma_t$ being a fiber of $\Gamma \to I$, the linear tangent maps to the injection $\Gamma_t \to \Gamma$ and the projection $\Gamma \to \mathbb{R}$ give an exact sequence

$$0 \to T_x \Gamma_t \to T_{(t,x)} \Gamma \to \mathbb{R} = T^*_t I \to 0.$$

Since $\mathbb{R}$ has a canonical volume element, we obtain an isomorphism

$$\det(T^* \Gamma_t) \simeq \det(T^* \Gamma)|_{\Gamma_t}$$

(19)
defined in the usual way: for any \( \alpha \in \bigwedge^n T^*_{(t,x)} \Gamma \), one sends \( dt \wedge \alpha \in \bigwedge^{n+1} T^*_{(t,x)} \Gamma \) into the restriction of \( \alpha \) to \( T_x \Gamma_t \).

Gathering these two isomorphisms, we get a third one:

\[
K|_\Gamma := (\mathbb{C} I \boxtimes K)|_\Gamma \stackrel{\sim}{\rightarrow} \det(T^* \Gamma) \otimes \mathbb{C}, \quad (1 \boxtimes \alpha)|_\Gamma \mapsto j^*(dt \wedge \alpha) \tag{20}
\]

for any \( \alpha \in \Omega^{n,0}(M) \) with \( j \) the embedding \( \Gamma \to I \times M \). On the one hand, \( K|_\Gamma \) has a natural connection induced by the Chern connection of \( K \), which gives us a derivation \( \nabla_Y \) acting on sections of \( K|_\Gamma \). On the other hand, the Lie derivative \( \mathcal{L}_Y \) acts on the differential forms of \( \Gamma \), and in particular on the sections of \( \det(T^* \Gamma) \). Under the isomorphism (20),

\[
\mathcal{L}_Y = \nabla_Y + i\theta
\]

where \( \theta \in C^\infty(\Gamma) \) since \( \mathcal{L}_Y \) and \( \nabla_Y \) are derivatives in the same direction \( Y \).

**Theorem 2.5.** The function \( \zeta \) defined in Proposition 2.3 satisfies the equality \( \zeta = \frac{1}{2} \theta + H_{sub}|_\Gamma \).

The proof is postponed to Section 7 since it does not help to understand what follows and it is quite technical. On the one hand, we can compute \( \theta \) in terms of second derivatives of \( H_t \), cf. Proposition 7.1. On the other hand, we directly compute the function \( \zeta \), cf. Proposition 7.2.

We will now give an explicit expression for the term involving \( \zeta \) in the solution (17) of the transport equation in light of Theorem 2.5. For any \( t \in I \), the tangent map to \( \phi_t \) restricts to an isomorphism from \( TT_0 \) to \( TT_t \). By the identification (18), we get an isomorphism \( \mathcal{E}_t \) from \( K|_{\Gamma_0} \) to \( K|_{\Gamma_t} \) lifting \( \phi_t \). More precisely, for any \( x \in \Gamma_0, u \in K_x \) and \( v \in \det(T_x \Gamma_0) \), we define \( \mathcal{E}_t(x)u \in K_{\phi_t(x)} \) so that

\[
(\mathcal{E}_t(x)u)((T_x \phi_t)_x, v) = u(v). \tag{21}
\]

The parallel transport \( \mathcal{T}^{K}_t \) restricts as well to an isomorphism \( K|_{\Gamma_0} \to K|_{\Gamma_t} \). Define the complex number \( C_t(x) \) by \( \mathcal{E}_t(x) = C_t(x) \mathcal{T}^{K}_t(x) \).

**Proposition 2.6.** The solution of the transport equation \( \frac{1}{i} \nabla_Y b + \zeta b = 0 \) with \( b \in C^\infty(\Gamma, L') \) is

\[
b(t, \phi_t(x)) = C_t(x)^\frac{1}{2} e^{\frac{1}{i} \int_0^t H_{sub}(\phi_r(x)) \, dr} \mathcal{T}^{L'}_t(x) b(0, x) \tag{22}
\]

with the square root of \( C_t(x) \) chosen continuously and \( C_0 = 1 \).
Proof. In view of Equation (17) and Theorem 2.5, it suffices to deal with
the case $H^{\text{sub}}_{|\Gamma} = 0$. Moreover, observe that if $\tilde{b}$ satisfies $\nabla_Y \tilde{b} = 0$ if and only if $\frac{1}{i} Y.f + \zeta f = 0$. So it suffices to
prove that $f : (t, \phi_t(x)) \mapsto C_t(x)^{1/2}$ is a solution of the latter equation.

First the isomorphism $I \times \Gamma_0 \simeq \Gamma$, $(t, x) \mapsto (t, \phi_t(x))$ sends the vector
field $\partial_t$ to $Y$. The solutions of $L_{\partial_t} \beta = 0$ with $\beta \in \Omega^{n+1}(I \times \Gamma_0)$ have the
form $\beta = dt \wedge \beta_0$ with $\beta_0 \in \Omega^n(\Gamma_0)$. So the solutions of $L_Y \alpha = 0$ with $\alpha \in \Omega^{n+1}(\Gamma)$ are parametrised by $\alpha_0 \in \Omega^n(\Gamma_0)$ and given by

$$\alpha|(t,\phi_t(x)) = dt \wedge (\phi_t^*)^{-1} \alpha_0|_x.$$  

Now, identify $K_\Gamma$ and $\det(T^*\Gamma) \otimes \mathbb{C}$ through (20). Then by (21), the previous
equation becomes

$$\alpha|(t,\phi_t(x)) = E_t(x) \alpha|(0,x).$$

Second, the solutions of $\nabla_Y \alpha' = 0$ with now $\alpha' \in C^\infty(\Gamma, K_\Gamma)$ are given by

$$\alpha'|_{(t,\phi_t(x))} = T_t^K(x) \alpha'|_{(0,x)}.$$  

Assume that $\alpha'|_{(0,x)} = \alpha|_{(0,x)}$: then we have $\alpha = C \alpha'$ with $C \in C^\infty(\Gamma)$
defined by $C(t, \phi_t(x)) = C_t(x)$. Therefore

$$0 = L_Y \alpha = L_Y(C \alpha') = (Y.C) \alpha' + C L_Y \alpha' = (Y.C) \alpha' + C \nabla_Y \alpha' + 2i \zeta C \alpha'$$

so $Y.C + 2i \zeta C = 0$, hence $\frac{1}{4} Y.C^{1/2} + \zeta C^{1/2} = 0$. \hfill $\square$

3 Metaplectic correction

It is useful to reformulate the previous results with a half-form bundle.

3.1 Definitions

Recall first some definitions. A square root $(B, \varphi)$ of a complex line bundle $A \to N$ is a complex line bundle $B \to N$ with an isomorphism $\varphi : B \otimes^2 \to A$. A half-form bundle of a complex manifold is a square root of its canonical
bundle. Since the group of isomorphism classes of complex line bundles of a
manifold $N$ is isomorphic to $H^2(N)$, the isomorphism being the Chern class,
a sufficient condition for a complex manifold to have a half-form bundle is
that its second cohomology group is trivial. This condition will be sufficient
for our purposes. Before we discuss the uniqueness, let us explain how
derivatives and connections can be transferred from a bundle to its square roots.

Assume that \((B, \varphi)\) is a square root of \(A\). Then any derivative \(D_B\) acting on sections of \(B\) induces a derivative \(D_A\) acting on sections of \(A\) such that the Leibniz rule is satisfied

\[
D_A(u \otimes v) = D_B(u) \otimes v + u \otimes D_B(v), \quad \forall u, v \in \mathcal{C}^\infty(B)
\]

The converse is true as well: any derivative \(D_A\) of \(A\) determines a derivative \(D_B\) of \(B\) such that the above identity is satisfied. Similarly a covariant derivative \(\nabla_B\) of \(B\) induces a covariant derivative \(\nabla_A\) of \(A\) such that

\[
\nabla_A(u \otimes v) = \nabla_B(u) \otimes v + u \otimes \nabla_B(v), \quad \forall u, v \in \mathcal{C}^\infty(B)
\]

Two square roots \((B, \varphi)\) and \((B', \varphi')\) of \(A\) are isomorphic if there exists a line bundle isomorphism \(\psi : B \to B'\) such that \(\varphi' \circ \psi^2 = \varphi\). The isomorphism classes of square root of the trivial line bundle \(\mathbb{C}_N\) of \(N\) are in bijection with \(H^1(N, \mathbb{Z}_2)\). Indeed, each square root of \(\mathbb{C}_N\) has a natural flat structure with holonomy in \(\{-1, 1\} \subset \mathbb{U}(1)\), induced by the flat structure of \(\mathbb{C}_N\). We easily check this determines the square root up to isomorphism. Furthermore, the tensor product of line bundles defines an action of square roots of \(\mathbb{C}_N\) on the space of square roots of a given line bundle \(A\). This makes the set of isomorphism classes of square root of \(A\) a homogeneous space for the group \(H^1(N, \mathbb{Z}_2)\).

### 3.2 Propagation in terms of half-form bundle

When \(M\) has a half-form bundle \(\delta\), we can reformulate the previous results by introducing a new line bundle \(L_1\) such that \(L' = L_1 \otimes \delta\). The relevant structures of \(L_1\) and \(\delta\) have a different nature:

- \(L_1\) has a natural connection, its Chern connection,
- the restriction of \(\delta\) to a Lagrangian submanifold \(N\) of \(M\) is a square root of \(\det(T^*N) \otimes \mathbb{C}\), through the isomorphism \(K|_N \simeq \det(T^*N) \otimes \mathbb{C}\).

For instance, in our propagation results, on the one hand, the tangent map to the flow defines a map from \(\det(T^0\Gamma_0)\) to \(\det(T^1\Gamma_t)\), which gives the map \(E_t : K|_{\Gamma_0} \to K|_{\Gamma_t}\). We then introduce the square root of \(E_t\)

\[
[E_t(x)]^{\frac{1}{2}} : \delta_x \to \delta_{\varphi_t(x)}, \quad x \in \Gamma_0
\]

which is equal to the identity at \(t = 0\). On the other hand, we can define the parallel transport \(T^{L_1}_t\) from the connection of \(L_1\). Then (22) writes
equivalently
\[ b(t, \phi_t(x)) = e^\frac{i}{2} \int_0^t H_{ab}(r, \phi_r(x)) \, dr \, T^{L_1}(x) \otimes [\mathcal{E}_t(x)]^\frac{1}{2} \, b(0, x) \] (23)

The transport equation \((\nabla + i\zeta)b = 0\) has a similar formulation in terms of the decomposition \(L' = L_1 \otimes \delta\). Here it is convenient to lift everything to \(\Gamma\). So we consider \(C_I \boxtimes L' \to \Gamma\) as the tensor product of \(C_I \boxtimes L_1 \to \Gamma\) and \(\delta_{\Gamma} := (C_I \boxtimes \delta \to \Gamma)\). Then the transport equation is
\[ ((\nabla^{L_1} \otimes \text{id} + \text{id} \otimes \nabla^\delta_Y) + iH_{ab})b = 0 \] (24)

On the one hand, \(\nabla^{L_1}\) is the Chern connection of \(L_1\) with derivative \(\nabla^{L_1}_Y\) acting on \(C^\infty(\Gamma, C_I \boxtimes L_1)\). On the other hand, \(\mathcal{L}^\delta_Y\) is the derivative of \(C^\infty(\Gamma, \delta_{\Gamma})\) induced by the Lie derivative \(L_Y\) of \(\Gamma\) through the isomorphism
\[ \delta_{\Gamma}^2 \simeq K_{\Gamma} \simeq \det(T^*\Gamma) \otimes \mathbb{C} \]

defined by (20). More precisely, \(\mathcal{L}^\delta_Y\) is the unique derivative such that \(\mathcal{L}_Y(s^2) = 2s \otimes \mathcal{L}^\delta_Y s\) for any section \(s \in C^\infty(\Gamma, \delta_{\Gamma})\). Then Formula (24) follows from the relation between \(\zeta\) and \(\theta\) and the fact that \(\nabla^{L_1}_Yb = (\nabla^{L_1}_Y \otimes \text{id} + \text{id} \otimes \nabla^\delta_Y)b\) where \(\nabla^\delta_Y\) is the connection on \(\delta\) induced by the one on \(K\), which satisfies \(\nabla^\delta_Y = \mathcal{L}^\delta_Y - \frac{1}{2} \theta\).

Interestingly, these formulations can be used even when \(M\) has no half-form bundle. To give a meaning to Equation (23), we need a square root \(\delta\) of the restriction of \(K\) to the trajectory \(\phi_{[0, t]}(x)\) of \(x\) on the interval \([0, t]\). This trajectory being an arc or a circle, such a square root exists. In the circle case, there are two square roots up to isomorphism, but it is easy to see that the right-hand side of (23) does not depend on the choice. Similarly we can give a meaning to the transport equation (24) even when \(M\) has no half-form bundle. Indeed a differential operator of \(\Gamma\) is determined by its restriction to the open sets of any covering of \(\Gamma\). And we can always introduce a half-form bundle on the neighborhood of each point of \(M\).

### 3.3 Norm estimates

The introduction of half-form bundles is also useful when we estimate the norm of a Lagrangian state. For instance, consider a Lagrangian state \(\Psi_k(t)\) as in (12). Then, by [7, Theorem 3.2],
\[ \|\Psi_k(t)\|^2_{\mathcal{H}_k} = \int_{\Gamma_t} \Omega_t + \mathcal{O}(k^{-1}) \] (25)
where $\Omega_t$ is a density on $\Gamma_t$, which is given in terms of the principal symbol $b_0(\cdot, t)$ of $\Psi_k(t)$ as follows. We assume that $L' = L_1 \otimes \delta$ with $\delta$ a half-form bundle. Again we treat $\delta$ and $L_1$ in completely different ways. On the one hand, $L_1$ has a natural metric so $L_1 \otimes \overline{L}_1 \simeq \mathbb{C}$. On the other hand, $\delta|_{\Gamma_t}$ being a square root of $\det(T^*\Gamma_t) \otimes \mathbb{C}$, the identity $z \overline{z} = |z|^2$ induces an isomorphism between $\delta|_{\Gamma_t} \otimes \overline{\delta}|_{\Gamma_t}$ and the bundle $|\Lambda|T^*\Gamma_t \otimes \mathbb{C}$ of densities. So we have an isomorphism

$$L'|_{\Gamma_t} \otimes \overline{T_{\Gamma_t}} \simeq |\Lambda|T^*\Gamma_t \otimes \mathbb{C}. \quad (26)$$

Then $\Omega_t$ is the image of $b_0(\cdot, t) \otimes \overline{b}_0(\cdot, t)$ by (26). When $M$ does not have a half-form bundle, we can still define the isomorphism (26) by working locally and the global estimate (25) still holds. The normalization $(k/2\pi)^{n/2}$ in the definition (12) has been chosen to obtain this formula.

Interestingly the isomorphism (20) is also meaningful for our norm estimates. Indeed, consider now $b_0$ as a section of $C_I \otimes L' \to \Gamma$; repeating the previous considerations to $(C_I \otimes \delta)|_{\Gamma_t}$ and $(C_I \otimes L_1)|_{\Gamma_t}$, we define a density $\Omega$ on $\Gamma$ such that

$$\int_I f(t) \, \|\Psi_k(t)\|^2_{\mathcal{H}_k} \, dt = \int_\Gamma (f \circ q) \, \Omega + \mathcal{O}(k^{-1}), \quad \forall f \in C^\infty_0(I). \quad (27)$$

where $q$ is the projection $\Gamma \to I$. This follows from (25), because $\Omega_t$ is the restriction of $\iota_\Omega \Omega$ to $\Gamma_t$ and a geometric version of Fubini’s theorem tells us that $\int_I f(t) \int_{\Gamma_t} \Omega_t = \int_\Gamma (f \circ q) \, \Omega$.

\section{The quantum propagator}

In this section, we prove Theorem 1.1. We will apply the previous considerations to $M \times \overline{M}$, $L \boxtimes \mathcal{L}$ and $L' \boxtimes \overline{\mathcal{L}}'$ instead of $M$, $L$ and $L'$. The holomorphic sections of $(L \boxtimes \mathcal{L})^k \otimes (L' \boxtimes \overline{\mathcal{L}}')$ are the Schwartz kernels of the endomorphisms of $\mathcal{H}_k$.

The symplectic structure of $\overline{M}$ being the opposite of $\omega$, the diagonal $\Delta_M$ is a Lagrangian submanifold of $M \times \overline{M}$. There is a canonical flat section $s : \Delta_M \to L \boxtimes \mathcal{L}$ defined by $s(x, x) = u \otimes \overline{u}$ where $u \in L_x$ is any vector of norm 1. The Lagrangian states corresponding to $(\Delta_M, s)$ are the Toeplitz operators up to a factor $(k/2\pi)^{n/2}$. More precisely, the Schwartz kernel of $(k/2\pi)^{-n/2}T_k(f)$ is a Lagrangian state associated with $(\Delta_M, s)$ with principal symbol $f$, where we identify the restriction of $L' \boxtimes \overline{\mathcal{L}}'$ to the diagonal with the trivial line bundle $\mathbb{C}_M = L' \otimes \overline{\mathcal{L}}'$ by using the Hermitian metric of $L'$. This applies in particular to the identity of $\mathcal{H}_k$, which is the Toeplitz
operator $T_k(1)$ and is actually a reformulation of a theorem by Boutet de Monvel-Sjöstrand \cite{4, 5}.

By Theorem 2.4, the Schwartz kernel of the quantum propagator $(U_{k,t})$ multiplied by $(\frac{k}{2\pi})^{-\frac{n}{2}}$ is a Lagrangian state family, associated with the graph of $\phi_t$ and its prequantum lift. Indeed, in the Schrödinger equation (1), we can interpret the product $T_{k,t}U_{k,t}$ as the action of the Toeplitz operator $T_{k,t} \boxtimes \text{id}$ on $U_{k,t}$. Its principal symbol is $H_t \boxtimes 1$, so its Hamiltonian flow is $\phi_t \boxtimes \text{id}$. There is no difficulty to deduce Formula (8) from Proposition 2.6 except for the relation between $E_t$ and $D_t$.

Lemma 4.1. $E_t(x,x)(\text{id}_{K_x}) = D_t(x)$.

Everything relies on the identification (18) which in our case is an isomorphism between $K_{\phi_t(x)} \otimes K_x$ and the space of volume forms on the graph of $T_x\phi_t$. On the one hand, the elements of $K_{\phi_t(x)} \otimes K_x$ will be viewed as morphisms from $K_x$ to $K_{\phi_t(x)}$. On the other hand, the graph of $T_x\phi_t$ is naturally isomorphic with $T_xM$ through the map $\xi \rightarrow (T_x\phi_t(\xi), \xi)$. So (18) becomes an isomorphism

$$\text{Mor}(K_x, K_{\phi_t(x)}) \simeq \text{det}(T_x^*M) \otimes \mathbb{C}$$

(28)

Now the tangent map to the flow $\phi_t \boxtimes \text{id}$ sends the graph of $T_x\phi_0$ to the graph of $T_x\phi_t$, and with our identifications, it becomes the identity of $T_xM$. So the map $E_t(x,x)$ is the isomorphism

$$\text{Mor}(K_x, K_x) \simeq \text{Mor}(K_x, K_{\phi_t(x)})$$

obtained by applying (28) with $t = 0$ and then the inverse of (28).

Proof of Lemma 4.1, technical part. First we claim that (28) sends a morphism $\psi : K_x \rightarrow K_{\phi_t(x)}$ to

$$((T_x\phi_t)^*\psi(\alpha)) \wedge \overline{\alpha}$$

where $\alpha \in K_x$ is any vector with norm 1. Indeed, $\psi$ is first identified with $\psi(\alpha) \otimes \overline{\alpha} \in K_{\phi_t(x)} \otimes K_x$. Then it is viewed as the $2n$-form of $T_xM \oplus T_xM$ given by $p_1^*\psi(\alpha) \wedge p_2^*\overline{\alpha}$ where $p_1$ and $p_2$ are the projections $T_xM \oplus T_xM \rightarrow T_xM$ onto the first and the second factor respectively. Then it is restricted to the graph of $T_x\phi_t$ which is identified with $T_xM$ via the map $h(\xi) = (T_x\phi_t(\xi), \xi)$, so we obtain

$$h^*(p_1^*\psi(\alpha) \wedge p_2^*\overline{\alpha}) = ((T_x\phi_t)^*\psi(\alpha)) \wedge \overline{\alpha}$$

because $p_1 \circ h = T_x\phi_t$ and $p_2 \circ h = \text{id}$.  

21
For \( t = 0 \) and \( \psi = \text{id} \), we have \( ((T_x \phi_t)^* \psi(\alpha)) \land \overline{\alpha} = \alpha \land \overline{\alpha} \). So we have to prove that for \( \beta = \mathcal{D}_t(x)(\alpha) \)

\[
((T_x \phi_t)^* \beta) \land \overline{\alpha} = \alpha \land \overline{\alpha}
\]  

(29)

This is equivalent to \( j^*(T_x \phi_t)^* \beta = \alpha \) where \( j \) is the injection \( T^1_{x}M \to T_x M \otimes \mathbb{C} \). Since \( \beta \in K_{\phi_t(x)} \), we have \( \pi^* \beta = \beta \) where \( \pi \) is the projection of \( T_{\phi_t(x)} M \otimes \mathbb{C} \) onto the \((1,0)\)-subspace with kernel the \((0,1)\)-subspace. So we have to show that \( (\pi \circ (T_x \phi_t) \circ j)^* \beta = \alpha \). But \( \pi \circ (T_x \phi_t) \circ j = (T_x \phi_t)^{1,0} \), so (29) is equivalent to \( ((T_x \phi_t)^{1,0} \beta = \alpha \). And this last equality is actually the definition of \( \beta = \mathcal{D}_t(x)(\alpha) \).

\[ \tag{29} \]

**Theorem 4.2.** Let \( (T_{k,t}, t \in I) \) be a smooth family of Toeplitz operators with real principal symbol \( H_t \) and subprincipal symbol \( H_t^{\text{sub}} \). Then the Schwartz kernel of the quantum propagator of \( (T_{k,t}) \) multiplied by \( (\frac{1}{2\pi})^{-\frac{3}{2}} \) is a Lagrangian state family associated with \((\Gamma, s, \sigma)\) given by \( \Gamma = \{(t, \phi_t(x), x) / t \in I, x \in M\} \) and

\[
\begin{align*}
\left\{ \begin{array}{l}
\sigma(t, \phi_t(x), x) = \phi_t^L(x) : L_x \to L_{\phi_t(x)}, \\
\sigma(t, \phi_t(x), x) = [\rho_t(x)]^{\frac{1}{2}} e^\frac{1}{2} \int_0^t H_t^{\text{sub}}(\phi_t(x)) \, dr T_t^{L'}(x) : L'_x \to L'_{\phi_t(x)},
\end{array} \right.
\end{align*}
\]

where \( (\phi_t) \) is the Hamiltonian flow of \( H_t \), \( \phi_t^L \) its prequantum lift, \( T_t^{L'} \) its parallel transport lift to \( L' \) and \( \mathcal{D}_t(x) = \rho_t(x) T_t^{L}(x) \) with \( \mathcal{D}_t(x) = K(T_x \phi_t) : K_x \to K_{\phi_t(x)} \).

As explained in the introduction, it is very natural to express the symbol by using a half-form bundle:

\[
\sigma(t, \phi_t(x), x) \equiv e^\frac{1}{2} \int_0^t H_t^{\text{sub}}(\phi_t(x)) \, dr T_t^{L_1}(x) \otimes [\mathcal{D}_t(x)]^{\frac{1}{2}}
\]

where \( L' = L_1 \otimes \delta \) and \( [\mathcal{D}_t(x)]^{\frac{1}{2}} : \delta_x \to \delta_{\phi_t(x)} \) is the continuous square root of \( \mathcal{D}_t(x) \) equal to 1 at \( t = 0 \).

**Remark 4.3.** In our next paper on trace formulas, we will use the following expression for \( \rho_t(x) \). Denote by \( \gamma : \mathbb{R} \to M \), \( t \mapsto \phi_t(x) \) the trajectory of \( x \). Choose a unitary frame \( s_K \) of \( \gamma^* K \) and write \( \nabla s_K = \frac{1}{t} f_K dt \otimes s_K \). Then

\[
\rho_t(x) = c_t e^{-i \int_0^t f_K(r) \, dr} \quad \text{where} \quad c_t \Omega_t(\xi_t u) = \Omega_0(\xi_0 u).
\]

(30)

Here \( u \) is any generator of \( \wedge^\text{top} T_x M \), \( \xi_t \) is the linear map \( T_x M \to T_{\gamma(t)} M \oplus T_x M \) sending \( X \) into \( (T_x \phi_t(X), X) \), and \( \Omega_t \) is the 2n-form of \( T_{\gamma(t)} M \oplus T_x M \).
equal to \( \Omega_t = p_1^*s_K(t) \wedge p_2^*s_K(0) \), \( p_1 \) and \( p_2 \) being the projection on \( T_{\gamma(t)}M \) and \( T_xM \) respectively.

The proof of (30) is that on the one hand \( \mathcal{E}_t(x,x)\Omega_0 = c_t \Omega_t \) and on the other hand \( T_tK(x,x)\Omega_0 = e^{i \int_0^t f_K(r)dr} \Omega_t. \)

\[5\] Fourier Transform of Lagrangian state families

5.1 Symplectic preliminaries

Consider the same data \( \Gamma \subset I \times M \) and \( s \in C^\infty(\Gamma, \mathbb{C}_I \boxtimes L) \) as in Section 2.1. So we assume that \( \Gamma \twoheadrightarrow I, (t,x) \mapsto t \) is a proper submersion and that for any \( t \in I, \Gamma_t \) is a Lagrangian submanifold of \( M \) and the restriction of \( s \) to \( \Gamma_t \) is flat and unitary. Recall that \( \nabla s = i\tau dt \otimes s \) for a function \( \tau \in C^\infty(\Gamma) \), cf (13). For any \( E \) in \( \mathbb{R} \), introduce

\[\Gamma^E := \{(t,x) \in \Gamma \mid \tau(t,x) + E = 0\}.\] (31)

**Proposition 5.1.** Let \( E \) be a regular value of \(-\tau\). Then

1. \( \Gamma^E \) is a submanifold of \( \Gamma \) and \( j_E : \Gamma^E \rightarrow M, (t,x) \mapsto x \) is a Lagrangian immersion,

2. \( j : \Gamma \rightarrow \mathbb{R} \times M, (t,x) \mapsto (\tau(t,x),x) \) is an immersion at any \((t_0,x_0) \in \Gamma^E,\)

3. the section \( s^E \) of \((j^E)^*L \) given by \( s^E(t,x) = e^{itE}s(t,x) \) is flat.

**Proof.** For any tangent vectors \( Y_1 = (a_1,\xi_1), Y_2 = (a_2,\xi_2) \) in \( T_{(t_0,x_0)}\Gamma \subset \mathbb{R} \oplus T_{x_0}M \), we have

\[\omega(\xi_1,\xi_2) = a_1 d\tau(Y_2) - a_2 d\tau(Y_1)\] (32)

To prove this, we extend \( Y_1 \) and \( Y_2 \) to vector fields of \( \Gamma \) on a neighborhood of \((t_0,x_0)\) so that \([Y_1,Y_2] = 0\). Then, the curvature of \( \nabla \) being \( \frac{1}{i}\omega \), we have that

\[[\nabla Y_1, \nabla Y_2] = \frac{1}{i} \omega(\xi_1,\xi_2).\]

Furthermore, since \( dt(Y_j) = a_j \), we have that \( \nabla Y_j s = ia_j \tau \otimes s \) so \( \nabla Y_1 \nabla Y_2 s = i((Y_1.a_2)\tau + a_2(Y_1,\tau))s - a_1 a_2 \tau^2 s \). Using that \( Y_1.a_2 - Y_2.a_1 = [Y_1,Y_2].t = 0 \), it comes that

\[[\nabla Y_1, \nabla Y_2]s = i(a_2(Y_1,\tau) - a_1(Y_2,\tau))s.\]

Comparing with the previous expression for the curvature, we obtain (32).
We prove the second assertion. Assume \( Y_1 = (a_1, \xi_1) \) is in the kernel of the tangent map of \( j : \Gamma \to \mathbb{R} \times M \), that is \( d\tau(Y_1) = 0 \) and \( \xi_1 = 0 \). Then (32) writes \( 0 = a_1 d\tau(Y_2) \). If \( a_1 \neq 0 \), this implies that \( d\tau(Y_2) = 0 \) for any \( Y_2 \in T_{(t_0, x_0)} \Gamma \), which contradicts the assumption that \( -E \) is a regular value of \( \tau \).

This implies that \( j_E \) is an immersion. It is Lagrangian by (32) again because if \( Y_1, Y_2 \) are tangent to \( \Gamma^E \), then \( d\tau(Y_1) = d\tau(Y_2) = 0 \), so \( \omega(\xi_1, \xi_2) = 0 \). Finally, \( \nabla(e^{itE}s) = (iEdt + i\tau dt) \otimes e^{itE}s = 0 \) on \( \Gamma^E \). \qed

5.2 Immersed Lagrangian states

We will adapt the definition of Lagrangian states for immersed manifolds. Suppose we have a Lagrangian immersion \( j : N \to M \), a flat unitary section \( s \) of \( j^*L \) and a formal series \( \sum \ell h^\ell b_\ell \) with coefficients \( b_\ell \in C^\infty(j^*L') \).

First, for any \( y \in N \), we will define a germ of Lagrangian state at \( j(y) \), uniquely defined up to \( \mathcal{O}(k^{-\infty}) \) as follows. Let us assume temporarily that there exists an open set \( V \) in \( M \) such that \( j : N \to V \) is a proper embedding, so that \( j(N) \) is a closed submanifold of \( V \). Then we can introduce sections \( F : V \to L \) and \( a_\ell : V \to L' \) such that \( \overline{\partial} F \) and \( \overline{\partial} a_\ell \) vanish to infinite order along \( j(N) \), \( j^*F = s \) and \( j^*a_\ell = b_\ell \) and \( |F| < 1 \) on \( V \setminus j(N) \). These sections are not unique but if \( (F', a_\ell', \ell \in \mathbb{N}) \) satisfy the same condition, then for any \( N \),

\[
F^k \sum_{\ell=0}^{N} k^{-\ell} a_\ell = (F')^k \sum_{\ell=0}^{N} k^{-\ell} a_\ell' + \mathcal{O}(k^{-N-1}) \tag{33}
\]

the \( \mathcal{O} \) being uniform on any compact set of \( V \). This follows on one hand from the fact that \( |F| \) and \( |F'| \) are \(< 1\) on \( V \setminus j(N) \), so that both sides of (33) are in \( \mathcal{O}(k^{-N-1}) \) uniformly on any compact set of \( V \setminus j(N) \). On the other hand, the sections \( F, F' \) and \( a_\ell, a_\ell' \) have the same Taylor expansions along \( j(N) \) which implies (33) on a neighborhood of \( j(N) \), (see [6, Section 2.2] for details).

Back to a general immersion \( N \to M \), for any \( y \in N \), by the local normal form for immersions, there exists open neighborhoods \( U \) and \( V \) of \( y \) and \( j(y) \) respectively such that \( j(U) \subset V \) and \( j \) restricts to a closed embedding from \( U \) into \( V \). Then we can introduce the sections \( F \) and \( a_\ell, \ell \in \mathbb{N} \) as above on \( V \), which extend the restrictions of \( s \) and \( b_\ell \) to \( U \). This defines the expansion

\[
\Psi_{N,k} := F^k \sum_{\ell=0}^{N} k^{-\ell} a_\ell \tag{34}
\]
on $V$. If we have another set of data $(U', V', F', a'_\ell)$, we obtain another sequence $\Psi'_{N,k} := (F')^k \sum_{\ell=0}^N k^{-\ell} a'_\ell$ on $V'$.

**Lemma 5.2.** For any $N$, $\Psi_{N,k} = \Psi'_{N,k} + \mathcal{O}(k^{-N-1})$ on a neighborhood of $j(y)$.

So we have a well defined germ of Lagrangian states at $j(y)$.

**Proof.** Choose open sets $W$ and $W'$ of $V$ and $V'$ respectively such that $j(U \cap U') = j(U) \cap W = j(U') \cap W'$. Set $U'' = U \cap U'$ and $V'' = W \cap W'$. Then $j$ restricts to an embedding from $U''$ into $V''$ and $j(U'') = j(U') \cap V''$. So the restriction of $F$, $a_\ell$ to $V''$ gives us a new set of data $(U'', V'', F|_{V''}, a_\ell|_{V''})$. The fact that $j(U'') = j(U') \cap V''$ is used to see that $|F| < 1$ on $V'' \setminus j(U'')$. Similarly, we can restricts $F'$, $a'_\ell$ to $V''$ and get $(U'', V'', F'|_{V''}, a'_\ell|_{V''})$. The final result follows from our initial remark (33).

Now assume that there exists a compact subset $K$ of $N$ such that for each $\ell$, $a_\ell$ is supported in $K$. Our goal is to construct a Lagrangian state which, on a neighborhood of each $x \in M$, is equal to the sum of the local Lagrangian states defined previously for each $y \in j^{-1}(x) \cap K$. An essential observation is that $j^{-1}(x)$ is discrete in $N$, so $j^{-1}(x) \cap K$ is finite since $K$ is compact.

**Lemma 5.3.** There exists a family $(\Psi_k \in \mathcal{H}_k)$ such that for any $x \in M$ and any $N$:

1. if $x \notin j(K)$, $|\Psi_k| = \mathcal{O}(k^{-N})$ on a neighborhood of $x$,
2. if $j^{-1}(x) \cap K = \{y_i, i \in I\}$, then $\Psi_k = \sum_i \Psi^i_{N,k} + \mathcal{O}(k^{-N})$ on a neighborhood of $x$, where each $\Psi^i_{N,k}$ is defined as in (34) with $y = y_i$.

We will call $(\Psi_k)$ a Lagrangian state associated with the Lagrangian immersion $j : N \to M$, the flat unitary section $s$ of $j^* L$ and the formal series $\sum h^\ell b_\ell$ with coefficients in $C^\infty(N, j^* L')$. $(\Psi_k)$ is unique up to $\mathcal{O}(k^{-\infty})$. But unlike the case of a Lagrangian submanifold, we can not recover the symbol $\sum h^\ell b_\ell$ from the state by taking the restriction to $j(N)$ because of the possible multiple points.

**Proof.** Consider an open set $V$ of $M$ and a finite family $(U_i)_{i \in I}$ of disjoint open sets of $N$ such that for any $i \in I$, $j$ restricts to a proper embedding
from $U_i$ into $V$ and $K \cap j^{-1}(V) \subset \bigcup U_i$. Then introduce sections $F_i, a_{i,\ell}$ on $V$ as above associated with each submanifold $j(U_i)$. Consider the sum

$$\left(\frac{k}{2\pi}\right)^\frac{n}{2} \sum_{i \in I} F_i^k(x) \sum_{\ell=0}^N k^{-\ell} a_{i,\ell}(x), \quad x \in V. \quad (35)$$

Then for any $x \in V$, each $y \in j^{-1}(x) \cap K$ belongs to one of the $U_i$, so on a neighborhood of $x$, $(35)$ is equal to the sum of the Lagrangian state germs associated with the $y \in j^{-1}(x) \cap K$. So by the previous discussion, the state defined by $(35)$ on a neighborhood of $x$ does not depend, up to $O(k^{-\infty})$, on the choice of $(V, U_i, F_i, a_{i,\ell}, i \in I, \ell \in \mathbb{N})$. It is not difficult to prove that any point $x$ of $M$ has an open neighborhood $V$ admitting a family $(U_i)$ as above. Indeed, if we set $I = j^{-1}(x) \cap K$, then for any $y \in I$, there exists a pair $(U_y \ni y, V_y)$ such that $j$ restricts to a proper embedding from $U_y$ into $V_y$. Then we choose for $V$ a sufficiently small neighborhood of $x$ in $\cap_y V_y$ such that $j^{-1}(V) \cap K \subset \cup_y U_y$ and we restrict the $U_y$ accordingly. So with a partition of unity, we can construct global states $\Psi_k \in C^\infty(M, L^k \otimes L'), k \in \mathbb{N}$, such that for any data $(V, U_i, i \in I)$ as above, $\Psi_k$ is equal to $(35)$ on $V$ up to a $O(k^{-\infty})$, uniform on any compact subset of $V$. Since $\bar{\partial}\Psi_k$ is in $O(k^{-\infty})$, we can replace $\Psi_k$ by its projection onto $\mathcal{H}_k$, which only modifies it by a $O(k^{-\infty})$ by Kodaira-Hörmander estimates [17, 13].

5.3 Fourier transform

Introduce the $h$-Fourier transform and its inverse with parameter $k = h^{-1}$

$$\mathcal{F}_k(f)(t) = \left(\frac{k}{2\pi}\right)^\frac{1}{2} \int_{\mathbb{R}} e^{-iktE} f(E) dE, \quad \mathcal{F}_k^{-1}(g)(E) = \left(\frac{k}{2\pi}\right)^\frac{1}{2} \int_{\mathbb{R}} e^{iktE} g(t) dt. $$

We are now ready to state the main result of this section.

**Theorem 5.4.** Let $(\Psi_k \in C^\infty(I, \mathcal{H}_k), k \in \mathbb{N})$ be a Lagrangian state family associated with $(\Gamma, s)$ and such that the $\Psi_k$ are supported in a compact set of $I$ independent of $k$. Let $-E$ be a regular value of $\tau$ and $\Gamma^E := \tau^{-1}(-E)$.

Then $\mathcal{F}_k^{-1}(\Psi_k)(E)$ is a Lagrangian state associated with the Lagrangian immersion $j_E : \Gamma^E \to M, (t, x) \mapsto x$, the section $s^E \in C^\infty(\Gamma^E, j_E^*L)$ given by $s^E(t, x) = e^{itE}s(t, x)$ and the principal symbol

$$\sigma^E(t, x) = B(t, x)^{-\frac{1}{2}} \sigma(t, x), \quad (t, x) \in \Gamma^E$$

where $\sigma$ is the principal symbol of $(\Psi_k)$ and $B(t, x)$ is such that $d\tau \wedge \alpha = iB(t, x) dt \wedge \alpha$ on $T_{(t, x)}\Gamma$ for any $\alpha \in K_x$, the square root $B(t, x)^{1/2}$ having a non negative real part.
We already explained that for a non-zero $\alpha \in K_x$, $dt \wedge \alpha$ is nonzero on $T_{(t,x)}\Gamma$. By the second assertion of Proposition 5.1, the same argument shows that $d\tau \wedge \alpha$ is non zero on $T_{(t,x)}\Gamma$ when $(t,x) \in \Gamma^E$. This proves that $B(t, x)$ is uniquely determined and nonzero as well.

**Proof.** Introduce a local unitary frame $u$ of $L$ and write $F(t, x) = e^{ij(t,x)}u(x)$, where $F$ is the section appearing in the definition (12) of $\Psi_k$. Then

$$
\mathcal{F}_k^{-1}(\Psi_k)(E)(x) = \left(\frac{k}{2\pi}\right)^\frac{d}{2} \int_{\mathbb{R}} e^{ik\phi(t,x)}a(t,x,k) \, dt
$$

with $\phi(t, x) = tE + f(t, x)$. The imaginary part of $\phi$ is nonnegative. It vanishes when $|F(t, x)| = 1$, that is when $(t, x) \in \Gamma$. We have

$$
\phi_t'(t, x) = E + f_t'(t, x), \quad \phi_{tt}''(t, x) = f_{tt}''(t, x).
$$

Here $g \mapsto g_t'$ means differentiation with respect to $t$.

We claim that the function $f_t'$ is an extension of $\tau$ such that $\overline{\partial}f_t'$ vanishes to infinite order along $\Gamma$. Indeed, by taking the restriction of $\nabla F$ to $\Gamma$, we obtain that $f_t' = \tau$ on $\Gamma$ (see also the argument in the proof of Proposition 2.2). Then since $\overline{\partial}F$ vanishes to infinite order along $\Gamma$, the same holds for $\overline{\partial}f + \overline{\partial}_u$, and by taking the derivative with respect to $t$, the same holds for $\overline{\partial}f_t'$.

So for $(t, x) \in \Gamma$, $\phi_t'(t, x) = 0$ if and only if $(t, x) \in \Gamma^E$. So by Lemma 7.7.1 in [15], if $(t_0, x_0) \notin \Gamma^E$, then the integral in (36) restricted to a neighborhood of $t_0$ is in $\mathcal{O}(k^{-\infty})$ on a neighborhood of $x_0$. So to estimate (36) on a neighborhood of a point $x_0$, it suffices to integrate on a neighborhood of $j_E^{-1}(x_0)$. Let $V$, $U$ be neighborhoods of $x_0$ and $t_0 \in j_E^{-1}(x_0)$ respectively such that $W = \Gamma^E \cap (U \times V)$ is a graph $\{(t(x), x), x \in j_E(W) \cap V\}$.

Since $f_t' = \tau$ and $\overline{\partial}f_t' = 0$ on $\Gamma$, we have $f_{tt}''dt + \partial f_t' = d\tau$ on $\Gamma$. Mutiplying by $\alpha \in \Omega^{n,0}(M)$, we get $f_{tt}''dt \wedge \alpha = d\tau \wedge \alpha$ on $\Gamma$. As explained before the proof, $d\tau \wedge \alpha$ does not vanish on $T_{t,x}\Gamma$, so $f_{tt}''$ does not vanish on $\Gamma^E$ and we can apply the stationary phase lemma for a complex valued phase, see [18, Theorem 2.3] or [15, Theorem 7.7.12]. This theorem implies that on a neighborhood of $j_E(W)$

$$
\left(\frac{k}{2\pi}\right)^\frac{1}{2} \int_U e^{ik\phi(t,x)}a(t,x,k) \, dt = e^{ik\phi_E(x)} \sum_{\ell=0}^N k^{-\ell} a_{E,\ell}(x) + \mathcal{O}(k^{-N-1})
$$

for any $N$, where

$$
\phi_E(x) = \phi(T(x), x), \quad a_{E,0}(x) = (-i\phi_t'(t, x))^{-\frac{1}{2}} a_0(T(x), x),
$$

27
the square root having a non negative real part. Here $T : U \to \mathbb{C}$ is an extension of $x \to t(x)$, that is $(T(x), x) \in \Gamma^E$ when $x \in j_E(W)$. The extension is chosen so that $\phi'_t(T(x), x) = 0$, where $\phi$ itself has been extended almost analytically to a neighborhood of $\mathbb{R} \times M$ in $\mathbb{C} \times M$. We claim that $F(x) = e^{i\phi_E(x)}u(x)$ is adapted to $(j_E(W), s^E|W)$. First if $x \in j_E(W)$, then

$$e^{i\phi(x)}u(x) = e^{it(E+E(x))}u(x) = e^{it}E_s(t(x), x) = s^E(t(x), x)$$

It remains to show that $\overline{\partial}F$ vanishes to infinite order along $j_E(W)$. Assume first that we can choose the section $F$ to be holomorphic, so that $\phi'_t$ depends holomorphically on $x$. If furthermore we can extend $\phi'_t$ so that it depends holomorphically on $t$, then by the holomorphic version of the implicit function theorem $T$ is holomorphic and $F$ is holomorphic as well. In general, we only know that $\overline{\partial}F$ vanishes to infinite order along $\Gamma$ and by adapting the previous argument, we conclude that $\overline{\partial}F$ vanishes to infinite order along $j_E(W)$.

With a similar proof, we can also show that the same holds for the coefficients: $\overline{\partial}a_E, t \equiv 0$ along $j_E(W)$ to infinite order. However, it is actually easier to use the following fact: $F^k \sum k^{-\ell}b_{\ell} = O(k^{-\infty})$ if and only if all the coefficients $b_{\ell}$ vanish to infinite order along $j_E(W)$. And here we know that $\overline{\partial}(F^k \sum k^{-\ell}a_E, t) = O(k^{-\infty})$ by differentiating (37) under the integral sign.

6 Spectral projector

Consider a self-adjoint operator $\hat{H}$ acting on a finite dimensional Hilbert space $\mathcal{E}$. Here it is important that $\hat{H}$ is time-independent. Introduce a smooth function $f : \mathbb{R} \to \mathbb{C}$ with smooth compactly supported Fourier transform $\hat{f}$. We will work with the unitary Fourier transform, so

$$\hat{f}(t) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-itE}f(E) dE, \quad f(E) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{itE} \hat{f}(t) dt$$

The second formula directly gives

$$f(h^{-1}(E - \lambda)) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{itE} e^{-i\frac{t}{h} \lambda} \hat{f}(t) dt$$

with $h$ and $\lambda$ two real parameters. Doing a spectral decomposition $\hat{H} = \sum \lambda \Pi_\lambda$ where the $\lambda$ and $\Pi_\lambda$ are the eigenvalues and spectral projectors,
and introducing the quantum propagator \( U_t = \exp(-it\hat{H}) = \sum e^{-it\lambda} \Pi_\lambda \), we obtain

\[
f(\hbar^{-1}(E - \hat{H})) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{\frac{iE}{\hbar}} U_t \hat{f}(t) \, dt
\]

We can apply this to our Toeplitz operator \((T_k : \mathcal{H}_k \to \mathcal{H}_k)\) with quantum propagator \( U_{k,t} \), which gives

\[
f(k(E - T_k)) = k^{-\frac{1}{2}} \mathcal{F}_k^{-1}(\hat{f}(t)U_{k,t})(E)
\]

If \( E \) is a regular value of the principal symbol \( H \) of \( T_k \), we deduce by Theorem 5.4 that the Schwartz kernel of this operator is a Lagrangian state. This will be done in Section 6.2 and will prove Theorem 1.2 of the introduction. Before that, we will consider the simpler case of a state \((\Psi_k \in \mathcal{H}_k)\):

\[
f \left( k(E - T_k) \right) \Psi_k = k^{-\frac{1}{2}} \mathcal{F}_k^{-1}(\hat{f}(t)\Psi_{k,t})(E)
\]

where \( \Psi_{k,t} \) is the solution of \((\frac{i}{\hbar}\partial_t + T_k)\Psi_{k,t} = 0\) with initial condition \( \Psi_k \).

### 6.1 Lagrangian state spectral decomposition

Let \( \Gamma_0 \) be Lagrangian submanifold of \( M \) and let \( H \) be an autonomous Hamiltonian with flow \( \phi_t \). Set \( \Gamma_t = \phi_t(\Gamma_0) \) and \( \Gamma = \{(t, x) \mid x \in \Gamma_t \} \). Let \( E \in \mathbb{R} \) be a regular value of the restriction of \( H \) to \( \Gamma_0 \) and define

\[
\Gamma^E = \{(t, x) \mid x \in \Gamma_t \cap H^{-1}(E) \}.
\]

This submanifold is the same as the submanifold \( \Gamma^E \) defined in (31) from a (local) flat section \( s_0 \) of \( L \to \Gamma_0 \), because the corresponding function \( \tau \) is the restriction of \( -H \) to \( \Gamma \), see (15). Furthermore our assumption on \( E \) is equivalent to the fact that \( -E \) is regular value of \( \tau \).

The computation of the symbol of \( f(k(E - T_k))\Psi_k \) in terms of the symbol of \( \Psi_{k,0} \) will amount to transform a volume element of \( \Gamma_0 \) into a volume element of \( \Gamma^E \). Let us explain this. We denote by \( X \) the Hamiltonian vector field of \( H \) and by \( X_x^\perp \omega \) the symplectic orthogonal of \( \mathbb{R}X_x \) in \( T_x M \). For any \((t, x) \in \Gamma^E\), the Lagrangian space

\[
\mathfrak{L}_{(t, x)} := \mathbb{R}X_x \oplus (T_x \Gamma_t \cap X_x^\perp \omega)
\]

is the image of \( T_{(t, x)}j_E \) with \( j_E : \Gamma^E \to M \) the projection \((t, x) \mapsto x \). Observe that \( X_x \) does not belong to \( T_x \Gamma_t \) because \( E \) is a regular value of \( H|_{\Gamma_0} \), so it a regular value of \( H|_{\Gamma_t} \) as well.
Assume now \( t = 0 \) and \((0, x) \in \Gamma^E\). Choose \( \eta \in T^*_x \Gamma_0 \) such that \( \omega(X, \eta) = 1 \). Then we have

\[
T^*_x \Gamma_0 = \mathbb{R} \oplus (T^*_x \Gamma_0 \cap X^1_x), \quad \mathcal{L}_{(0, x)} = \mathbb{R} X_x \oplus (T^*_x \Gamma_0 \cap X^1_x).
\]

Starting from \( v \in \det T^*_x \Gamma_0 \), we write \( v = \eta \wedge w \) with \( w \in \det(T^*_x \Gamma_0 \cap X^1_x) \) and we set \( v(0, x) := X_x \wedge w \in \det \mathcal{L}_{(0, x)} \). This definition makes sense because \( \eta \) is unique modulo \((T^*_x \Gamma_0 \cap X^1_x)\) so that \( w \) is unique. More generally, if \( t \) is any real and \((0, x) \in \Gamma^E\), we set \( v(t, x) := (T^*_x \phi_t)_* v(0, x) \in \det \mathcal{L}_{(t, \phi_t(x))} \), viewing \( T^*_x \phi_t \) as a map from \( \mathcal{L}_{(0, x)} \) to \( \mathcal{L}_{(t, \phi_t(x))} \). Equivalently

\[
v(t, x) = X_{\phi_t(x)} \wedge (T^*_x \phi_t)_* w.
\]

We now define a map \( \mathcal{E}_t'(x) : K_x \to K_{\phi_t(x)} \) for any \( x \in \Gamma_0 \cap H^{-1}(E) \) by

\[
(\mathcal{E}_t'(x)(\alpha))(v(t, x)) = -i \alpha(v), \quad \forall v \in \det T^*_x \Gamma_0.
\]

We define the function \( C'_t \) by the equality \( \mathcal{E}_t'(x) = C'_t(x) T^L_t(x) \).

**Proposition 6.1.** Let \((\Psi_k)\) be a Lagrangian state of \( M \) associated with \((\Gamma_0, s_0)\) with symbol \( \sigma_0 \in C^\infty(\Gamma_0, L^1)\), \((T_k)\) a self-adjoint Toeplitz operator with principal and subprincipal symbol \( H, H^{\text{sub}} \), and \( f \in C^\infty(\mathbb{R}) \) having a smooth compactly supported Fourier transform.

If \( E \) is a regular value of \( H^{[\Gamma_0]} \), then \( \Psi_k = k^{\frac{3}{2}} f((k(E - T_k)) \Psi_k \) is a Lagrangian state associated with the Lagrangian immersion \( j^E : \Gamma^E \to M \), the flat section \( s^E \) of \( j^*_E L \) given by \( s^E(t, \phi_t(x)) = T^L_t(x)s_0(x) \) and the symbol \( \sigma^E \in C^\infty(j^*_E L^1) \) defined as

\[
\sigma^E(t, \phi_t(x)) = \tilde{j}(t) C'_t(x)^{\frac{1}{2}} e^{\frac{i}{2} \int_0^t H^{\text{sub}}(\phi_r(x)) dr} T^L_t(x) \sigma_0(x).
\]

where the square root is chosen so as to be continuous and to have a positive real part at \( t = 0 \).

**Proof.** The solution of the Schrödinger equation with initial condition \( \Psi_k \) is described as a Lagrangian state associated with \((\Gamma, s(t, x) = \phi^L_t(x) s_0(x))\) in Theorem 2.4. Then \( \Psi_k \) is the \( k \)-Fourier transform of this solution (39), so by Theorem 5.4, it is a Lagrangian state associated with the immersion \( j_E : \Gamma^E \to M \) and the section \( s^E(t, x) = e^{itE} s(t, x) = T^L_t(x)s_0(x) \) because for an autonomous Hamiltonian, \( \phi^L_t = e^{-itH} T^L_t \), see (3).

It remains to check the formula for the principal symbol. By Proposition 2.6, we have to prove that \( C'_t(x) = \frac{C_t(x)}{B(t, \phi_t(x))} \) is \( \mathcal{E}_t'(x) = \frac{E_t(x)}{B(t, \phi_t(x))} \), with
$B$ the function of Theorem 5.4. Comparing the definitions (21) and (42) of $\mathcal{E}_t(x)$ and $\mathcal{E}'_t(x)$, we have to show that for any $\beta \in K_{\phi_t(x)}$ and $v \in \det(T_x \Gamma_0)$,

$$B(t, \phi_t(x)) = \frac{i \beta(v(t, x))}{\beta((T_x \phi_t)_x v)}$$

(43)

where $v(t, x)$ is as in Equation (41). Let us first explain the proof at $t = 0$. Recall that $v(0, x) = X_x \wedge w$ and $v = \eta \wedge w$. Now $B$ is defined by the relation $d\tau \land \beta = iB \, dt \land \beta$ on $\Gamma$ for every $\beta \in K$. We have

$$T_{(0,x)} = \mathbb{R}(1, X_x) \oplus \mathbb{R}(0, \eta) \oplus \{(0, \xi), \xi \in (T_x \Gamma_0) \cap X_x \perp \omega\}$$

and $d\tau(1, X_x) = 0$ so that $d\tau(0, \eta) = 1$ and $d\tau(0, \xi) = 0$ for any $\xi \in T_x \Gamma_0 \cap X_x \perp \omega$ by (32). So evaluating the relation $d\tau \land \beta = iB \, dt \land \beta$ on $(1, X_x) \land (0, \eta) \land \frac{1}{2} \wedge (0, \xi_2) \ldots \land (0, \xi_n)$ where $w = \xi_2 \wedge \ldots \wedge \xi_n$, we get

$$-\beta(X_x \wedge w) = iB(0, x)\beta(w \wedge w),$$

(44)

which gives (43). The proof for $t \neq 0$ is exactly the same where all the symplectic data $X_x$, $\eta$, $w$, $\Gamma_0$ are replaced by their image under $\phi_t$.

The last point is the determination of the square root: we have $(C_t'(x))^{1/2} = C_t(x)^{1/2}/B(t, \phi_t(x))^{1/2}$, with $C_0(x)^{1/2} = 1$ and the square root $B(t, x)^{1/2}$ has a non negative real part by Theorem 5.4. It is even positive as explained in Remark 6.2.

Remark 6.2. The quantity $C_0'(x) = B(0, x)^{-1}$ can be computed explicitly as follows. For $x \in H^{-1}(E) \cap \Gamma_0$,

$$B(0, x) = \|X_1\|^2 + i\omega(X_1, X_2)$$

(45)

where $X_x = X_1 + X_2$ with $X_1 \in j_x(T_x \Gamma_0)$ and $X_2 \in T_x \Gamma_0$. Recall that $X_x \notin T_x \Gamma_0$, so $\|X_1\|^2 \neq 0$.

Proof of (45). We set $\eta = \|X_1\|^2 j_x X_1$ and compute $B(0, x)$ from (44). On the one hand, $\beta$ being a $(n, 0)$ form, $\beta(X_1 \wedge w) = -i\beta(jX_1 \wedge w) = -i\|X_1\|^2 \beta(\eta \wedge w)$. On the other hand, $X_2 = \omega(X_1, X_2)\eta$ plus a linear combination of the $\xi_i$, so $X_2 \wedge w = \omega(X_1, X_2)\eta \wedge w$. Gathering these equalities we get

$$\beta(X_x \wedge w) = \left(\omega(X_1, X_2) - i\|X_1\|^2\right) \beta(\eta \wedge w)$$

and the conclusion follows.
6.2 Smoothed spectral projector

Recall that $(T_k)$ is a self-adjoint Toeplitz operator with principal symbol $H$ and subprincipal symbol $H^{\mathrm{sub}}$ and that $f \in C^\infty(\mathbb{R})$ has a smooth compactly supported Fourier transform.

**Theorem 6.3.** Let $E$ be a regular value of $H$. Then the Schwartz kernel of $f(k(E-T_k))$ is a Lagrangian state associated with the Lagrangian immersion $j_E : \Gamma^E \to M^2$, the flat section $s^E \in C^\infty(j^*\Gamma^E)$ and the symbol $\sigma^E \in C^\infty(j^*_xL')$ given by $\Gamma^E = \mathbb{R} \times H^{-1}(E)$, $j_E(t,x) = (\phi_t(x),x)$, $s^E(t,x) = T^E_t(x)$ and

$$\sigma_E(t,x) = \hat{f}(t)[\rho'_t(x)]^{\frac{1}{2}} e^{\frac{i}{2}\int_0^t H^{\mathrm{sub}}(\phi_t(x)) \, dr} T^E_t(x)$$

where the function $\rho'_t(x)$ is defined below.

Recall from the introduction the decomposition in symplectic subspaces $T_xM = F_x \oplus G_x$ where $F_x = \text{Vect}(X_x, j_x X_x)$ and $G_x = F^\perp_x$. $F_x$ and $G_x$ are both preserved by $j_x$ and we denote by $K(F_x), K(G_x)$ their canonical lines. We define

$$\Phi_F : K(F_x) \to K(F_{\phi_t(x)}), \quad \Phi_F(\lambda_x) = 2\|X_x\|^{-2} \lambda_{\phi_t(x)} \quad (46)$$

where $\lambda_x \in K(F_x)$ is normalised by $\lambda_x(X_x) = 1$. Furthermore $\Phi_G$ is the map $K(G_x) \to K(G_{\phi_t(x)})$ such that

$$\Phi_G(\alpha)(u) = \alpha(u), \quad \forall \alpha \in K(G_x), \forall u \in \wedge^n T_x M \quad (47)$$

where $\psi$ is the symplectic map $G_x \to G_{\phi_t(x)}$ induced by $T_x \phi_t$ and the isomorphism $G_x \simeq T_x H^{-1}(E)/\mathbb{R} X_x$.

Then we set $D'_t(x) := \Phi_F \otimes \Phi_G : K_x \to K_{\phi_t(x)}$ and we denote by $\rho'_t(x)$ the complex number such that

$$D'_t(x) = \rho'_t(x) T^K_t(x).$$

We denote by $[\rho'_t(x)]^{\frac{1}{2}}$ the continuous square root equal to $\sqrt{2\|X_x\|^{-1}}$ at $t = 0$.

**Proof.** This is a particular case of Proposition 6.1 just as Theorem 6.3 on the quantum propagator was a particular case of Theorem 2.4. Let us compute the coefficient $E'_t(x)(\text{id}_{K_x})$. We first describe the image (40) of $T_{(t,x)} j_E$:

$$\Sigma_{t,x} = \mathbb{R}(X_x,0) \oplus \{ (T_x \phi_t(\xi), \xi), \xi \in T_x H^{-1}(E) \}$$
and its volume (41). Set \( \eta = \|X_x\|^{-2}j_xX_x \) so that \((X_x, \eta)\) is a symplectic basis of \(F_x\). Let \((\xi_i)\) be a symplectic basis of \(G_x\). Then if the volume of \( \text{diag} T_x M \) is \( v = v_F \wedge v_G \) with

\[
v_F = (X_x, X_x) \wedge (\eta, \eta) , \quad v_G = (\xi_1, \xi_1) \wedge \ldots \wedge (\xi_m, \xi_m) ,
\]

then we have \( v(0, x) = -(X_x, 0) \wedge (X_x, X_x) \wedge (\xi_1, \xi_1) \wedge \ldots \wedge (\xi_m, \xi_m) \) so that

\[
v(t, x) = -(X_{\phi_t(x)}, 0) \wedge (X_{\phi_t(x)}, X_x) \wedge (T_x \phi_t(\xi_1), \xi_1) \wedge \ldots \wedge (T_x \phi_t(\xi_m), \xi_m)
\]

because \( T_x \phi_t(\xi) = \psi(\xi) \) modulo \( \mathbb{R} X_{\phi_t(x)} \). Then \( E_t(x)(\text{id}_{K_x}) = \Phi_F \otimes \Phi_G \) where \( \Phi_F : K(F_x) \to K(F_{\phi_t(x)}) \) is such that

\[
\langle \Phi_F, (X_{\phi_t(x)}, 0) \wedge (0, X_x) \rangle = i(\text{id}_{K(F_x)}, v_F),
\]

and \( \Phi_G : K(G_x) \to K(G_{\phi_t(x)}) \) is such that

\[
\langle \Phi_G, (\psi(\xi_1), \xi_1) \wedge \ldots \wedge (\psi(\xi_m), \xi_m) \rangle = (\text{id}_{K(G_x)}, v_G),
\]

Here the pairings are based on the identifications \( \text{Mor}(K(S), K(S')) \cong K(S') \otimes \overline{K(S)} \cong K(S' \oplus \overline{S}) \). Now \( \Phi_G \) is the application satisfying (47) by Lemma 4.1. And \( \Phi_F \) is the application (46) by a straightforward computation. \( \square \)

7 Proof of theorem 2.5

We choose complex normal coordinates \((z_i)\) of \( M \) centered at \( x_0 \in M \). So \( G_{ij}(x_0) = \delta_{ij} \) and \( \partial_{z_i} G_{jk}(x_0) = \partial_{\overline{z}_i} G_{jk}(x_0) = 0 \). We may assume that \( T_{x_0} \Gamma_{t_0} \) is spanned by the vectors \( \partial_{z_i} + \partial_{\overline{z}_i}, \ i = 1, \ldots, n \). Recall that \( Y \) is the vector field \((\partial_t, X_t)\) of \( I \times M \) where \( X_t \) is the Hamiltonian vector field of \( H_t \). Since \( \omega = i \sum_{j,k} G_{jk} dz^j \wedge d\overline{z}^k \), we have

\[
X_t = i \sum_{j,k} (-G^{jk} H_{z_j} \partial_{z_k} + G^{jk} H_{\overline{z}_k} \partial_{z_j}) \tag{50}
\]

where we use the notation \( H_{z_j} = \partial_{z_j} H_t \) and \( H_{\overline{z}_k} = \partial_{\overline{z}_k} H_t \) (and below we will use similar notation for higher order derivatives). As explained before the statement of Theorem 2.5, we have two derivatives \( \nabla_Y \) and \( \mathcal{L}_Y \) acting on \( (\mathbb{C} \otimes \mathcal{K})|_{\Gamma} \) in the same direction \( Y \), so \( \theta := \frac{1}{i}(\mathcal{L}_Y - \nabla_Y) \) is a function in \( C^\infty(\Gamma) \).
Proposition 7.1. \( \theta(x_0) = \sum_j (H_{z_j z_j}(x_0) + H_{z_j z_j}(x_0)) \)

Proof. Let \( \alpha = dz_1 \wedge \ldots \wedge dz_n \). First we have the section \( 1 \otimes \alpha \) of \( (\mathbb{C} \otimes K)|_x \) and we compute its covariant derivative with respect to \( Y \). We claim that this derivative vanishes at \( x_0 \). This follows from the fact that \( |\alpha|^2 = \det G_{i j} \), so the Chern connection of \( K \) (given near \( x_0 \) by the one-form \( \frac{\partial (|\alpha|^2)}{|\alpha|^2} \)) is zero at \( x_0 \) because the coordinates are normal at \( x_0 \). Second we have to compute the Lie derivative with respect to \( Y \) of \( j^*(dt \wedge \alpha) \) with \( j \) the embedding \( \Gamma \to I \times M \). We have \( L_Y j^*(dt \wedge \alpha) = j^*(L_Y (dt \wedge \alpha)) \). Furthermore \( L_{\partial_t} dt = L_{\partial_t} dz_i = 0 \) and by (50), we have

\[
L_{X_t} dz_j = d(X_t, z_j) = i \sum_k (H_{z_j z_k} dz_k + H_{z_k z_j} dz_k)
\]

at \( x_0 \) because the coordinates are normal. Furthermore \( j^*(dt \wedge dz_k) = j^*(dt \wedge dz_k) \) at \( x_0 \) by the assumption on \( T_{x_0} \Gamma_0 \). Collecting all these informations, we deduce that

\[
L_Y (j^*(dt \wedge \alpha)) = i \sum_j (H_{z_j z_j}(x_0) + H_{z_j z_j}(x_0)) j^*(dt \wedge \alpha)
\]

at \( x_0 \). The conclusion follows. \( \square \)

Introduce the Szegö projector \( \Pi_k \) which is the orthogonal projector of \( C^\infty(M, L^k \otimes L') \) onto \( \mathcal{H}_k \).

Proposition 7.2. For any Lagrangian state \( (\Psi_k) \) associated with \( \Gamma_{t_0} \) with symbol \( \sigma \) and any function \( f \in C^\infty(M) \), \( \Pi_k(f \Psi_k) \) is a Lagrangian state with symbol

\[
f|_{\Gamma_{t_0}} \sigma + h(\frac{1}{2} \nabla_{U_f}^L + \Box f) \sigma + O(h^2)
\]

where \( U \) is the vector field of \( \Gamma_{t_0} \) such that \( U(x) = X_f(x) \mod T_{x_0}^0 M \), \( X_f \) being the Hamiltonian vector field of \( f \), and \( \Box f = \sum_j (f_{z_j z_j} + \frac{1}{2} f_{z_j z_j}) \) at \( x_0 \).

Proof. We already know that \( \Pi_k(f \Psi_k) \) is a Lagrangian state associated with \( \Gamma_{t_0} \). We compute its symbol up to \( O(h^2) \) at \( x_0 \). It suffices to prove that this symbol has the form

\[
(c_0 + hc_1)f(x_0) \sigma(x_0) + h(\frac{1}{2} \nabla_{U_f}^L + \Box f) \sigma(x_0) + O(h^2)
\]

where \( c_0 \) and \( c_1 \) are independent of \( f \). Since for \( f = 1 \), we have to recover \( \sigma(x_0) \), \( c_0 = 1 \) and \( c_1 = 0 \) necessarily.
Besides our normal coordinates \((z_i)\) and our assumption on \(T_{x_0}\Gamma_{t_0}\), let us introduce two holomorphic normal frames \(v\) and \(v'\) of \(L\) and \(L'\) respectively. So \(|v| = e^{-\frac{r}{2}}\) with \(r\) a real function such that
\[
\varphi(x_0) = \partial_{z_j} \varphi(x_0) = \partial_{z_j} \partial_{z_k} \varphi(x_0) = 0, \quad \forall j, k.
\]
Similarly \(|v'| = e^{-\frac{r'}{2}}\) with \(r'\) satisfying the same conditions. Notice that the curvature of \(L\) is equal to both \(\partial \overline{\partial} \varphi\) and \(-i \omega\), so \(\partial_{z_i} \partial_{z_j} \varphi = G_{ij}\) for every \(i, j\). We can assume that \(v(x_0) = s(x_0)\) where \(s\) is the section over \(\Gamma_{t_0}\) associated with our Lagrangian state. In the rest of the proof we write all the sections of \(L^k \otimes L'\) in the frame \(v^k \otimes v'\).

More details on the computations to come can be found in [6, Sections 2.4, 2.5]. We have
\[
\Pi_k(x_0, x) = \left(\frac{k}{2\pi}\right)^n \int e^{k \psi(x) + \psi'(x)} p(x, k) + \mathcal{O}(k^{-\infty})
\]
where \(\psi\) has the following Taylor expansion at \(x_0\):
\[
\psi(x) = \sum_{\beta \in \mathbb{N}^n} \frac{x^\beta}{\beta!} \varphi_{0, \beta}
\]
with the notations \(\varphi_{0, \beta} = \partial_\beta \partial_{\overline{z}} \varphi(x_0)\), \(\psi'\) has the same Taylor expansion in terms of \(\varphi'\) and \(p(x, k) = 1 + k^{-1} p_1(x) + k^{-2} p_2(x) + \ldots\).

We have a similar expression for \(\Psi_k\):
\[
\Psi_k(x) = \left(\frac{k}{2\pi}\right)^{\frac{n}{2}} e^{k \rho(x) a(x, k)} + \mathcal{O}(k^{-\infty})
\]
where \(\rho\) has the Taylor expansion \(\rho(x) = \frac{1}{2} \sum z_i^2 + \sum_{|\alpha| > 3} \rho_{\alpha, 0} \frac{z^\alpha}{\alpha!}\). This follows from the fact that the section \(F\) entering in the definition (12) of \(\Psi_k\) satisfies \(F(x_0) = s(x_0)\) so that we can assume that \(\rho(x_0) = 0\), \(\nabla F |_{x_0} = 0\) so that the first derivatives of \(\rho\) all vanish at \(x_0\) and finally the second order derivatives of \(F\) at \(x_0\) depend only on the linear data at \(x_0\) [6, Proposition 2.2] which leads to the expression above.

So it comes that
\[
\Pi_k(f \Psi_k)(x_0) = \left(\frac{k}{2\pi}\right)^{\frac{n}{2}} \int e^{-k \phi} f(x) a(x, k) p(x, k) D(x) dz d\overline{z} + \mathcal{O}(k^{-\infty})
\]

(53)

where
\[
\phi(x) = -\psi(x) + \varphi(x) - \rho(x) = |z|^2 - \frac{1}{2} \sum z_i^2 + R(x)
\]
with \(R\) having the Taylor expansion at \(x_0\)
\[
R(x) = \sum_{\alpha \neq 0, \beta \neq 0, |\alpha| + |\beta| > 3, |\alpha| > 3} \varphi_{\alpha, \beta} \frac{z^\alpha z^\beta}{\alpha! \beta!} + \sum_{|\alpha| > 3} (-\rho_{\alpha, 0} + \varphi_{\alpha, 0}) \frac{z^\alpha}{\alpha!}.
\]

35
Furthermore $D(x) = e^{\psi(x) - \varphi(x)} \det(G_{ij}) = 1 + O(|z|^2)$.

By applying the stationary phase method, we obtain the asymptotic expansion of (53). At first order:

$$\Pi_k(f\Psi_k)(x_0) = C\left(\frac{k}{2\pi}\right)^{\frac{n}{2}} \left(f(x_0)a(x_0, k) + O(k^{-1})\right)$$

where $C$ can be computed in terms of the Hessian determinant of $\phi$ at $x_0$. Actually it is shorter to compare with (52), which gives $C = c_0 = 1$. We now compute the second order term,

$$\Pi_k(f\Psi_k)(x_0) = \left(\frac{k}{2\pi}\right)^{\frac{n}{2}} \left(f(x_0)a(x_0, k) + k^{-1}\varepsilon_k + O(k^{-2})\right)$$

with

$$\varepsilon_k = \sum_{\ell=1}^3 (\ell! (\ell - 1)!)^{-1} P^\ell((-R)^{\ell-1} f a(\cdot, k) D)(x_0)$$

where $P = \sum (\partial_{z_j} \partial_{\bar{z}_j} + \frac{1}{2} \partial_{\bar{z}_j} \partial_{z_j})$.

Recall that we do not try to compute the terms $c_0$ and $c_1$ in (52), which means that we do not take into account the terms without derivative on $a(x, k)$. Considering the form of the Taylor expansions of $R$ and $D$ given above and the fact that $\partial_{z_j} \partial_{\bar{z}_j} \varphi = G_{ij}$ so that $\varphi_{\alpha, \beta} = 0$ when $(|\alpha|, |\beta|) = (1, 2)$ or $(2, 1)$, we deduce after some investigations that we only have a single term to consider which is $k^{-1}P(f(x)a(x, k))$. Now $a(x, k) = a_0(x) + O(k^{-1})$ and $a_0$ has the Taylor expansion of a holomorphic function at $x_0$ because $\partial(a_0 v')$ vanishes to infinite order along $\Gamma_t^0$ and the frame $v'$ is holomorphic. So

$$P(f a_0) = (P f) a_0 + \sum_j (\partial_{\bar{z}_j} f)(\partial_{z_j} a_0). \quad (54)$$

The Hamiltonian vector field of $f$ at $x_0$ being $\sum_j (-i f z_j \partial_{\bar{z}_j} + i f \partial_{z_j} \partial_{\bar{z}_j})$ (see (50)), and by using again that $\partial_{\bar{z}} a_0 = 0$ at $x_0$, we obtain that the sum in (54) is $\frac{1}{i} X f a_0 = \frac{1}{i} U a_0$. Now the frame $v'$ being normal, its covariant derivative is 0 at $x_0$, so $\nabla_{\psi}(a_0 v') = (U a_0) v'$.

**Proof of Theorem 2.5.** It suffices to consider the case where $T_{k,t} = T_k(H_t + k^{-1}H'_t)$ for some $H_t, H'_t \in \mathcal{C}^\infty(M)$. But the symbol of $k^{-1}T_k(H'_t) \Psi_k$ is $h H'_t \sigma + \mathcal{O}(h^2)$, so in fact we only need to consider the case $H'_t = 0$.

By Proposition 7.2 and the proof of Proposition 2.2, the symbol of

$$\frac{1}{ih} \partial_t \Psi_k + T_k(H_t) \Psi_k$$

is

$$\frac{1}{h} (\nabla_Z + \nabla_U) \sigma + \mathcal{O}(h^2), \quad (55)$$
where \( Z \) and \( U \) are the vector fields of \( \Gamma \) such that \( Z(t,x) = \partial_t \) mod \( T_x^0,1 M \) and \( U(t,x) = X_t(x) \) mod \( T_x^0,1 M \). Since here \( Y(t,x) = (\partial_t, X_t) \) is tangent to \( \Gamma \), we have \( Z + U = Y \) on \( \Gamma \). By Proposition 7.1, \( \Box H_t = \frac{1}{2} \theta + \frac{1}{2} \Delta H_t \) with \( \Delta = \sum i,j G^{ij} \partial_i \partial_j \) (indeed, recall that the coordinates are normal at \( x_0 \) so \( \Delta H_t(x_0) = \sum_i H_z(z_i(x_0)) \)). So the symbol in (55) is

\[
 h(\frac{i}{\hbar} \nabla_Y + \frac{1}{2} \theta + \frac{1}{2} \Delta H_t) \sigma + O(h^2)
\]

which concludes the proof. \( \square \)

A Appendix: an explicit example

Let \((M, \omega) = (\mathbb{T}^2 = \mathbb{R}^2 / \Lambda, \omega_{\mathbb{T}^2})\) where \( \Lambda \subset \mathbb{R}^2 \) is a lattice of symplectic volume \( 4 \pi \). \((M, \omega)\) is naturally endowed with a prequantum line bundle \( L \) induced by the line bundle \( \mathbb{R}^2 \times \mathbb{C} \to \mathbb{R}^2 \) with connection \( \nabla = d - i \alpha \) where \( \alpha = 2 \pi (p \, dq - q \, dp) \). Here \((p, q)\) are coordinates associated with a basis \((e, f)\) of \( \Lambda \) with \( \omega(e, f) = 4 \pi \). In other words \( \omega = 4 \pi dp \wedge dq \); we will also work with the holomorphic coordinate \( z = p + i q \), for which \( \omega = 2i \pi dz \wedge d\bar{z} \).

For \( k \geq 1 \), the quantum space \( \mathcal{H}_k = H^0(M, L^k) \) identifies with the space of \( \Lambda \)-invariant sections of \( \mathbb{R}^2 \times \mathbb{C} \to \mathbb{R}^2 \), which is a space of theta functions with dimension \( 2k \). More precisely, the family \((\Psi_\ell)_{0 \leq \ell \leq 2k-1}\) given by

\[
 \Psi_\ell(z) = \frac{k^{\frac{1}{2}}}{\sqrt{2\pi}} \exp(2i\pi(\ell + k\Im(z))) \exp\left(-\frac{\pi \ell^2}{2k}\right) \vartheta_3(\pi(2kz + i\ell), \exp(-2k\pi))
\]

for all \( z \in \mathbb{C} \) and \( \ell \in \{0, \ldots, 2k-1\} \), where \( \vartheta_3(w, q) = 1 + 2 \sum_{n=-1}^{\infty} q^{n^2} \cos(2nw) \) is the Jacobi theta function, forms an orthonormal basis of \( \mathcal{H}_k \). The diagonal operator defined as \( T_k \Psi_\ell = \cos(\frac{\pi \ell}{k}) \Psi_\ell \) for every \( \ell \in \{0, \ldots, 2k -1\} \) is a Berezin-Toeplitz operator with principal symbol \( H : (p, q) \mapsto \cos(2\pi q) \) and vanishing subprincipal symbol. For more details, see [10, Section 3.1, Appendix].

On the one hand, one can easily compute numerically the kernel of the quantum propagator \( U_{k,t} = \exp(-iktT_k) \) by using the formula

\[
 U_{k,t}(w, z) = \sum_{\ell=0}^{2k-1} \exp\left(-ikt \cos\left(\frac{\pi \ell}{k}\right)\right) \Psi_\ell(w) \Psi_\ell(z)
\]

and the above expression of \( \Psi_\ell \) (in practice, we use the built-in commands for Jacobi theta functions in the mpmath library for Python). On the other hand, the coefficients in Equation (8) can be explicitly computed as follows.
Since the subprincipal symbol of $T_k$ vanishes, it suffices to compute $\rho_t$ and $\phi_t^L$. First, the parallel transport term reads

$$T_t^L(p, q) = \exp \left( i \int_0^t \alpha_{\phi_s(p, q)}(X(\phi_s(p, q))) ds \right) = \exp \left( -i \pi t q \sin(2\pi q) \right)$$

since $X(p, q) = \frac{1}{2} \sin(2\pi q) \partial_p$ and $\phi_t(p, q) = [p + \frac{t}{2} \sin(2\pi q), q]$, and we obtain

$$\phi_t^L(p, q) = \exp(-it \cos(2\pi q)) T_t^L(p, q) = \exp \left( -it \cos(2\pi q) + \pi q \sin(2\pi q) \right).$$

Second, one readily checks that $(T(p, q) \phi_t)^{1.0}$ is the operator of multiplication by $1 - \frac{i\pi t}{2} \cos(2\pi q)$. Since the connection on the canonical bundle is trivial, this yields

$$\rho_t(p, q) = \left( 1 - \frac{i\pi t}{2} \cos(2\pi q) \right)^{-\frac{1}{2}} = \exp \left( \frac{i}{2} \arctan \left( \frac{\pi t}{2} \cos(2\pi q) \right) \right) \frac{1}{\sqrt{1 + \frac{\pi^2 t^2}{4} \cos^2(2\pi q)}}.$$

So we finally obtain that for $z = p + iq$,

$$U_{k, t}(\phi_t(z), z) \sim \frac{k \exp \left( i \left( \frac{1}{2} \arctan \left( \frac{\pi t}{2} \cos(2\pi q) \right) - kt \cos(2\pi q) + \pi q \sin(2\pi q) \right) \right)}{2\pi \sqrt{1 + \frac{\pi^2 t^2}{4} \cos^2(2\pi q)}}.$$

(57)

We compare this theoretical equivalent with the numerical value in Figures 3, 1, 2, 4 and 5. In these computations, we fix $k$ and $(p, q)$, and plot the real part of the kernel of the propagator evaluated at $(\phi_t(z), z)$ with $z = p + iq$, as a function of $t$; we also plot the imaginary part of this kernel only for one set of parameters, since the behaviour is very similar to the one of real part. In all these figures, the blue diamonds represent the numerical values obtained from Equation (56) while the solid red line corresponds to the right hand side of Equation (57). Note that once $k$ and $(p, q)$ are fixed, we expect the approximation to become less precise as $t$ increases. This is clearly seen in Figure 5. However the approximation is extremely accurate for small times, as can be seen in Figure 4.
Figure 1: Real part of $U_{k,t}(\phi_t(z), z)$ for $k = 100$ and $z = p + iq$ with $(p, q) = (0.3, 0.1)$, for $0 \leq t \leq 1$.

Figure 2: Imaginary part of $U_{k,t}(\phi_t(z), z)$ for $k = 100$ and $z = p + iq$ with $(p, q) = (0.3, 0.1)$, for $0 \leq t \leq 1$. 
Figure 3: Real part of $U_{k,t}(\phi_t(z), z)$ for $k = 50$ and $z = p + iq$ with $(p, q) = (0.5, 0.7)$, for $0 \leq t \leq 1$.

Figure 4: Real part of $U_{k,t}(\phi_t(z), z)$ for $k = 100$ and $z = p + iq$ with $(p, q) = (0.3, 0.1)$, for $0 \leq t \leq 0.1$. 

40
Figure 5: Real part of $U_{k,t}(\phi_t(z), z)$ for $k = 100$ and $z = p + i q$ with $(p, q) = (0.3, 0.1)$, for $0.8 \leq t \leq 0.9$.
