Harmonic Elimination Strategy (HES) has been a widely researched alternative to traditional PWM techniques. This paper presents the harmonic elimination strategy of a Uniform Step Asymmetrical Multilevel Inverter (USAMI) using Particle Swarm Optimization (PSO) which eliminates specified higher order harmonics while maintaining the required fundamental voltage. This method can be applied to USAMI with any number of levels. As an example, in this paper a 13-level USAMI is considered and the optimum switching angles are calculated to eliminate the 5th, 7th, 11th, 13th and 17th harmonics. The HES-PSO approach is compared to the well-known Sinusoidal Pulse-Width Modulation (SPWM) strategy. Simulation results demonstrate the better performances and technical advantages of the HES-PSO controller in feeding an asynchronous machine. Indeed, the harmonic distortions are efficiently cancelled providing thus an optimized control signal for the asynchronous machine. Moreover, the technique presented here substantially reduces the torque undulations.

**Key words:** Uniform step asymmetrical multilevel inverter (USAMI), Harmonic Elimination Strategy (HES), Particle Swarm Optimization (PSO), Sinusoidal Pulse-Width Modulation (SPWM)

1 INTRODUCTION

Multilevel inverters have been widely used in last years for high-power applications [1]. Variable-speed drives have reached a wide range of standard applications such as pumps, fans and others. Many of these applications use medium-voltage motors (2300, 3300, 4160 or 6600 V), due to their lower current ratings in higher power levels [2]. Static Var compensators and active filters are other applications that use multilevel converters [3].

Several topologies of multilevel inverters have been studied and presented. Among them, neutral point clamped inverters [4], flying capacitors inverters also called imbricated cells [5], and series connected cells inverters also called cascaded inverters [6]. The industry often has used the neutral-point-clamped inverter [7]. However, the topology that uses series connected cells inverters presents some advantages, as smaller voltage rate \( \frac{dU}{dt} \) due to existence of higher number levels, producing less common-mode voltage across motor windings [8]. Furthermore, this topology is simple and its modular configuration makes it easily extensible for any number of desired output voltage levels. Three-phase multilevel converters based on series connected single phase inverters (partial cells) in each phase are studied in this work. A multilevel converter with \( k \) partial inverters connected in serial is presented by Fig. 1. In this configuration, each cell of rank \( j = 1 \ldots k \) is supplied by a dc-voltage source \( U_{di} \). The relationship between the number of series-connected single-phase inverters in
each phase and the number of output voltage levels generated by this topology, respectively $k$ and $N$, is given by:

$$N = 2k + 1,$$

in the case where there are equal voltages in all partial inverters.

In all the well-known multilevel converter topologies, the number of power devices required depends on the output voltage level needed [9]. However, increasing the number of power semiconductor switches also increases the converter circuit and control complexity and the costs. To provide a large number of output levels without increasing the number of converters, a uniform step asymmetrical multilevel inverters (USAMI) can be used [10].

The key issue in designing an effective multilevel inverter is to ensure that the Total Harmonic Distortion (THD) of the output voltage waveform is within acceptable limits. Harmonic Elimination Strategy (HES) has been intensively studied in order to achieve low THD [11]. The output voltage waveform analysis using Fourier theory produces a set of non-linear transcendental equations. The solution of these equations, if exists, gives the switching angles required for certain fundamental component and selected harmonic profile. Iterative procedures such as Newton-Raphson method has been used to solve these sets of equations [12]. This method is derivative-dependent and may end in local optima, and a judicious choice of the initial values alone guarantees conversion [13]. Another approach based on converting the transcendental equation into polynomial equations is presented in [14, 15], where resultant theory is applied to determine the switching angles to eliminate specific harmonics. That approach, however, appears to be unattractive because as the number of inverter levels increases, so does the degree of the polynomials of the mathematical model. This is likely to lead to numerical difficulty and substantial computational burden as well.

Genetic algorithms (GA) have been used to obtain optimal solutions for inverter circuits supplied from constant dc sources [16, 17]. Despite their effectiveness in harmonic elimination strategy, they are complicated and their parameters such as crossover and mutation probability, population size and number of generations are usually selected as common values given in literature or by means of a trial and error process to achieve the best solution set.

The Particle Swarm Optimization (PSO) [18] has the ability to combat the above drawbacks. As an optimization technique, PSO is much less dependent on the start values of the variables in the optimization problem when compared with the widely used Newton-Raphson or mathematical programming techniques such as Sequential Quadratic Programming (SQP). In addition, PSO does not rely on the guidance of the gradient information, such as the Jacobian matrix, hence it is more capable of determining the global optimum solution. PSO deal with all problems that usually considered very hard for researchers, such as integer variables, non-convex functions, non-differentiable functions, domains not connected, badly behaved functions, multiple local optima, and multiple objectives [19, 20]. For these reasons, PSO has been adopted in this study.

This paper presents an optimal minimization technique assisted with PSO algorithm in order to highly reduce the computational burden associated with the solution of the non-linear transcendental equations of the harmonic elimination strategy of a 13-level USAMI. The performance of this HES-PSO approach is evaluated and compared to the SPWM technique. The proposed HES-PSO strategy is also evaluated when the inverter supplies an asynchronous machine. In this application, it is important that the implemented controller computes appropriate switching angles for the inverters in order to minimize the harmonics absorbed by the asynchronous machine. Performances where successfully achieved, the HES-PSO controller demonstrates a satisfying behavior and a good robustness.

The paper is organized as follows. USAMIs are described and modeled in Section 2. Section 3 briefly introduces the well-known Sinusoidal PWM and brings out the original HES using PSO. Section 4 evaluates the proposed HES-PSO strategy in computing optimal angles of 13-level inverter used to supply an asynchronous machine. Results show that the HES-PSO method cancels the harmonic distortions and supplies the machine with a well-formed sinusoidal voltage waveform. In Section 5, we conclude with final remarks.
2 UNIFORM STEP ASYMMETRICAL MULTILEVEL INVERTER

Multilevel inverters generate at the ac-terminal several voltage levels as close as possible to the input signal. Fig. 2 for example illustrates the \( N \) voltage levels \( U_{s1}, U_{s2}, \ldots U_{sN} \) composing a typical sinusoidal output voltage waveform. The output voltage step is defined by the difference between two consecutive voltages. A multilevel converter has a uniform or regular voltage step, if the steps \( \Delta U \) between all voltage levels are equal. In this case the step is equal to the smallest dc-voltage, \( U_{d1} \) [10]. This can be expressed by

\[
|U_{sl} - U_{sl(t-1)}| = \Delta U = U_{d1}, \; l = 2 \ldots N \tag{1}
\]

If this is not the case, the converter is called a non uniform step AMI or irregular AMI. The control unit defines the switching function \( S_j \) of the power switches, and the output voltage is defined by

\[
U_s = \sum_{j=1}^{k} (S_j * U_{dj}) \text{ with } S_j \in \{-1, 0, +1\} \tag{2}
\]

where \( k \) represents the number of partial cells per phase. An USAMI is based on dc-voltage sources to supply the partial cells (inverters) composing its topology which respects to the following conditions:

\[
U_{d1} \leq U_{d2} \leq \ldots \leq U_{dk} \text{ and } U_{dj} \leq 1 + 2\sum_{l=1}^{j-1} U_{dl} \tag{3}
\]

The number of levels of the output voltage can be deduced from

\[
N = 1 + 2\sum_{j=1}^{k} \frac{U_{dj}}{U_{d1}} \tag{4}
\]

This relationship fundamentally modifies the number of levels generated by the multilevel topology. Indeed, the value of \( N \) depends on the number of cells per phase and the corresponding supplying dc-voltages.

The smallest dc-voltage \( U_{d1} \), which equals the uniform voltage step, is chosen as base value for the \( p.u. \) notation. The small letters are adopted for the \( p.u. \) values.

Equation (4) accepts different solutions. With \( k = 3 \) for example, there are two possible combinations of supply voltages for the partial inverters in order to generate a 13-level global output, i.e., \((u_{d1}, u_{d2}, u_{d3}) \in \{(1, 1, 4); (1, 2, 3)\}\), and there are three possible combinations to generate a 15-level global output, i.e., \((u_{d1}, u_{d2}, u_{d3}) \in \{(1, 1, 5); (1, 2, 4); (1, 3, 3)\}\). The output voltages of each partial cells of the 13-level inverter with \( u_{d1} = 1 \; p.u., \; u_{d2} = 2 \; p.u. \) and \( u_{d3} = 3 \; p.u. \) are noted \( u_{p1}, u_{p2} \) and \( u_{p3} \) and can take three different values: \( u_{p1} \in \{-1, 0, 1\}, u_{p2} \in \{-2, 0, 2\} \) and \( u_{p3} \in \{-3, 0, 3\} \). The result is a generated output voltage with 13 levels: \( u_s \in \{-6, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 6\} \). Some levels of the output voltage can be generated by different commutation sequences. For example, there are three possible commutation sequences resulting in \( u_s = 2 \; p.u. : \; (u_{p1}, u_{p2}, u_{p3}) \in \{(-1, 0, 3); (1, -2, 3); (0, 2, 0)\}\). These redundant combinations can be selected in order to optimize the switching process of the inverter [21].

These different possibilities offered by the output voltage of the partial inverters, and the redundancies among them to deliver a same output voltage level, can be considered as degrees of freedom which can be exploited in order to optimize the use of a AMI.

3 MULTILEVEL INVERTERS CONTROL STRATEGIES

Among several modulation strategies, the multi-carrier sub-harmonic PWM technique has been receiving an increasing attention for symmetrical multilevel converters [10]. This modulation method can also be used to control asymmetrical multilevel power converters. Other kinds of modulation techniques can also be used in the case of AMIs [22].

This section briefly presents the sinusoidal PWM technique. We also propose a HES based on PSO. These control strategies will be compared by computer simulations. The objective is to elaborate optimized switching angles for a 13-level USAMI in order to supply an asynchronous machine.
3.1 Sinusoidal Pulse-Width Modulation (SPWM)

The SPWM is also known as the multi-carrier PWM because it relies on a comparison between a sinusoidal reference waveform and vertically shifted carrier waveforms. \(N - 1\) carriers are therefore required to generate \(N\) levels. The carriers are in continuous bands around the zero reference. They have the same amplitude \(A_c\) and the same frequency \(f_c\). The sine reference waveform has a frequency \(f_r\), and an amplitude \(A_r\). At each instant, the result of the comparison is 1 if the triangular carrier is greater than the reference signal and 0 otherwise. The output of the modulator is the sum of the different comparisons which represents the voltage level. The strategy is therefore characterized by the two following parameters [23], respectively called the modulation index and the modulation rate:

\[
m = \frac{f_c}{f_r} \tag{5}
\]

\[
r = \frac{2}{N - 1} \frac{A_r}{A_c} \tag{6}
\]

We propose to develop a 13-level inverter composed of \(k = 3\) partial inverters per phase with the following dc-voltage sources: \(u_d1 = 1\) p.u., \(u_d2 = 2\) p.u. and \(u_d3 = 3\) p.u.. For output voltage frequency \(f = 50\) Hz, the output voltages \(u_{p1}\), \(u_{p2}\) and \(u_{p3}\) of each partial inverter and \(u_a\), the phase \(a\) voltage, are represented by Fig. 3 with \(m = 19\) and \(r = 0.9\). The harmonic content of \(u_a\) is calculated using the Fast Fourier Transform (FFT) and it is represented by Fig. 4.

3.2 Harmonics Elimination Strategy with PSO

3.2.1 Harmonics Elimination Strategy (HES)

The HES is based on the Fourier analysis of the generated voltage \(u_a\) at the output of the USAMI (see Fig. 2) [22]. This voltage is symmetric in a half and a quarter of a period. As a result, the even harmonic components are zero. The sine reference waveform has a frequency \(f = 50\) Hz, the output voltage frequency \(f = 50\) Hz, \(m = 19\) and \(r = 0.9\). The harmonic content of \(u_a\) is calculated using the Fast Fourier Transform (FFT) and it is represented by Fig. 4.

\[
u_a = \sum_{n=1}^{\infty} u_n \sin(n\omega t), \quad \text{with} \quad u_n = \frac{4u_{di}}{n\pi} \sum_{i=1}^{p} \cos(n\theta_i) \tag{7}
\]

where \(u_n\) is the amplitude of the harmonic term of rank \(n\), \(p = (N - 1)/2\) is the number of switching angles per quarter waveform, and \(\theta_i\) is the \(i^{th}\) switching angle.

The \(p\) switching angles in (7) are calculated by fixing the amplitude of the fundamental term and by canceling the \(p - 1\) other harmonic terms. Practically, six switching angles \(\theta_1, \theta_2, \ldots, \theta_6\) are necessary for canceling the five first harmonics terms (i.e., harmonics with a odd rank and non multiple of 3, therefore 5, 7, 11, 13 and 17) in the case of a three phase 13-level USAMI composed of \(k = 3\) partial inverters per phase supplied by the dc-voltages \(u_d1 = 1\) p.u., \(u_d2 = 2\) p.u. and \(u_d3 = 3\) p.u.. These switching angles can be determined by solving the following system.
of non linear equations:

\[
\begin{align*}
\sum_{i=1}^{p=6} \cos(\theta_i) &= \frac{6\pi}{r} r \\
\sum_{i=1}^{6} \cos(n\theta_i) &= 0 \text{ for } n \in \{5, 7, 11, 13, 17\}
\end{align*}
\]

where \( r = u_1/6u_{d3} \) is the modulation rate. The solution of (8) must also satisfy

\[0 < \theta_1 < \theta_2 < \theta_3 < \theta_4 < \theta_5 < \theta_6 < \frac{\pi}{2}\] (9)

An objective function is then needed for the optimization procedure, which is selected as a measure of effectiveness of eliminating selected order of harmonics while maintaining the fundamental component at a pre-specified value. Therefore, this objective function is defined as:

\[F(\theta_1, \theta_2, \ldots \theta_6) = \left( \sum_{i=1}^{p=6} \cos(\theta_i) - \frac{6\pi}{r} \right)^2 + \sum_{n=5, 7, 11, 13, 17} \left( \sum_{i=1}^{p=6} \cos(n\theta_i) \right)^2\] (10)

The optimal switching angles are obtained by minimizing Eq. (10) subject to the constraint (9), and consequently the required harmonic profile is achieved. The main challenge is the non-linearity of the transcendental set of Eq. (8), as most iterative techniques suffer from convergence problems and other techniques such as elimination using resultant and GA are complicated.

3.2.2 Particle Swarm Optimization (PSO)

Particle swarm optimization is an intelligent algorithm which relies on exchanging information through social interaction among particles. The PSO conducts searches using a swarm of particles randomly generated initially. Each particle \(i\) (1 to swarm size) possesses a current position \(p_i = [p_{i1} p_{i2} \ldots p_{iq}]\) and a velocity \(v_i = [v_{i1} v_{i2} \ldots v_{iq}]\), \(q\) is the dimension of search space. The position of the particle represents a possible solution of the problem. The velocity indicates the change in the position from one step to the next. Each particle memorizes its personal best position \((p_{best_i})\) which corresponds to the best objective function value in the searched places. Each particle can also access to the global best position \((g_{best})\) that is the overall best place found by one member of the swarm. Namely, particles profit from their own experiences and previous experience of other particles during the exploration, to adjust their velocity, in direction and amount [24, 25]. The concept of a moving particle is illustrated in Fig. 5.

The velocity of each particle can be updated iteratively according to the following rule:

\[v_i(j+1) = w v_i(j) + c_1 r_1 (p_{best_i} - p_i(j)) + c_2 r_2 (g_{best} - p_i(j))\] (11)

where \(v_i(j)\) is the current velocity of particle \(i\) at iteration \(j\) and \(p_i(j)\) is the current position of particle \(i\) at iteration \(j\).

The inertia weight \(w\) governs how much of previous velocity should be retained from the previous time step. The acceleration coefficients \(c_1 > 0\) and \(c_2 > 0\) influence the maximum size of the step that a particle can take in a single iteration. \(r_1\) and \(r_2\) are two independent random sequences uniformly distributed in \([0, 1]\). These sequences are used to affect the stochastic nature of the algorithm.

The first term of right-hand side of the velocity update equation is the inertia velocity of particle, which reflects the memory behaviour of particle. The second term in the velocity update equation is associated with cognition since it only takes into account the private thinking and own experiences of particles. This component is a linear attraction toward the local best position ever found by the given particle. But the third term in the same equation represents the social collaboration and interaction between the particles. This component is a linear attraction toward the global best position found by any particle.

Each particle investigates the search space from its new local position using the following equation:

\[p_i(j+1) = p_i(j) + v_i(j)\] (12)

After a number of iterations, the particles will eventually cluster around the area where fittest solutions are.

3.2.3 Implementation of PSO for HES

In order to describe the implementation of the PSO in harmonic elimination strategy of a USAMI, the following algorithm is adopted.
Control of a Uniform Step Asymmetrical 13-Level Inverter Using Particle Swarm Optimization
R. Taleb, A. Meroufel, A. Massoum

Step 1: Initialization
for each particle:
- Initialize the position $\theta_i(0) = [\theta_{i1}(0) \ \theta_{i2}(0) \ldots \ \theta_{ip}(0)]$ of each particle with random angles that respect the constraint (9);
- Initialize the velocity $v_i(0) = [v_{i1}(0) \ v_{i2}(0) \ldots v_{ip}(0)]$ of each particle to random values;
- Initialize the best objective function $F_{pbest_i}$ of particle $i$. end for
- Initialization of the best objective function $F_{gbest}$ of the swarm. Loop

{ }

for each particle
Step 2: Objective function evaluation
- Compute the $f_i$ value of each particle $i$ of the swarm using the cost function given by (10);
Step 3: Personal best position updating
if $F_i < F_{pbest_i}$
then $F_{pbest_i} = F_i$ and $\theta_{pbest_i} = \theta_i$
end if
Step 4: Global best position updating
if $F_i < F_{gbest}$
then $F_{gbest} = F_i$ and $\theta_{gbest} = \theta_i$
end if
end for
for each particle
Step 5: Position and velocity updating
$v_{i}(q) = w v_{i}(p) + c1 r_1 (\theta_{pbest_i} - \theta_i) + c2 r_2 (\theta_{gbest} - \theta_i)$
$\theta_i = \theta_i + v_{i}(q)$
end for

Until a sufficiently good objective function value is reached.

This algorithm was used to find the switching angles for each phase in the case of a 13-level USAMI. The parameters selected for the implementation of PSO are: the population size $= 35$ particles, $w = 0.8$ and $c1 = c2 = 1.9$. The results for phase $a$ are plotted in Fig. 6 versus $r$.

As the plots show, for $r$ in the intervals $[0.587, 0.636]$, $[0.674, 0.967]$ and $[0.993, 1.044]$ as well as $r = 0.514, 1.082$, the output waveform can have the desired fundamental with the 5th, 7th, 11th, 13th, 17th harmonics absent. Further, in the subintervals $[0.674, 0.725]$, $[0.770, 0.802]$ and $[0.827, 0.916]$ two sets of solutions exist while in the subintervals $[0.687, 0.700]$ and $[0.770, 0.795]$ there are three sets of solutions. In the case of multiple solution sets, one would typically choose the set that gives the lowest THD by

$$\text{THD} = \sqrt{\sum_{n=5,7,...}^{\infty} \left( \frac{1}{n} \sum_{i=1}^{p} \cos(n\theta_i) \right)^2}$$

(13)

The even and third harmonic and its multiple are not computed in THD because do not appear in the line-to-line voltage $u_{ab}$.

The THD corresponding to the solutions given in Fig. 6 is represented by Fig. 7. Selecting the switching angles that lead to the lowest THD results in the solutions given by Fig. 8. The corresponding THD is shown on Fig. 9.

As seen on Fig. 10, any solution that yields a cost function less than 0.0001 is accepted. We clearly notice that the number of solutions for each $r$ increases or decreases in according to precision constraint value by which solutions are calculated.

AUTOMATIKA 55(2014) 1, 79–89
Control of a Uniform Step Asymmetrical 13-Level Inverter Using Particle Swarm Optimization

R. Taleb, A. Meroufel, A. Massoum

In order to evaluate the performance and the robustness of the proposed approach, a 13-level USAMI is used to

which corresponds to \( \theta_1 = 14.4440^\circ \), \( \theta_2 = 22.8530^\circ \), \( \theta_3 = 35.9015^\circ \), \( \theta_4 = 52.4221^\circ \), \( \theta_5 = 58.5196^\circ \) and \( \theta_6 = 65.8310^\circ \) (see Fig. 8). The relationship among the switching angles of the output voltage can be found as follows: in the second quarter \( \theta_j = \pi - \theta_i \) \((j = 7 \ldots 12), \ i = 6 \ldots 1\), in the third quarter \( \theta_j = \pi + \theta_i \) \((j = 13 \ldots 18), \ i = 1 \ldots 6\) and in the fourth quarter \( \theta_j = 2\pi - \theta_i \) \((j = 19 \ldots 24), \ i = 6 \ldots 1\). Fig. 12 shows the frequency content of \( u_a \) which can be compared to Fig. 4 obtained with the SPWM. This figure shows that the 5th, 7th, 11th, 13th and 17th harmonics are absent from the waveform as predicted. The triple harmonics (3th, 6th, 9th, etc.) in each phase do not need be canceled as they are automatically cancelled in the line-to-line voltage \( u_{ab} \). The THD of \( u_{ab} \) was computed and was found to be 4.19\% which compares favourably with the value of 4.17\% predicted with Fig. 9.

4 PERFORMANCE IN SUPPLYING AN ASYNCHRONOUS MACHINE

In order to evaluate the performance and the robustness of the proposed approach, a 13-level USAMI is used to
Control of a Uniform Step Asymmetrical 13-Level Inverter Using Particle Swarm Optimization

R. Taleb, A. Meroufel, A. Massoum

supply an asynchronous machine with the following data: rated power = 1 MW, rated voltage = 800 V, rated current = 620 A, rated speed = 850 rpm, stator resistance $R_s = 0.228 \Omega$, rotor resistance $R_r = 0.332 \Omega$, stator inductance $L_s = 0.0084 \ H$, rotor inductance $L_r = 0.0082 \ H$, mutual inductance $L_{mr} = 0.0078 \ H$, number of pole pairs $P = 3$, rotor inertia $J = 20 \ kg.m²$, viscous friction coefficient $K_f = 0.008 \ Nm.s.rad^{-1}$. The voltage for each separated dc source is: $U_{d1} = 150 \ V$, $u_{d2} = 300 \ V$ and $U_{d3} = 450 \ V$.

The HES-PSO is compared to the SPWM strategy in controlling the 13-level USAMI. The objective is to use the proposed PSO strategy in order to minimize the harmonics absorbed by the asynchronous machine.

The results of the control based on the SPWM are presented by Fig. 13 and Fig. 14. This first figure shows the stator current and the electromagnetic torque with significant fluctuations. The second figure shows the frequency content of the stator current. Results by using PSO approach of the HES are presented by Fig. 15 and Fig. 16. By comparing Fig. 14 to Fig. 16, it can be deduced that the HES-PSO efficiently cancels the harmonics of ranks 5, 7, 11, 13 and 17 from the output voltage $u_a$. Moreover, the amplitudes of the harmonic distortions are very small compared to the amplitude of the fundamental component.

Performances obtained with both methods are summarized in Table 1.

The THD measured on $u_a$ and resulting from the PSO approach of the HES is smaller than the one obtained with the SPWM method. The THD measured on the stator current $i_{as}$ is reduced by a factor 2.11 with the HES-PSO compared to the SPWM method. The control is thus optimized with the HES-PSO in order to avoid the asynchronous machine to absorb harmonics.

### Table 1. Performances of the control methods

| Control method | $u_a$ (THD) (%) | $i_{as}$ (THD) (%) | $f_{Te}$ (Hz) | $\Delta T_e$ (Nm) | nb of switch. | freq. ($\Delta f$) |
|----------------|----------------|------------------|--------------|-----------------|--------------|-----------------|
| SPWM          | 9.43           | 3.57             | $f$          | 579.4           | 38           | 1900            |
| HES-PSO       | 6.11           | 1.69             | $2f$         | 212.9           | 24           | 1200            |

The THD measured on $u_a$ and resulting from the PSO approach of the HES is smaller than the one obtained with the SPWM method. The THD measured on the stator current $i_{as}$ is reduced by a factor 2.11 with the HES-PSO compared to the SPWM method. The control is thus optimized with the HES-PSO in order to avoid the asynchronous machine to absorb harmonics.

### Slika 12. Frequency content of the phase a voltage $u_a$ with the HES-PSO strategy (with $f = 50 \ Hz$ and $r = 0.9$)

### Slika 13. Stator current (top) and electromagnetic torque (bottom) of the asynchronous machine fed by a 13-level USAMI controlled by the SPWM

### Slika 14. Frequency content of the stator current of the asynchronous machine fed by a 13-level USAMI controlled by the SPWM

It can also be seen that the electromagnetic torque continuously oscillates at a frequency $f$ ($f$ is the output voltage frequency of the inverter = 50 Hz) with the SPWM method (because of the harmonics of rank 2 and 4 which
are present in the output voltage). The torque oscillates at 2f with the HES-PSO approach. The HES-PSO method also reduced the number of switching angles and switching frequency by a factor 1.58 compared to the SPWM method which is highly appreciated for the electronic devices.

5 CONCLUSION

In this paper, a novel strategy to eliminate harmonics in USAMIs has been described which exploits the swarm intelligence. Particle swarm optimization is used to improve the harmonic elimination technique for USAMIs, which exhibits clear advantages in term of low switching frequency and high output quality. This study has shown that the particle swarm optimization is more suitable for 13-level USAMI optimal control design. This optimization algorithm is simple to implement, effective and inexpensive in term of memory and time required. The proposed HES-PSO approach is compared to the SPWM strategy. Simulation results are given to show the high performance and technical advantages of the PSO implementation of the HES for the control of a uniform step asymmetrical 13-level inverter. The HES-PSO approach is used to feed an asynchronous machine. The harmonic distortions are efficiently cancelled and the torque undulations are thus significantly reduced.

Rachid Taleb was born in Chlef, Algeria, in 1974. He received the M.S. degree in electrical engineering from the Hassiba Benbouali University, Chlef, Algeria, in 2004 and the Ph.D. degree in electrical engineering from the Djillali Liabes University, Sidi Bel-Abbes, Algeria, in 2011. He is currently an Associate Professor at the Department of Electrical Engineering, Hassiba Benbouali University. He is a member in the ICEPS (Intelligent Control Electrical Power System) Laboratory. His research interests include intelligent control, heuristic optimization, control theory of converters and converters for renewable energy sources.

Abdelkader Meroufel was born in Sidi Bel-Abbes, Algeria, in 1954. He received the M.S. degree in electrical engineering from the Mohamed Boudaif University of Science and Technology, Oran, Algeria, in 1990 and the Ph.D. degree in electrical engineering from the Djillali Liabes University, Sidi Bel-Abbes, Algeria, in 2004. He is currently Professor at the Department of Electrical Engineering, Djillali Liabes University. He is a team leader in the ICEPS (Intelligent Control Electrical Power System) Laboratory. His field of research includes intelligent control, converters control techniques, power electronics and electric machine control.

Ahmed Massoum was born in Tlemcen, Algeria, in 1959. He received the M.S. degree and the Ph.D. degree in electrical engineering from the Djillali Liabes University, Sidi Bel-Abbes, Algeria, in 2004 and 2007, respectively. He is currently an Associate Professor at the Department of Electrical Engineering, Djillali Liabes University. He is a member in the ICEPS (Intelligent Control Electrical Power System) Laboratory. His current research interests are artificial neural networks and intelligent control techniques.
