PERVERSE BUNDLES AND CALOGERO-MOSER SPACES

DAVID BEN-ZVI AND THOMAS NEVINS

Abstract. We present a simple description of moduli spaces of torsion-free \( D \)-modules (\( D \)-bundles) on general smooth complex curves, generalizing the identification of the space of ideals in the Weyl algebra with Calogero-Moser quiver varieties. Namely, we show that the moduli of \( D \)-bundles form twisted cotangent bundles to moduli of torsion sheaves on \( X \), answering a question of Ginzburg. The corresponding (untwisted) cotangent bundles are identified with moduli of perverse vector bundles on \( T^*X \), which contain as open subsets the moduli of framed torsion-free sheaves (the Hilbert schemes \( T^*X^{[n]} \) in the rank one case). The proof is based on the description of the derived category of \( D \)-modules on \( X \) by a noncommutative version of the Beilinson transform on \( \mathbb{P}^1 \).

1. Introduction

The starting point for this paper is the following. Let
\[
M = \mathfrak{gl}_n \times \mathfrak{gl}_n \times \mathbb{C}^n \times (\mathbb{C}^n)^* = T^*(\mathfrak{gl}_n \times \mathbb{C}^n).
\]
Define a map \( \mu : M \to \mathfrak{gl}_n \) by \( \mu(X, Y, i, j) = [X, Y] + ij \). It is well known (see e.g. [N]) that the geometric invariant theory quotient (at a nontrivial character \( \chi \), the determinant character of \( GL_n \))
\[
(\mathbb{C}^2)^{[n]} = \mu^{-1}(0) \sslash \chi GL_n
\]
is the Hilbert scheme of \( n \) points on \( \mathbb{C}^2 \). Indeed, stability forces \( j \) to vanish and \( i \in \mathbb{C}^n \) to generate \( \mathbb{C}^n \) under multiplication by \( X \) and \( Y \), so \( \mu^{-1}(0) \) parametrizes commuting \( n \times n \) matrices \( X, Y \) with a cyclic vector for \( \mathbb{C}[X, Y] \); hence \( \mu^{-1}(0) \sslash GL_n \) parametrizes length \( n \) quotients of \( \mathbb{C}[x, y] \).

Now consider the spaces
\[
CM_n = \mu^{-1}(I) / GL_n,
\]
known as the \( n \)-particle rational Calogero-Moser (CM) spaces. The CM spaces arise in the study of integrable systems and soliton equations [W]; they also play a central role in the representation theory of Cherednik algebras [EG]. We write \( A_1 = D_{A_1} = \mathbb{C}[x, \partial/\partial x] \) for the first Weyl algebra. There is an appealing generalization by Berest and Wilson [W, BW1, BW2] (following earlier work of Cannings-Holland [CH1] and Le Bruyn [LB]) of the above description of the Hilbert scheme to the classification of ideals in \( A_1 \):

**Theorem 1.1** ([BW1, BW2]). The space \( CM_n \) parametrizes (isomorphism classes of) right ideals in \( A_1 \) that “have second Chern class \( n \).”

It is tempting to think that the meaning of the theorem is transparent, since the CM relation \( \mu(X, Y, i, j) = I \), that is, \( [X, Y] + ij = I \), is very close to the defining relation \( [x, \partial/\partial x] = 1 \) for \( A_1 \). However, the equation \( [X, Y] = I \) for \( n \times n \) matrices
has no solutions, so the naive generalization of the description of the Hilbert scheme fails.

The relations between Hilbert schemes, Calogero-Moser spaces and the Weyl algebra have been further explored in many works. These include \cite{KKO, BGK1, BGK2, BN}, and, most notably for the present paper, \cite{BC}, where $CM_n$ was described via $A_\infty$-modules over $A_1$. In \cite{KKO}, the moduli spaces of (framed) modules of any rank over $A_1$ were described and related to the classical (ADHM quiver) description of moduli of torsion-free sheaves on $\mathbb{C}^2$ (framed at infinity), the Berest-Wilson theorem being the case of rank one; in \cite{BGK1, BGK2}, the corresponding moduli spaces for a more general class of “noncommutative planes” were identified with quiver varieties.

In light of the importance of the CM spaces, one naturally wants to generalize the description of ideals in $A_1 = \mathcal{D}_{A_1}$ to that of torsion-free modules over differential operators on a higher genus curve (the special case of elliptic curves was treated in \cite{BN} by methods that do not generalize to higher genus). As we indicated already, the space $M$ with which we started is the cotangent bundle of $Q_n = \mathfrak{gl}_n \times \mathbb{C}^n$. Furthermore, $Q_n$ is identified with a type of Quot scheme: it is the moduli space of quotients $O_{\mathbb{A}^1} \to Q$, where $Q$ is a torsion sheaf on the affine line of length $n$ equipped with a section $i \in H^0(Q)$. Finally, $\mu$ is identified with a moment map for the $GL_n$-action on $M = T^*Q_n$. With this in mind, Ginzburg proposed:

**Definition 1.2** (Ginzburg). Let $X$ be a smooth curve and $Q_n(X)$ the variety parametrizing pairs $(O_X^n \to Q, i \in H^0(Q))$ where $Q$ is a length $n$ torsion sheaf on $X$. The $n$th CM space of $X$, denoted $CM_n(X)$, is the Hamiltonian reduction of $T^*Q_n(X)$ at $i \in \mathfrak{gl}_n = \mathfrak{gl}_n^*$. The following theorem answers a question of Ginzburg asking for the higher-genus generalization of Theorem 1.1

**Theorem 1.3.** The space $CM_n(X)$ is the “Hilbert scheme of the quantized cotangent bundle of $X$,” i.e. the moduli space for trivially-framed $D$-line bundles (Definition 2.11 and Proposition 2.12) on $X$ with second Chern class $n$.

Our method, which we outline below, gives as a byproduct a quite transparent description of the procedures that identify rank 1 torsion-free $A_1$-modules with quadruples $(X, Y, i, j)$ satisfying the CM relation as an application of Koszul duality.

In fact, we prove a significantly more general result. Let $V$ denote a fixed vector bundle on $X$. Let $PS(X, V)$ denote the perverse symmetric power of the curve $X$; this is the moduli stack of framed torsion sheaves on $X$. i.e. pairs $(Q, i)$, where $Q$ is a torsion coherent sheaf on $X$ and $i: V \to Q$ is a homomorphism. The substack where the length of $Q$ is $n$ is denoted $PS_n(X, V)$. The terminology is motivated by the embedding of the symmetric powers $\text{Sym}^n X \to PS(X, \mathcal{O})$ as the locus where $i$ is surjective (i.e. where the complex $\mathcal{O} \to Q$ has no first cohomology).

A perverse vector bundle on the compactification $S = \mathbb{P}(T_X \oplus \mathcal{O}_X)$ of $T^*X$ is a coherent complex $\mathcal{F}$ on $S$ with $H^0(\mathcal{F})$ torsion-free, $H^1(\mathcal{F})$ zero-dimensional and all other cohomology sheaves vanishing (Definition 2.11); it is $V$-framed if its restriction to the divisor $\mathbb{P}(T_X \oplus \mathcal{O}_X) \setminus T^*X \cong X$ is equipped with a quasi-isomorphism to $V$. A $D$-bundle on $X$ is a torsion-free $D$-module on $X$, which one may consider as a torsion-free sheaf on the quantized cotangent bundle to $X$. A $V$-framing on a $D$-bundle is the noncommutative analog of fixing the behavior of a torsion-free sheaf on $T^*X$ near the curve at infinity in $S$. Technically it amounts to a filtration
of a prescribed form—a precise definition is given in Definition 2.11 below (which, by Proposition 2.12 agrees with our previous definition in [BN1]).

Theorem 1.4.

1. The cotangent bundle of the perverse symmetric power PS(X, V) is the moduli stack PB(X, V) of V-framed perverse vector bundles on T*X.

2. The Calogero-Moser space CM(X, V), defined as the twisted cotangent bundle (see [BB]) of PS(X, V) associated to the dual determinant line bundle, is isomorphic to the moduli stack of V-framed D-bundles on X.

Moreover, the components of CM and PB over PSn(X, V) parametrize D-bundles (respectively perverse bundles) with second Chern class c2 = n.

The reader may wish to view Theorem 1.4 in analogy with a well-known description of the moduli of flat vector bundles on X. Let Bun(X) denote the moduli stack of rank n vector bundles on X. The cotangent bundle T*X Bun(X) is identified with the moduli stack of Higgs bundles on X, which are coherent sheaves on T*X which are finite of degree n over X. On the other hand, the moduli space of rank n bundles with flat connection is the twisted cotangent bundle of Bun(X) corresponding to the dual of the determinant line bundle, i.e. the space of connections on this bundle (see for example [Fa, BZB]). This twisted cotangent bundle is not “supported” everywhere: for a bundle to admit a connection, all its indecomposable summands must have degree zero, so the image in Bun(X) of this twisted cotangent bundle is a proper subset of Bun(X). However, it carries a canonical action of the cotangent bundle and is a torsor for T*X Bun(X) over its image in Bun(X)—which we refer to as its support—making it a pseudo-torsor over its support.

Let us spell out more explicitly the meaning of part (2) of Theorem 1.4. Let PS(X, V) denote the (Quot-type) scheme parametrizing (Q, i) as above together with an identification Γ(Q) = Cn (this scheme is actually a smooth variety). The Calogero-Moser space CM(X, V) is given by hamiltonian reduction by GLn of the cotangent bundle of PS(X, V), with moment map given by the dual to the determinant character det ∈ gln*. This is a pseudo-torsor for the cotangent bundle of PS(X, V), i.e. a torsor over the locus of its support. One can show that the support of CM(X, V) → PS(X, V) is the substack of indecomposable framed torsion sheaves.

The moduli stack PBn(X, O^k) contains the moduli of framed rank k torsion-free sheaves on T*X, as the open subset of perverse bundles with vanishing first cohomology. In particular, in the rank one case we find that the Hilbert scheme of n points on T*X is an open subset of the moduli of the perverse Hilbert scheme:

(T*X)[n] ⊂ PBn(X) = T*PSn(X)

(where we drop the trivial framing from the notation). In the case of A^1, the perverse Hilbert scheme is the Hamiltonian reduction µ^{-1}(0)/GL_n, i.e. we have an open embedding

(C^2)[n] ⊂ PBn(A^1) = T^*([gl_n × C^n]/GL_n]

obtained by dropping the stability condition for the GIT quotient.

On the other hand, Theorem 1.4 asserts in particular that the moduli of (trivially framed c2 = n) D-bundles is the pseudo-torsor CMn(X) over the perverse Hilbert scheme PBn(X) = T*PSn(X). Moreover, if Pic(X) is trivial, rank one O_X-framed
\(D\)-bundles up to isomorphism correspond to isomorphism classes of ideals in \(D\). For \(X = \mathbb{A}^1\), we thus recover the intimate relationship between Calogero-Moser spaces, ideals in the Weyl algebra and the Hilbert scheme of points in the plane that appears in the numerous works cited above.

1.1. Techniques and Outline. We will deduce Theorem 1.4 from a general description of arbitrary framed \(D\)-modules on (not necessarily projective) smooth curves \(X\) (in particular, of general holonomic \(D\)-modules and \(D\)-bundles), generalizing a classical description of flat vector bundles (which are precisely \(D\)-modules framed by 0). As we review in Section 2, framed \(D\)-modules on \(X\) and framed sheaves on \(T^*X\) are both examples of sheaves on noncommutative \(\mathbb{P}^1\)-bundles (i.e. noncommutative ruled surfaces) over \(X\), in the sense of \([\text{vdB}2]\). In order to describe sheaves on a \(\mathbb{P}^1\)-bundle, it is natural to imitate the Beilinson transform description of complexes on projective spaces, or equivalently to apply Koszul duality. This technique was first applied to give a description of \(D\)-bundles on projective curves by Katzarkov, Orlov and Pantev \([\text{KOP}]\). We build on this idea to prove a general derived equivalence (Theorem 1.5) from which we deduce descriptions of various classes of objects (Theorems 1.6 and 1.7).

As an important technical note, we work throughout not with derived categories of modules as triangulated categories, but rather with differential graded (dg) categories which are “enhancements” of underlying (triangulated) derived categories. See \([\text{Ke}3]\) for an excellent overview and Section 2.2 for more discussion of the framework we need.

In Section 2, we develop the general algebraic setting we need for noncommutative \(\mathbb{P}^1\)-bundles, by localizing the category of graded modules for the Rees algebra \(R(D)\) with respect to bounded modules (the usual construction of \text{Qgr} \(R(D)\)). We also introduce the dg derived category, denoted \(\text{D}_{dg}(\mathbb{P}D)\), of this localized module category. In Section 3, we adapt the Beilinson transform to our setting and develop an analog of Čech cohomology for computing its output. We then prove, in Section 4, that the Beilinson transform gives a concise description of \(\text{D}_{dg}(\mathbb{P}D)\): it is equivalently described as a dg category of Koszul data (Section 4.1). An object \(M \in \text{D}_{dg}(\mathbb{P}D)\) has a well-defined “restriction to the curve at infinity” \(i_\infty^* M\), and we may specialize the general Koszul description to framed complexes:

**Theorem 1.5.** (Theorem 4.3) There is a natural quasi-equivalence of dg categories between \(\text{D}_{dg}(\mathbb{P}D)\) and the dg category \(\text{Kos}\) of Koszul data (see Section 4.7) whose objects are triples \(C = (C_{-1}, C_0, a : D^1 \otimes C_{-1} \rightarrow C_0)\) consisting of objects \(C_{-1}\) and \(C_0\) of \(\text{D}_{dg, \text{qcoh}}(X)\) together with a morphism \(a : D^1 \otimes C_{-1} \rightarrow C_0\) of complexes.

Under this quasi-equivalence, a choice of \(V\)-framing of an object \(M\) of \(\text{D}_{dg}(\mathbb{P}D)\) corresponds to a choice of quasi-isomorphism \(\text{Cone}(C_{-1} = O \otimes C_{-1} \xrightarrow{a} C_0) \simeq V\) for the corresponding object \((C_{-1}, C_0, a)\) of \(\text{Kos}\).

An identical result holds in the commutative case, i.e. for complexes on \(T^*X\), with \(D^1\) replaced by \(O \oplus \mathcal{T}\): this is just the families version of the usual description of the derived category of \(\mathbb{P}^1\), and the same methods can be extended to the noncommutative setting. Furthermore, the difference of two \(D^1\)-action maps \(a_1, a_2\) as above gives their commutative analog, thereby explicitly exhibiting a pseudotorsor structure for framed \(D\)-complexes over framed complexes on \(T^*X\). This is one of the

\(^1\)Alternatively, one may use the Koszul duality between modules for the Rees algebra and for the de Rham algebra \([\text{Kap}]\) to describe \(\text{D}_{dg}(\mathbb{P}D)\).
main points of our paper: that the standard Beilinson description of sheaves on the projective line, with straightforward modifications, provides an explicit description of the moduli of $\mathcal{D}$-modules on curves generalizing and clarifying the much-studied case of the Weyl algebra.

Next, in Section 4, we identify which objects in $\text{Kos}$ correspond to honest framed $\mathcal{D}$-modules, rather than complexes. Derived categories of surfaces carry a natural perverse coherent $t$-structure, obtained from the standard $t$-structure by tilting the torsion sheaves of dimension zero into cohomological degree one $^2$ A similar definition makes sense for the noncommutative ruled surface defined by $\mathcal{D}$-modules; however, since there are no $\mathcal{D}$-modules with zero-dimensional support, this recovers the standard $t$-structure. As might be expected from the interpretation as a Koszul duality or de Rham functor, it is the perverse $t$-structure which is compatible with the Beilinson transform description above. In particular we find that the commutative analog of the data describing $\mathcal{D}$-modules parametrizes (framed) perverse coherent sheaves on $T^*X$.

The equivalence of Theorem 1.5 simplifies considerably in the case of $\mathcal{D}$-bundles, i.e., the case of pure two-dimensional support. Suppose the framing $V$ is a vector bundle. Then, under the quasi-equivalence of Theorem 1.5 a $V$-framed perverse $\mathcal{D}$-bundle corresponds to a triple $(C_{-1}, C_0, a)$ in which $C_{-1} = Q[-1]$ where $Q$ is a torsion sheaf on $X$, and $C_0 = \text{Cone}(V \xrightarrow{i} Q)$ for a map $i$. We thus obtain:

**Theorem 1.6** (Theorem 4.6). For a vector bundle $V$ on $X$, the moduli stack $\text{CM}(X,V)$ is isomorphic to the stack of triples $(Q, i, a)$ where $Q$ is a torsion sheaf, $i : V \to Q$ is a homomorphism, and

$$a : Q[-1] \to \text{Cone}(V \xrightarrow{i} Q)$$

is a map in $D_{dg,\text{qcoh}}(X)$.

The corresponding commutative data give perverse vector bundles on $T^*X$. More generally, let

$$0 \to \mathcal{O}_X \to \mathcal{E} \to \mathcal{E}/\mathcal{O}_X \to 0$$

be an exact sequence of vector bundles on $X$, with $\text{rk}(\mathcal{E}) = 2$. Let $S = \mathbb{P}(\mathcal{E})$ with the section $\sigma$ determined by $\mathcal{O}_X \subset \mathcal{E}$.

**Theorem 1.7.**

1. The moduli stack of $V$-framed perverse vector bundles on $S$ (framed along the section $\sigma$) is isomorphic to the moduli stack of triples $(Q, i, a)$ where $(Q, i)$ is a framed torsion sheaf and

$$a : \mathcal{E} \otimes Q[-1] \to \text{Cone}(V \xrightarrow{i} Q)$$

is a map whose restriction to $\mathcal{O} \otimes Q[-1]$ is the natural "inclusion."

2. In particular, the conclusion of Theorem 4.6 holds for $\text{PB}(X,V)$, with $\mathcal{D}^1$ replaced by $\mathcal{O} \oplus T_X$.

**Remark 1.8 (Holonomic modules).** It is easy to read off from Theorem 1.5 the analog of the above classification in the case of holonomic $\mathcal{D}$-modules, i.e. the case of pure one-dimensional support. More precisely, for a torsion sheaf $V$ on $X$, the moduli stack of $V$-framed (hence holonomic) $\mathcal{D}$-modules is isomorphic to the stack of triples $(C_{-1}, C_0, a)$ as in Theorem 1.5 where $C_{-1}$ is a vector bundle (in degree $^2$ A $t$-structure on a dg category is just a $t$-structure on its derived category (Section 2.2).
zero) and $C_0$ is an extension of $V$ by $C_{-1}$. The same data, with $D^1$ replaced by $O \otimes T_X$, describes the moduli stack of $V$-framed coherent sheaves on $T^*X$ with pure one-dimensional support—these are precisely the framed spectral sheaves on $T^*X$, as described in [KOP, BN2].

The resulting descriptions are evidently functorial and local in $X$ (in other words, we describe framed $\mathcal{D}$-modules and perverse coherent sheaves as stacks over $X$). When the curve is projective, Serre duality then identifies the perverse coherent data $(Q, i, a)$ with the cotangent bundle to the underlying coherent data $(Q, i)$, so that the moduli stacks of framed $\mathcal{D}$-modules all form pseudotorsors over the cotangent bundles to certain moduli spaces of complexes of coherent sheaves on the curve.

A key calculation takes place in Section 5, where we identify the space of Koszul data for $\mathcal{D}$-bundles with a specific twisted cotangent bundle to the stack of framed torsion sheaves. We show that the relevant twist comes from the dual determinant bundle (resulting in Theorem 1.3). To prove this, we use the natural description of the cotangents to quot schemes to identify the Calogero-Moser moment condition with the Leibniz rule governing the action map $a$ in the Koszul data. This calculation can be carried over to describe the moduli space of flat vector bundles or general holonomic $\mathcal{D}$-modules as twisted cotangent bundles associated to dual determinant bundles; we hope to investigate this realization further in future work.

We conclude in Section 6 by spelling out very explicitly the dictionary between our data and the usual CM data on the affine line.

1.2. Acknowledgments. The authors are deeply indebted to Victor Ginzburg for generously sharing his ideas. We would also like to thank Misha Finkelberg, from a lecture of whose the authors learned of the role of perverse coherent sheaves in the ADHM classification.

The methods used in the present paper were inspired by two sources. One of these is the approach of Berest and Chalykh [BC] to modules over the Weyl algebra (using $A_{\infty}$-modules over free algebras). Indeed, one of the goals of this paper is to place their work in a general dg context and bypass the explicit use of free algebras, making possible our generalization to arbitrary (complexes of) $\mathcal{D}$-modules on curves. The authors are grateful to Yuri Berest for very helpful discussions of [BC].

A second source for the methods used here is the unpublished work of Katzarkov-Orlov-Pantev [KOP]. We are deeply grateful to Tony Pantev for teaching us how to use Koszul duality and related methods, and to Katzarkov-Orlov-Pantev for sharing [KOP] with us.

2. Noncommutative $\mathbb{P}^1$-Bundles and Perverse Bundles

2.1. Preliminaries on Algebras and Noncommutative $\mathbb{P}^1$-Bundles. Fix a smooth quasi-projective complex curve $X$.

**Notation 2.1.** Let $D^1$ denote a bimodule extension of the tangent sheaf $T = T_X$ of $X$ by $O_X$ of one of the following two sorts:

1. $D^1$ is a Lie algebroid on $X$, i.e. a sheaf of twisted first-order differential operators $D^1(L^{<c})$ on some line bundle $L$ on $X$ (where $c \in \mathbb{C}$).
2. $D^1$ is supported scheme-theoretically on the diagonal $\Delta \subset X \times X$, so it is just given by an extension of vector bundles on $X$. 
Remark 2.2. Our choice of $D^1$ above is more restrictive than that required for Theorem 1.7. However, it is easy to see that all the proofs needed for Theorem 1.7 work with $D^1$ replaced by a commutative bimodule $E$ as in the statement of the theorem. The hypotheses on $D^1$ chosen above are intended to make statements and proofs easier to follow in the cases of greatest interest.

In case (1), we let $D$ denote the universal enveloping algebroid of $D^1$, i.e. $D(D^1)$; in case (2), we let $D$ denote the quotient $\text{Sym}(D^1)/(1-1)$ of the symmetric algebra of $D^1$ by the relation that $1 \in \text{Sym}(D^1) = O$ equals $1 \in \text{Sym}(D^1) = D^1$. This is a filtered $O_X$-algebra (warning: $O_X$ is not necessarily a central subalgebra of $D$!) with associated graded algebra isomorphic to $\text{Sym}(T_X)$ and with $D^1$ as the first term in its filtration. Some examples: if $D^1$ is first-order differential operators then $D$ is the sheaf of differential operators $\mathcal{D}_X$; if $D^1 = D^1(L)$, then $D$ is the sheaf $D_X(L)$ of differential operators acting on sections of $L$; if $D^1 = O_X \oplus T_X$ (the split extension) then $D$ is the sheaf $O_{T^*X}$ of functions on the cotangent bundle of $X$.

Let
\[ \mathcal{R} = \mathcal{R}(D) = \sum_n D^n t^n \subset D[t] \]
denote the Rees algebra of $D$; this is a graded algebra with a central element $t \in \mathcal{R}$ of degree 1 such that $\mathcal{R}/t\mathcal{R} \cong \text{gr}(D)$. In particular, $\mathcal{R}$ is a graded $\mathbb{C}[t]$-algebra. The localization $\mathcal{R}[t^{-1}] \cong D \otimes \mathbb{C}[t, t^{-1}]$ is also a graded ring and we have the localization functor $\ell : \mathcal{R} \rightarrow \text{mod} \rightarrow \mathcal{R}[t^{-1}] \rightarrow \text{mod}$. Any modules over graded rings that we consider will always be assumed to be graded modules.

We let $E$ denote the (formal) microlocalization of $D$, see e.g. [AVV]; it is obtained by formally adding to $D$ power series in negative powers of vector fields. For example, if $T_X$ is trivial with nonvanishing section $\partial$, then $E \cong E_X((\partial^{-1}))$. The ring $E$ is also a filtered ring that contains $D$ as a filtered subring. Note that $E$ is not quasicoherent. Given a (left) $D$-module $M$, we let $M_E = E \otimes D M$, which we call (slightly abusively) the microlocalization of $M$; similarly, given an $\mathcal{R}$-module $N$, we let $N_{\mathcal{R}(E)} = \mathcal{R}(E) \otimes_\mathcal{R} N$ denote its microlocalization, which is a graded $\mathcal{R}(E)$-module.

Lemma 2.3. The localization and microlocalization functors $\ell$ and $(-)_{\mathcal{R}(E)}$ are exact; their right adjoints are the forgetful functors back to $\mathcal{R} \rightarrow \text{mod}$.

Proof. For microlocalization this is Theorem 3.19(2) and Corollary 3.20 of [AVV]. The statements about adjoints are standard. \qed

Remark 2.4. As in Section 7 of [BN1], if $M$ is a filtered $D$-module then $M_E$ comes equipped with a “canonical” filtration.

Example 2.5. Suppose $D^1 = O_X \oplus T_X$ with the central $O_X$-bimodule structure. Then $D = \pi_* O_{T^*X}$ (where $\pi : T^*X \rightarrow X$ the projection) is the symmetric algebra of the tangent sheaf and $\mathcal{R}$ is the homogeneous coordinate ring of the ruled surface
\[ \mathbb{P}_D := \text{Proj} \mathcal{R} = \mathbb{P}(T^*X \oplus O). \]
This is the union of $\text{Spec}D = T^*X$ and of a copy of the curve $X = \text{Proj}(R/tR)$ “at infinity”. The ring $\mathcal{E}$ is the ring of formal Laurent series with poles along the section $X \subset \mathbb{P}_D$. 

More generally, we will use $R$ to construct a noncommutative $\mathbb{P}^1$-bundle as follows. Let $\text{Gr } R$ denote the category of graded left $R$-modules that are quasi-coherent as $O$-modules, and let $\text{gr } R$ denote its full subcategory of locally finitely generated modules. We let $\text{Tors } R$ denote the full subcategory of $\text{Gr } R$ whose objects are irrelevant or locally bounded modules: a module $M$ is irrelevant if for every local section $m$ of $M$ there is some $n_0 \in \mathbb{Z}$ such that for all $n \geq n_0$ and all local sections $r$ of $R_n$, one has $r \cdot m = 0$. Geometrically, irrelevant modules are supported set-theoretically at the irrelevant ideal of $R$. Similarly, $\text{tors } R$ is the full subcategory of $\text{gr } R$ consisting of irrelevant modules.

The subcategories $\text{Tors } R$ and $\text{tors } R$ are Serre subcategories of $\text{Gr } R$ and $\text{gr } R$, respectively, and hence the quotient categories, denoted $\text{Qcoh}(\mathbb{P}_D) = \text{Qgr } R$ and $\text{Coh}(\mathbb{P}_D) = \text{qgr } R$, exist and have reasonable properties [AZ1, VdB1].

Remark 2.6. We will use the notation $\text{Qcoh}, \text{Coh}$ to emphasize the relationship with derived categories in the commutative world, since this relationship is absolutely central to our point of view.

As usual, there is an adjoint pair of functors

$$(\pi : \text{Gr } R \to \text{Qcoh}(\mathbb{P}_D), \quad \omega : \text{Qcoh}(\mathbb{P}_D) \to \text{Gr } R)$$

such that the adjunction $\pi \omega \to \text{Id}$ is an isomorphism. Here $\pi$ is exact and $\omega$ is left-exact.

By Theorem 8.8 of [AZ1] (using the element $t \in R$), $R$ satisfies the $\chi$-condition; it follows that Serre’s finiteness theorem for cohomology (Theorem 7.4 of [AZ1]) holds for $R$. Moreover, $R$ is strongly noetherian.

All the constructions above sheafify over $X$; in particular, $\text{Qgr } R$ forms a sheaf of abelian categories in the Zariski topology of $X$.

Remark 2.7. It is occasionally useful to work algebraically over affine open subsets of $X$: given an affine open subset $U \subset X$, we may work with the ring of global sections $R(U)$ and carry out the usual constructions for this ring. In particular, we will use this at one point later (the proof of Proposition 3.12).

2.2. DG Derived Categories. As we mentioned in the introduction, we work throughout not with derived categories of modules as triangulated categories, but rather with differential graded (dg) categories which are “enhancements” of underlying derived categories. For an excellent overview of dg categories we refer the reader to [Ke3]; detailed treatments of localization of dg categories can be found also in [D] and [To]. See also [Lu] for the foundations (including a discussion of $t$-structures) of the theory of stable $\infty$-categories, of which dg categories are the rational case, and [BLR] for properties of pretriangulated dg categories (those whose homotopy categories are triangulated).

There are natural dg versions of essentially all natural constructions with derived categories, the main technical difference being the need to sometimes consider dg categories up to quasi-equivalence rather than equivalence (see the above references as well as [Ta]). The localization construction for dg categories of Keller, Drinfeld and Toën (which is a dg analogue of Dwyer-Kan simplicial localization) allows one for example to take the dg category of complexes in an abelian category and localize it with respect to quasi-isomorphisms, resulting in a canonical dg category whose homotopy category is the usual derived category; we refer to this canonical dg enhancement as “the dg derived category.” Another quasi-equivalent dg enhancement
may be obtained from the dg category of injective complexes (see the discussion in [BLL]).

There are numerous technical advantages in working with dg enhancements of derived categories rather than with triangulated categories. Among these we single out three that we use below. First, the dg enhancements of derived categories satisfy a homotopical form of descent (or sheaf property) over the Čech nerve of a covering (see e.g. Section 7.4 of [BD] or Section 21 of [HS]). Second, one can recover moduli spaces of sheaves from the dg enhanced derived category [TV]. Finally, dg categories are amenable to explicit description as modules over the endomorphisms of a compact generator (see [Ke2] and the discussion of Theorem 4.3 below). Since we work uniformly throughout the paper with dg enhancements, we will often abuse terminology and refer simply to derived categories.

**Definition 2.8.** Let $D_{dg}(P_{D})$ denote the dg enhancement of the bounded derived category $D^b(Q\text{gr}\ R)$ obtained by localizing the dg category of complexes in $Q\text{gr}\ R$ with respect to the class of quasi-isomorphisms [Ke3, D, To]. We let $D_{dg, coh}(P_{D})$ denote the full dg subcategory of $D_{dg}(P_{D})$ whose objects have cohomologies in $q\text{gr}\ R$.

**Remark 2.9 (Calculating in DG Categories).** The reader who is unfamiliar with the yoga of dg categories may rest assured that such familiarity is mostly unnecessary for this paper. Indeed, although the dg derived category is essential for Theorem 4.3 and for the “families” part of Theorem 4.6, the proofs—and, especially, the calculations of objects—depend only on calculations involving cohomologies and so can be understood in the usual (triangulated) derived category.

Note that one has an equivalence $Q\text{gr}(\text{Sym} T_\mathcal{X}) \simeq Q\text{coh}(X)$. It follows that one has a base-change functor

$$i_\infty^*: Q\text{coh}(P_{D}) = Q\text{gr}\ R \to Q\text{gr}\ R/tR \simeq Q\text{coh}(X)$$

and an induced base-change functor $i_\infty^*$ on derived categories. Both of these functors may be applied to objects of the abelian category $Q\text{gr}\ R$, and we will write $Li_\infty^*$ for the derived functor applied to such objects. There is also a “direct image” functor $(i_\infty)_*$.  

**2.3. Perverse Bundles.** We continue to assume that $X$ and $D$ are as in the previous section. An object $M$ of $\text{coh}(P_{D})$ is said to be **zero-dimensional** if

(a) the graded $\mathcal{R}$-module $\omega M$ has zero-dimensional support on $X$, and

(b) the Hilbert function $h_{\omega M}(k) = \text{length}(\omega(M)_k)$ is a bounded function of $k$.

We let $\mathcal{T}$ denote the full subcategory of $\text{coh}(P_{D})$ consisting of zero-dimensional objects. We let $\mathcal{F}$ denote the full subcategory of $\text{coh}(P_{D})$ consisting of objects that have no nonzero zero-dimensional subobjects. For every object $N$ of $\text{coh}(P_{D})$, there is a unique maximal zero-dimensional subobject $t(N)$ obtained by forming the sum $T(\omega N) \subset \omega N$ of all graded $\mathcal{R}$-submodules of $\omega N$ that have properties (a) and (b) above and taking the subobject $t(N) = \pi(T(\omega N)) \subset N$. We thus obtain an exact sequence in $q\text{gr}\ R$,

$$0 \to t(N) \to N \to N/t(N) \to 0$$

with $t(N) \in \mathcal{T}$ and $N/t(N) \in \mathcal{F}$. The pair $(\mathcal{T}, \mathcal{F})$ forms a torsion pair in $q\text{gr}\ R$, then, and we have:
Proposition 2.10 (Prop. I.2.1 of [HRS] or Prop. 2.5 of [Br2]). The full subcategory \(\mathcal{P}\) of \(D_{dg}(\mathbb{P}_D)\) given by

\[
\mathcal{P} = \{ E \in D_{dg}(\mathbb{P}_D) \mid H^i(E) = 0 \text{ for } i \notin \{0,1\}, H^0(E) \in \mathcal{F}, H^1(E) \in \mathcal{T}\}
\]

is the heart of a bounded t-structure on \(D_{\text{dg,coh}}(\mathbb{P}_D)\).

Note that by definition a t-structure on a pretriangulated dg category (i.e. one whose homotopy category is triangulated, [BLL]) is a t-structure on its homotopy category.

We will refer to an object of \(\mathcal{P}\) as a perverse \(\mathcal{R}\)-module. An object \(N\) of \(Qcoh(\mathbb{P}_D)\) is said to be torsion-free if it has the form \(\pi(M)\) for some torsion-free module \(M\) in \(Gr \mathcal{R}\). It follows from [AZ1 S2, p. 252] that in this case \(\omega N\) is a torsion-free graded \(\mathcal{R}\)-module.

Let \(V\) be a vector bundle on \(X\).

Definition 2.11. A \(V\)-framed complex of \(\mathcal{D}\)-modules is an object \(M\) of the dg derived category \(D_{dg}(\mathbb{P}_D)\) equipped with an isomorphism \(i_{\Delta}^*(M) \to V\). A \(V\)-framed perverse \(\mathcal{D}\)-bundle is a \(V\)-framed object \(M\) of \(\mathcal{P}\) such that

1. \(H^0(M)\) is a torsion-free object of \(\mathcal{Coh}(\mathbb{P}_D)\), and
2. the \(k\)th term in the grading \(\omega(H^0(M))_k\) is a locally free \(\mathcal{O}_X\)-module of rank \((k + 1)\text{rk}(V)\) for all \(k \geq -1\).

The second condition is an open condition on perverse \(\mathcal{D}\)-bundles. If \(\mathcal{D}\) is commutative, this condition just means that the cohomology sheaf \(H^0(M)\) is isomorphic to \(\mathcal{O}_{\mathbb{P}_D}^{rk(V)}\) on the generic fiber of our \(\mathbb{P}^1\)-bundle over \(X\)—in other words, \(H^0(M)\) has “trivial generic splitting type.” This condition is important when studying \(M\) using the Beilinson transform, but it is also worth noting that it is a good condition that appears “in nature”: that is, it agrees with the definition in [BN1] that appears in the study of the KP hierarchy. Since we will not need this in the rest of the paper, we will not give the definition of [BN1]—we only state the following without proof:

Proposition 2.12. Suppose that \(\mathcal{D} = \mathcal{D}_X(L^{\otimes c})\) is a sheaf of twisted differential operators. Then the moduli stack of \(V\)-framed perverse \(\mathcal{D}\)-bundles is isomorphic to the moduli stack of \(V\)-framed \(\mathcal{D}\)-bundles in the sense of [BN1], Definition 3.2.

We will need the following:

Lemma 2.13.

1. If \(N \in \mathcal{Coh}(\mathbb{P}_D)\) is zero-dimensional, then \(h_{\omega N}(k)\) is constant for all \(k \gg 0\).
2. Suppose that \(N \in \mathcal{Coh}(\mathbb{P}_D)\) is zero-dimensional. If \(i_{\Delta}^* N = 0\), then \(Li_{\Delta}^* N = 0\).
3. Suppose that \(M \in \mathcal{P}\). If \(H^0(M)\) is torsion-free, then \(i_{\Delta}^* H^0(M) = Li_{\Delta}^* H^0(M)\).

In particular, if \(M\) is a \(V\)-framed perverse \(\mathcal{D}\)-bundle, then \(i_{\Delta}^* M = i_{\Delta}^* H^0(M) \cong V\).

Proof. A standard argument using finite generation of \(N\) proves (1).

We use the complex

\[\mathcal{R} : \mathcal{R}(-1) \to \mathcal{R},\]

which is quasi-isomorphic to \(\mathcal{R}/t\mathcal{R}\). Thus, \(i_{\Delta}^* N \cong \pi(\mathcal{R} \otimes \omega N)\). Using (1), it follows that, for all \(k\) sufficiently large, multiplication by \(t\) from \(\omega N_k\) to \(\omega N_{k+1}\) is injective if and only if it is surjective. In particular, the homomorphism \(\omega N(-1) \to \omega N\)
has kernel that is a bounded \( R \)-module if and only if its cokernel is a bounded \( R \)-module. This proves (2).

Note that \( \omega H^0(M) \) is torsion-free. It follows that multiplication by \( t \) is injective on \( \omega H^0(M) \), and using \ref{2.11} to compute \( i^*_\infty H^0(M) \) gives (3).

\[ \square \]

**Lemma 2.14.** Suppose that \( N \in \text{Coh}(P_D) \) is zero-dimensional and \( L i^* N = 0 \). Then (with notation as in Section \ref{2.1}) \( \ell((\omega N)_{R(\mathcal{E})}) = 0 \).

**Proof.** If \( D \) is commutative this is well-known. If \( D \) is a ring of twisted differential operators, then the question reduces to the same question for the ring of differential operators \( D_X \). But \( D_X \) has no zero-dimensional modules. \( \square \)

A perverse \( D \)-bundle \( M \) has a local numerical invariant called the (local) second Chern class \( c_2(M) \), defined as follows. Since \( \omega H^0(M) \) is torsion-free, the \( V \)-framing determines an injective homomorphism

\[ \omega H^0(M)/t\omega H^0(M) \to R/tR \otimes V \cong \text{Sym}(T_X) \otimes V. \]

The cokernel of this homomorphism has finite length \( c \) by part (2) of Definition \ref{2.11} Similarly, \( \omega H^1(M)_k \) has finite length as an \( O_X \)-module, which is constant for \( k \gg 0 \); we let \( c' \) denote this length for \( k \gg 0 \).

**Definition 2.15.** With notation as above, \( c_2(M) = c + c' \).

In the commutative case, this definition reproduces the “local contribution to the second Chern class of \( M \).” For example, suppose \( M \) is given by a complex \( O_{\mathbb{P}D} \to Q \), where \( Q \) is a torsion sheaf of length \( n \) on the commutative \( \mathbb{P}^1 \)-bundle \( \mathbb{P}_D \). Then \( c_2(M) = n \) regardless of the map in the complex. In general, such a “local \( c_2 \)”—which measures the failure of \( H^\bullet(M) \) to be locally free—exists, regardless of whether \( X \) is projective (hence our use of the word “local”).

3. Resolution of the Diagonal and Beilinson Transform

We will next develop the analog, for our noncommutative \( \mathbb{P}^1 \)-bundles, of the “fiberwise Beilinson transform.” Although this follows the standard method, it does not seem to appear in the literature in the form we need.

We also explain the main tool for computing the Beilinson transform, namely, an analog of Čech cohomology. More precisely, we will want to compute direct images from the \( \mathbb{P}^1 \)-bundle \( \mathbb{P}_D \) to \( X \), which we carry out using Čech cohomology: essentially, this amounts to covering each \( \mathbb{P}^1 \) by its cover consisting of the affine line (which corresponds to the ring \( D \)) and the “formal neighborhood of the point at infinity” (which is captured using the microlocalization \( \mathcal{E} \) of \( D \)). The Čech cohomology is easy to calculate in some examples (see Corollary \ref{3.15}), which will allow us in Section \ref{4} to explicitly compute the Beilinson transform of a perverse bundle.

3.1. Resolution of the Diagonal. Fix \( X \), \( \mathcal{D}^1 \), and \( R \) as in Section \ref{2.1} Let \( \Delta \) denote the diagonal bigraded \( R \)-bimodule, which is given by \( \Delta_{i,j} = R^{i+j} \) when \( i, j \geq 0 \) and \( \Delta_{i,j} = 0 \) otherwise. There is also a larger bigraded bimodule \( \tilde{\Delta} \) given by \( \tilde{\Delta}_{i,j} = R^{i+j} \) for all \( i, j \).

**Lemma 3.1.** For any object \( M \) of \( \text{Gr} R \), the images of the left \( R \)-modules

\[ \pi(\Delta \otimes_R M) \quad \text{and} \quad \pi(\tilde{\Delta} \otimes_R M) \]

are equal in \( \mathcal{Qcoh}(P_D) \).
Proof. The quotient module $\tilde{\Delta}/\Delta$ is negligible as both a left and a right $\mathcal{R}$-module.

Suppose that $M_{\bullet, \bullet}$ is a bigraded sheaf. We will call $M_{\bullet, \bullet}$ a bigraded left $\mathcal{R}$-module if, for each $k$, $M_{\bullet, k}$ comes equipped with a structure of graded left $\mathcal{R}$-module.

**Definition 3.2.** Given a bigraded left $\mathcal{R}$-module $M_{\bullet, \bullet}$, we write $(p_1)_\ast M = M_{\bullet, 0}$, which is a singly-graded left $\mathcal{R}$-module.

**Lemma 3.3.** The functor $F : \text{Gr} \mathcal{R} \to \text{Gr} \mathcal{R}$ defined by
$$F(M) = (p_1)_\ast (\tilde{\Delta} \otimes_{\mathcal{R}} M) = (\tilde{\Delta} \otimes_{\mathcal{R}} M)_{\bullet, 0}$$

is isomorphic to the identity functor.

**Proof.** This is immediate from the identity $\tilde{\Delta}_i, \bullet = R(i)$ of graded right $\mathcal{R}$-modules.

There is an exact sequence of $\mathcal{R}$-bimodules on $X$:
$$\mathcal{R}(-1) \otimes_{\mathcal{O}} D^1 \otimes_{\mathcal{O}} \mathcal{R}(-1) \overset{\alpha}{\to} \mathcal{R} \otimes_{\mathcal{O}} \mathcal{R} \overset{m}{\to} \Delta \to 0.$$  

Here $m$ is the usual multiplication map and $\alpha = \alpha_1 \otimes t - t \otimes \alpha_2$ is the difference of the two maps given by
$$\alpha_1 : \mathcal{R}(-1) \otimes D^1 \to \mathcal{R}, \quad \alpha_2 : D^1 \otimes \mathcal{R}(-1) \to \mathcal{R}$$
defined by:
$$\alpha_1(D_1 \otimes Z) = D_1 Z, \quad \alpha_2(Z \otimes D_2) = Z D_2.$$  

The kernel of $\alpha$ is easily checked to be the image of $\mathcal{R}(-1) \otimes \mathcal{O} \otimes \mathcal{R}(-1)$ under the natural inclusion, and so we obtain:

**Lemma 3.4.** The complexes of $\mathcal{R}$-bimodules
$$\delta' = \left[ \mathcal{R}(-1) \otimes \mathcal{O} D^1 \otimes_{\mathcal{O}} \mathcal{R}(-1) \overset{\alpha}{\to} \mathcal{R} \otimes_{\mathcal{O}} \mathcal{R} \right]$$
and
$$\delta = \left[ \mathcal{R}(-1) \otimes T_X \otimes \mathcal{R}(-1) \overset{\pi}{\to} \mathcal{R} \otimes \mathcal{R} \right]$$
are quasiisomorphic to $\Delta$.

It is important to note that, although $\alpha$ is defined as the difference of two maps induced from $\mathcal{O}$-module maps $\alpha_1$ and $\alpha_2$, there is, in general, no such description of $\pi$.

**3.2. Beilinson Transform.** For any complex of graded $\mathcal{R}$-modules $P_{\bullet}$, the double complex $\delta \otimes_{\mathcal{R}} P_{\bullet}$ is a double complex of bigraded left $\mathcal{R}$-modules, and we may form
$$B(P_{\bullet}) = (p_1)_\ast (\delta \otimes_{\mathcal{R}} P_{\bullet}) \overset{\text{def}}{=} \text{Tot} ((\delta \otimes_{\mathcal{R}} P_{\bullet})_{\bullet, 0});$$
here $\text{Tot}$ denotes the total complex. We call $B(P_{\bullet})$ the *Beilinson transform* of $P_{\bullet}$. Similarly we may replace $\delta$ by $\delta'$ in (3.3) and obtain a functor denoted by $B'$, also called a *Beilinson transform*.

**Lemma 3.5.** The Beilinson transforms $B$ and $B'$ are exact functors.

**Proof.** Since $\delta$ and $\delta'$ are complexes of projective right $\mathcal{R}$-modules, $B$ and $B'$ are composites of two exact functors $\delta \otimes_{\mathcal{R}} -$ (respectively $\delta' \otimes_{\mathcal{R}} -$) and $(p_1)_\ast$.  

□
Proposition 3.6. For any complex $P_\bullet$ of quasicoherent graded $\mathcal{R}$-modules, there are natural morphisms of complexes

\[(3.4)\] $\mathbb{B}'(P_\bullet) \rightarrow \mathbb{B}(P_\bullet) \rightarrow P_\bullet.$

If $P_\bullet$ is a complex of flat $\mathcal{R}$-modules, then the cones of (3.4) have irrelevant (i.e. locally bounded) cohomologies.

Proof. There are natural maps

\[(3.5)\] $\delta_\mathcal{R}^\prime P_\bullet \rightarrow \delta_\mathcal{R} P_\bullet \rightarrow \Delta_\mathcal{R} P_\bullet.$

Suppose that $P_\bullet$ is a complex of flat $\mathcal{R}$-modules; then the maps (3.5) are quasiisomorphisms by Lemma 3.4, as are the natural maps

$$(p_1)_\ast(\delta_\mathcal{R} P_\bullet) \rightarrow (p_1)_\ast(\Delta_\mathcal{R} P_\bullet).$$

Now, the cone of the natural map

\[(3.6)\] $$(p_1)_\ast(\Delta_\mathcal{R} P_\bullet) \rightarrow (p_1)_\ast(\Delta_\mathcal{R} P_\bullet)$$

is naturally identified with $(p_1)_\ast(\Delta/\Delta \otimes P_\bullet)$ which, by Lemma 3.1, has irrelevant cohomologies. \qed

If $M$ is an object of $D_{dg}(\mathbb{P}_D)$, the Beilinson transform of $M$ is defined to be $\pi(\mathbb{B}(R\omega(M)))$, respectively $\pi(\mathbb{B}'(R\omega(M)))$ (here $R\omega$ denotes the total right derived functor of $\omega$).

Lemma 3.7. Suppose that $M \rightarrow M'$ is a morphism of complexes in $\text{Gr} \mathcal{R}$ whose cone has irrelevant cohomologies. Then the natural morphisms $\pi\mathbb{B}(M) \rightarrow \pi\mathbb{B}(M')$, $\pi\mathbb{B}'(M) \rightarrow \pi\mathbb{B}'(M')$ are isomorphisms in $D_{dg}(\mathbb{P}_D)$.

Proof. It suffices to check that $\pi\mathbb{B}(N) = 0 = \pi\mathbb{B}'(N)$ when $N$ is a module with irrelevant cohomologies. Resolving $N$ by locally free $\mathcal{R}$-modules and using Lemma 3.5, this follows from the second part of Proposition 3.6. \qed

Theorem 3.8. The Beilinson transforms $\mathbb{B}$ and $\mathbb{B}'$ are isomorphic to the identity functor on $D_{dg}(\mathbb{P}_D)$.

Proof. We give the proof for $\mathbb{B}$, the proof for $\mathbb{B}'$ being identical. By Proposition 3.6, there is a natural morphism

$$\pi((p_1)_\ast(\delta \otimes R\omega(P_\bullet))) \rightarrow \pi \circ R\omega(P_\bullet) = P_\bullet.$$

If $P_\bullet$ is an object of $\mathcal{Qcoh}(\mathbb{P}_D)$ of the form $\pi\mathcal{R}(k)$, then the cone of the adjunction $\mathcal{R}(k) \rightarrow R\omega \circ \pi\mathcal{R}(k)$ has irrelevant (i.e. locally bounded) cohomologies [AZ1, Proposition 7.2]. Hence, by Lemma 3.7, we have an isomorphism $\pi(\mathbb{B}(\mathcal{R}(k))) \rightarrow \mathbb{B}(P_\bullet)$ in $D_{dg}(\mathbb{P}_D)$. Now, by Proposition 3.6, we have an isomorphism $\pi\mathbb{B}(\mathcal{R}(k)) \rightarrow \pi\mathcal{R}(k) = P_\bullet$. It follows that the natural map $\mathbb{B}(P_\bullet) \rightarrow P_\bullet$ is an isomorphism in this case. Since every object of $D_{dg}(\mathbb{P}_D)$ is isomorphic to a complex of direct sums of objects $\pi\mathcal{R}(k)$ as above, the theorem follows by Lemma 3.3. \qed

Remark 3.9. Everything in this section and the previous one seems to work without complications for an arbitrary noncommutative $\mathbb{P}^1$-bundle in the sense of Van den Bergh [VdB2]. This is interesting to work out in the case of difference operators, which we plan to carry out in [BN3].
3.3. Čech Resolution. In this section, we define an analog of the Čech resolution for \( \mathcal{Q}_{\text{coh}}(\mathbb{P}_D) \). We will use this to compute Beilinson transforms.

We begin with some general observations. For any filtered ring \( S \) and its associated Rees ring \( \mathcal{R}(S) \), one has two functors between the categories of filtered \( S \)-modules and graded \( \mathcal{R}(S) \)-modules. The first functor takes a filtered \( S \)-module \( M \) with filtration \( \{M_k\} \) to the graded \( \mathcal{R}(S) \)-module \( \oplus_k M_k \). In the other direction, given a graded \( \mathcal{R}(S) \)-module \( N \), one may invert \( t \) and take the degree zero term, \( f(N) = \ell(N)_0 \). This is naturally a module over \( \mathcal{R}(S)[t^{-1}]_0 = S \); moreover, \( f(N) \) has a filtration given by the images of \( N_k t^{-k} \) in \( f(N) \). This filtration makes \( f(N) \) into a filtered \( S \)-module. These functors are studied in [LvO].

Suppose now that \( M \) is a quasicoherent graded \( \mathcal{R} \)-module. Recall that \( \ell(M) \) means the localization of \( M \) given by inverting \( t \), and \( M_{\mathcal{R}(\mathcal{E})} = \mathcal{R}(\mathcal{E}) \otimes_{\mathcal{R}([D])} M \), the microlocalization.

**Definition 3.10.** The Čech complex of \( M \) is the complex
\[
C(M) = \left[ \ell(M) \oplus M_{\mathcal{R}(\mathcal{E})} \xrightarrow{\delta_M} \ell(M_{\mathcal{R}(\mathcal{E})}) \right]
\]
of \( \mathcal{R} \)-modules (implicitly, we compose localization or microlocalization with the forgetful functor back to \( \mathcal{R} \)). Here the map \( \delta_M \) is the difference of the two natural maps \( \ell(M) \to \ell(M_{\mathcal{R}(\mathcal{E})}) \) and \( M_{\mathcal{R}(\mathcal{E})} \to \ell(M_{\mathcal{R}(\mathcal{E})}) \) determined by the adjunctions of Lemma 2.3.

See the proof of Corollary 3.15 below for the description of this complex in an example.

As described, we cannot simply apply the functor \( \pi \) to get a Čech complex \( \pi C(M) \) of objects of \( \mathcal{Q}_{\text{coh}}(\mathbb{P}_D) \): indeed, the “microlocal” terms in \( C(M) \) are typically not quasicoherent over \( \mathcal{O}_X \). To remedy this, we may replace \( C(M) \) with the complex
\[
[\ell(M) \to \ell(M_{\mathcal{R}(\mathcal{E})})/M_{\mathcal{R}(\mathcal{E})}]
\]
which does consist of objects of \( \text{Gr} \ \mathcal{R} \). Since the kernel of \( M_{\mathcal{R}(\mathcal{E})} \to \ell(M_{\mathcal{R}(\mathcal{E})}) \) is a locally bounded module, the images in \( \mathcal{Q}_{\text{coh}}(\mathbb{P}_D) \) of these complexes are quasiisomorphic functorially in \( M \). Hence, we will usually ignore the distinction between (the results of applying \( \pi \) to) \( C(M) \) and (3.3).

**Remark 3.11.** As we alluded to above, when \( D \) is commutative, \( \ell(M) \) corresponds to the restriction of the quasicoherent sheaf (corresponding to) \( M \) on \( \mathbb{P}_D \) to \( \text{Spec}(D) \). Moreover, \( M_{\mathcal{R}(\mathcal{E})} \) corresponds to the restriction of \( M \) to the formal neighborhood of the “curve at infinity” \( X_\infty \subset \mathbb{P}_D \), and \( \ell(M_{\mathcal{R}(\mathcal{E})}) \) corresponds to the restriction of \( M \) to the “punctured formal neighborhood” of \( X_\infty \), i.e. the formal neighborhood minus \( X_\infty \) itself. Thus, \( C(M) \) is exactly the Čech complex corresponding to a cover of the \( \mathbb{P}^1 \)-bundle, fiber-by-fiber, by affine lines and formal disks around the points at infinity in each fiber.

The Čech complex comes equipped with a natural morphism \( M \to C(M) \) given by the adjunction \( M \to \ell(M) \) minus the adjunction \( M \to M_{\mathcal{R}(\mathcal{E})} \).

**Proposition 3.12.**
1. The Čech complex functor is exact.
2. The Čech complex functor descends to an exact endofunctor of \( \text{Qgr} \ \mathcal{R} \).
3. \( C(M) \) is a complex of acyclic objects for the functor \( \omega : \text{Qgr} \ \mathcal{R} \to \text{Gr} \ \mathcal{R} \).
(4) The natural morphism $M \to C(M)$ is a quasiisomorphism of complexes in $\text{Qgr } \mathcal{R}$.

Proof: (1) follows from Lemma 2.3. (2) follows from Corollaries 4.3.11 and 4.3.12 of [P], once one observes that inverting $t$ and microlocalization both kill locally bounded modules.

For (3), we first restrict attention to an affine open subset $U$ of $X$ and work as in Remark 2.7: that is, we work with the ring $\mathcal{R}(U)$ rather than the sheaf of rings $\mathcal{R}$. In this case the Čech complex as defined in (3.7) is a complex in $\text{Qgr } \mathcal{R}(U)$. We now make several applications (for the functors $\ell$, $(\cdot)_{\mathcal{R}(\mathcal{E})}$, and $\ell(\cdot)_{\mathcal{R}(\mathcal{E})}$) of the following general fact.

**Lemma 3.13.** Let $\mathcal{C}, \mathcal{D}$ be abelian categories and $\mathcal{T} \subset \mathcal{C}$ a dense subcategory. Let $\ell: \mathcal{C} \to \mathcal{D}$ be an exact functor with exact right adjoint $f: \mathcal{D} \to \mathcal{C}$ so that $\ell(X) = 0$ for all $X \in \text{ob}(\mathcal{T})$. Let $(\pi: \mathcal{C} \leftrightarrow \mathcal{C}/\mathcal{T}: \omega)$ denote the “standard” adjoint pair of functors. Let $\mathcal{T}: \mathcal{C}/\mathcal{T} \to \mathcal{D}$ be the functor determined by $\mathcal{T} \circ \pi = \ell$ and $\mathcal{T}$ its right adjoint. Then $\mathcal{T}$ is exact and $R\omega \circ \mathcal{T} = \omega \circ \mathcal{T}$.

It follows that (3.7) consists of acyclic objects for $\omega$, and consequently that (3.8) also consists of acyclic objects. But (3.8) is now the complex of sections over $U$ of the (sheafified) Čech complex, and (3) follows.

To prove (4) it suffices, by (2), to prove (4) for objects $\pi \mathcal{R}(k)$, for which see (3.9) below.

**Corollary 3.14.** If $P_\bullet \in D_{dg}(\mathcal{P}_D)$, then $C(P_\bullet) \simeq R\omega(P_\bullet)$.

**Corollary 3.15** (Calculations of Čech Cohomology).

(1) We have

$$(3.9) \quad H^\bullet((p_1)_*, R\omega(\pi \mathcal{R}(n))) = \begin{cases} \mathcal{D}^n & \text{if } n \geq -1, \\
(\mathcal{E}^{-1}/\mathcal{E}^n)[-1] & \text{if } n \leq -2. 
\end{cases}$$

In particular, $(p_1)_* R\omega(\pi \mathcal{R}(-2)) \cong \Omega^1_X[-1]$.

(2) For objects $A, B \in D_{dg, qcoh}(X)$ and $\ell \geq k$, we have

$$(3.10) \quad R\text{Hom}_{\text{Qgr}} \pi(\pi \mathcal{R}(k) \otimes A, \pi \mathcal{R}(\ell) \otimes B) = R\text{Hom}_X(A, \mathcal{D}^{\ell-k} \otimes B).$$

Proof. Assertion (1) follows from a computation of the Čech cohomology of $\pi \mathcal{R}(n)$. Indeed, the Čech complex of $\pi \mathcal{R}(n)$ is just

$$\mathcal{D}[t](n) \oplus \mathcal{R}(\mathcal{E})(n) \to \mathcal{E}[t](n).$$

Applying $(p_1)_*$ to this complex (i.e. taking the part in graded degree 0) gives

$$(3.11) \quad \mathcal{D} \oplus \mathcal{E}^n \to \mathcal{E},$$

where $\mathcal{E}^n$ is the $n$th term in the filtration of $\mathcal{E}$. If $n \geq -1$ then (3.11) is surjective, with kernel $\mathcal{D} \cap \mathcal{E}^n = \mathcal{D}^n$. If $n \leq -2$ then (3.11) is injective, with cokernel $\mathcal{E}/(\mathcal{D} + \mathcal{E}^n) \cong \mathcal{E}^{-1}/\mathcal{E}^n$.

Equation (3.10) then follows immediately from (3.9) using the usual “induction-restriction adjunction.”
4. EQUIVALENCE AND ISOMORPHISM

In this section we prove two main consequences of the Beilinson transform of the previous section.

First, we prove the standard consequence of the Beilinson procedure: that the derived category of our noncommutative \( \mathbf{P}^1 \)-bundle, \( D_{dg}(\mathbb{P}_D) \), is quasi-equivalent to a dg category described completely in terms of “linear algebra” or “quiver data,” which we call the dg category \( \text{Kos} \) of Koszul data. Namely, the Beilinson transform shows that \( D_{dg}(\mathbb{P}_D) \) is generated by the analog of the exceptional collection \( \{O(-1), O\} \) and hence may be described via modules over the endomorphism algebra of this collection. In our setting, when everything is done in families over the curve \( X \), this amounts to describing an object of \( D_{dg}(\mathbb{P}_D) \) in terms of a pair of quasicoherent complexes on the curve \( X \) together with the data encoding the lift to the \( \mathbf{P}^1 \)-bundle, i.e. an action of \( \mathbf{D}^1 \) from one complex on \( X \) to the other.

Second, we describe explicitly (Theorem 4.6) which Koszul data (objects of \( \text{Kos} \)) correspond to perverse bundles in \( D_{dg}(\mathbb{P}_D) \). This amounts to doing a Čech calculation starting from a perverse bundle, and, conversely, computing the cohomologies of an object of \( D_{dg}(\mathbb{P}_D) \) starting from an object of \( \text{Kos} \). As we explain below, once one has carried through these calculations at the level of objects, the framework of dg categories gives the equivalence of the moduli essentially “for free.”

All tensor products in this section are taken over \( \mathcal{O}_X \).

4.1. DG CATEGORY OF KOSZUL DATA. Let \( \mathcal{P} \) denote the sheaf of rings on \( X \) consisting of \( 2 \times 2 \) upper triangular matrices whose diagonal coefficients lie in \( \mathcal{O}_X \) and whose upper-left entry lies in \( \mathbf{D}^1 \):

\[
\mathcal{P} = \left\{ \begin{pmatrix} f_1 & D \\ 0 & f_2 \end{pmatrix} \bigg| f_1, f_2 \in \mathcal{O}_X, D \in \mathbf{D}^1 \right\}.
\]

This algebra is the version, for our noncommutative \( \mathbf{P}^1 \) bundle \( \mathbb{P}_D \), of the endomorphism (or self-Ext) algebra of the Beilinson generator \( \mathcal{O}(-1) \oplus \mathcal{O} \) on \( \mathbf{P}^1 \) (see below).

We let \( \text{Kos} \) denote the abelian category consisting of quasicoherent sheaves \( M \) together with a map \( \mathcal{P} \otimes \mathcal{O}_X M \to M \) that defines a \( \mathcal{P} \)-module structure (and whose morphisms are \( \mathcal{P} \)-linear maps). It is immediate that specifying such a module is the same as giving a pair of quasicoherent \( \mathcal{O}_X \)-modules \( M_{-1}, M_0 \) (our choice of labelling will seem more natural in light of Theorem 4.3) together with an \( \mathcal{O}_X \)-linear map \( \mathbf{D}^1 \otimes \mathcal{O}_X M_{-1} \xrightarrow{a} M_0 \), an action map.

Definition 4.1. The dg category of Koszul data is the dg derived category \( \text{Kos} \) of the abelian category \( \text{Kos} \).

Objects of \( \text{Kos} \) are thus given by pairs \( (M_{-1}, M_0) \) of quasicoherent complexes on \( X \) together with an action map \( a : \mathbf{D}^1 \otimes M_{-1} \to M_0 \). Let \( V \in D(X) \) be a coherent complex on \( X \). An object \( (M_{-1}, M_0, a) \) of \( \text{Kos} \) is \( V \)-framed if it comes equipped with a quasi-isomorphism \( \text{Cone}(M_{-1} \xrightarrow{a|_{M_{-1}}} M_0) \simeq V \); here \( a|_{M_{-1}} \) means the restriction of \( a \) to \( M_{-1} \subset \mathbf{D}^1 \otimes M_{-1} \).

4.2. GENERAL EQUIVALENCE THEOREM. Let \( G = \pi \mathcal{R} \oplus \pi \mathcal{R}(1) \) in \( D_{dg}(\mathbb{P}_D) \) (of course, this is the image of an object of \( \text{Coh}(\mathbb{P}_D) \)). It follows from Corollary 3.13 that the sheaf of dg algebras \( \text{Hom}^\bullet_{D_{dg}(\mathbb{P}_D)}(G, G) \) is canonically quasi-isomorphic to
the sheaf of algebras $P$ defined above (that is, concentrated in cohomological degree 0).

Given an object $M$ of $D_{dg}(\mathbb{P}_D)$, we get a complex of (left!) $P$-modules $M$ by setting $M = \text{Hom}^\bullet_{D_{dg}(\mathbb{P}_D)}(G, M)$. It is instructive to apply this procedure to an output of the Beilinson functor $\mathbb{B}$, i.e. to the total complex associated to a double complex

\[ M : \pi R(-1) \otimes T_X \otimes M_{-1} \rightarrow \pi R \otimes M_0 \]  

(that is, $M_{-1}$ and $M_0$ are quasicoherent complexes on $X$). It follows from Corollary 3.15 that:

**Lemma 4.2.** For $M$ as in (4.1),

\[ \text{Hom}^\bullet(\pi R(1), M) \simeq M_{-1} \quad \text{and} \quad \text{Hom}^\bullet(\pi R, M) \simeq M_0. \]

We now have:

**Theorem 4.3.**

1. There is a quasi-equivalence of differential graded categories from $D_{dg}(\mathbb{P}_D)$ to $\text{Kos}$ that takes an object $M$ of $D_{dg}(\mathbb{P}_D)$ to $\text{Hom}^\bullet_{D_{dg}(\mathbb{P}_D)}(G, M)$.
2. Under this quasi-equivalence, if an object $M$ of $D_{dg}(\mathbb{P}_D)$ is identified with a triple $M = (M_{-1}, M_0, a)$ of $\text{Kos}$, then a choice of $V$-framing of $M$ corresponds to a choice of $V$-framing of $M$.

**Proof.** By definition of quasi-equivalence $\text{Ke3}$, it suffices to define a functor of dg categories that induces an equivalence of the homotopy categories (as triangulated categories). The functor described above at the level of objects defines a functor from $D_{dg}(\mathbb{P}_D)$ to $\text{Kos}$ by a standard procedure (see Section 4 of $\text{Ke1}$ or Section 8.7 of $\text{Ke2}$). Moreover, by Theorem 4.3 of $\text{Ke1}$ (see also the theorem in Section 8.7 of $\text{Ke2}$), if $X$ is affine—so that the category $\text{Kos}$ is a (derived) module category for a ring, not just a sheaf of rings—then, to conclude that this functor induces an equivalence of the homotopy categories, it suffices to check that the compact object $G$ is a generator of $D_{dg}(\mathbb{P}_D)$. But this is immediate from Theorem 3.8. Finally, for projective $X$, we obtain a compatible collection of such functors for all open subsets of $X$. By the above discussion, these functors are quasi-equivalences for all affine open subsets of $X$. It then follows from effective descent for dg categories that the functor $\text{Hom}^\bullet(G, -)$ gives a quasi-equivalence over $X$ as well. More precisely, the dg categories $D_{dg}(\mathbb{P}_D)$ and $\text{Kos}$ are homotopy limits of the categories over affine open subsets of $X$—they are obtained by totalizing the cosimplicial dg categories associated to the Čech nerve of an affine cover. (See $\text{BD}$ (Section 7.4) or $\text{HS}$ (Section 21) for descent of dg categories of sheaves.)

We now prove the second part of the theorem. We first note the following. Consider the complex of bigraded $R$-bimodules $\delta$ in Section 3.1. Take the associated graded complex with respect to the left-hand grading. The description of the map $\pi$ in terms of $\alpha_1$ and $\alpha_2$ shows that, after passing to associated graded with respect to the left-hand grading, $\pi$ is identified with $\alpha_1 \otimes t$.

Consider now a double complex of the form (4.1), an output of the functor $\mathbb{B}$; by Lemma 4.2 the corresponding Koszul data are $(M_{-1}, M_0, a)$. Applying $i_*^\infty$ to (4.1) gives

\[ [\pi(\text{Sym} T_X)(-1) \otimes T_X \otimes M_{-1} \rightarrow \pi \text{Sym}(T_X) \otimes M_0]. \]
By the conclusion of the previous paragraph, this map is just the tensor product of the identity map $\pi \text{Sym} T_X(-1) \otimes T_X \to \text{Sym} T_X$ with $a|_{M_{-1}}$. Under the identification of $\text{Qcoh}(X)$ with $\text{Qgr Sym}(T_X)$ (more precisely, of their derived categories), this is then identified with $a|_{M_{-1}}$. Part (2) of the theorem is then immediate from the two definitions of $V$-framing. \hfill \Box

4.3. Calculating in $\text{Kos}$. Let $V$ be a sheaf on $X$. We want to calculate some $V$-framed objects of $\text{Kos}$ that have a particularly simple form: their components $M_{-1}$ are (quasi-isomorphic to) sheaves in cohomological degree 1.

Suppose $M$ is a $V$-framed object of $\text{Kos}$. As we have remarked above, since our sheaf of rings $P$ has two projections onto $\mathcal{O}_X$, $M$ gives two quasi-coherent complexes $M_{-1}$ and $M_0$; more precisely, we get two functors to $D_{dg}(X)$. Suppose that $M_{-1}$ is quasi-isomorphic to a sheaf in cohomological degree 1. Letting $Q = H^1(M_{-1})$, we then get a canonical quasi-isomorphism $M_{-1} \to Q[-1]$. Furthermore, the $V$-framing of $M$—that is, the choice of quasi-isomorphism $\text{Cone}(M_{-1} \to M_0) \simeq V$—yields a choice of quasi-isomorphism $M_0 \to \text{Cone}(V \to Q)$ (with $V$ in cohomological degree 0), i.e. up to quasi-isomorphism $M_0$ corresponds to a choice of morphism $V \overset{i}{\to} Q$. The action map $a : D^1 \otimes M_{-1} \to M_0$ then yields a unique map $a : D^1 \otimes Q[-1] \to \text{Cone}(V \to Q)$ in $D_{dg}(X)$. This map has the property that the composite

$$Q[-1] \to D^1 \otimes Q[-1] \to \text{Cone}(V \to Q)$$

(4.2) equals the “natural” map $Q[-1] \to \text{Cone}(V \to Q)$.

Suppose, for the moment, that $Q$ is a quasi-coherent sheaf on $X$, $V \overset{i}{\to} Q$ is a choice of homomorphism, and $a : D^1 \otimes Q[-1] \to \text{Cone}(V \overset{i}{\to} Q)$ is a choice of map in $D_{dg}(X)$ whose composite $\xrightarrow{\text{(4.2)}}$ equals the natural map $Q[-1] \to \text{Cone}(V \overset{i}{\to} Q)$. We will refer to $(Q, i, a)$ as a $\text{Koszul triple}$ on $X$. We will define the set of morphisms of triples $(Q, i, a) \to (Q', i', a')$ to consist of morphisms $Q \overset{\phi}{\to} Q'$ so that the diagram

$$
\begin{array}{ccc}
D^1 \otimes Q[-1] & \xrightarrow{a} & \text{Cone}(V \overset{i}{\to} Q) \\
\downarrow \scriptstyle{1_{D^1} \otimes \phi} & & \downarrow \scriptstyle{1_V \times \phi} \\
D^1 \otimes Q'[-1] & \xrightarrow{a'} & \text{Cone}(V \overset{i'}{\to} Q)
\end{array}
$$

commutes in $D_{dg}(X)$. This defines a category of triples $(Q, i, a)$. Similarly, we let $\text{Kos}^0(V)$ denote the category of $V$-framed objects $M$ in $\text{Kos}$ such that $M_{-1}$ is quasi-isomorphic to a sheaf in cohomological degree 1; $\text{Homs}$ are morphisms in $\text{Kos}$ that are compatible with the $V$-framing.

**Proposition 4.4.** There is an equivalence of categories between:

1. The category $\text{Kos}^0(V)$.
2. The category of triples $(Q, i, a)$.

**Proof.** The above constructions define a functor from $\text{Kos}^0(V)$ to the category of Koszul triples. It is faithful, since our analysis of $M_{-1}$ and $M_0$ shows that any map of Koszul data $M \to M'$ is determined by the induced map $Q = H^1(M_{-1}) \to H^1(M'_{-1}) = Q'$.

To see that this functor is full and essentially surjective, we do the following. Given $(Q, i, a)$, choose representatives $M_{-1}$ and $M_0$ of $Q[-1]$ and $V \to Q$ in $D_{dg}(X)$,
respectively, for which a lift \( a : D^1 \otimes M_{-1} \to M_0 \) exists (for example, choose a complex of injectives representing \( M_0 \)). Applying the functor to the Koszul data \((M_{-1}, M_0, a)\) returns \((Q, i, a)\)—that is, the functor is essentially surjective. Furthermore, given another triple \((Q', i', a')\), we may choose complexes of injectives \( M'_{-1} \) and \( M'_0 \) quasi-isomorphic to \( Q' \) and \( V \to Q' \), so that \( a' \) lifts to an action map \( D^1 \otimes M'_{-1} \xrightarrow{a'} M'_0 \) and \((M'_{-1}, M'_0, a')\) is mapped to \((Q', i', a')\). Then any map \( Q \to Q' \) lifts to a map \( M_{-1} \xrightarrow{\phi} M'_{-1} \). It then suffices to choose a map \( M_0 \to M'_0 \) compatible with \( \phi \) and the given quasi-isomorphisms to \( V \), but the existence of such a map is guaranteed by injectivity of \( M'_0 \) using an exact sequence argument. \( \square \)

We will use this description in Theorem 4.6 below.

4.4. Moduli of Perverse Bundles. Fix a vector bundle \( V \) on \( X \).

**Definition 4.5.** Let \( PS(X, V) \) denote the moduli stack of pairs \((Q, i)\) consisting of a coherent torsion sheaf \( Q \) on \( X \) and a homomorphism \( i : V \to Q \); we call the component parametrizing pairs \((Q, i)\) with \( Q \) of length \( n \) the \( n \)th perverse symmetric power of \( X \).

In the case \( D^1 = O_X \oplus T_X \) (commutative), we let \( PB(X, V) \) denote the moduli stack of \( V \)-framed perverse \( D \)-bundles. In the case when \( D^1 = D^1_X \) consists of first-order differential operators, we let \( CM(X, V) \) denote the moduli stack of \( V \)-framed perverse \( D \)-bundles.

We will now describe the moduli stacks \( PB(X, V) \) and \( CM(X, V) \) in terms of stacks that “live over” \( PS(X, V) \).

**Theorem 4.6.** The moduli stacks for the following data are isomorphic:

1. \( V \)-framed perverse \( D \)-bundles \( \mathcal{M} \) with second Chern class \( c_2 \).

2. triples \((Q, i, a)\) where \( Q \) is a torsion sheaf on \( X \) of length \( c_2 \), \( i : V \to Q \) is a homomorphism of \( O \)-modules, and \( a : D^1 \otimes Q[-1] \to \text{Cone}(V \xrightarrow{i} Q) \) is a morphism in the dg derived category of \( O \)-modules such that the induced morphism \( O \otimes Q[-1] \to \text{Cone}(V \xrightarrow{i} Q) \) is the natural one.

**Remark 4.7.** It is instructive to consider what the theorem says in case \( \mathcal{R} \) is commutative and \( \mathcal{M} \) is a rank 1 torsion-free sheaf. Let \( X_\infty \) denote the “divisor at infinity” in \( S = \text{Proj}(\mathcal{R}) \) and \( i_\infty : X_\infty \to S \) the inclusion. Let \( p : S \to X \) denote the projection. Note that \( \text{Qgr}(\mathcal{R}) \simeq \text{Qcoh}(S) \).

By condition (2) of Definition 2.11, \( \mathcal{M} \) comes equipped with an injective homomorphism \( \mathcal{M} \hookrightarrow p^* V \). We let \( Q \) denote the cokernel; this gives an exact sequence

\[
\begin{align*}
0 & \to \mathcal{M} \to p^* V \to Q \to 0.
\end{align*}
\]

We have \( M_0 = \mathbb{R}p_* (\mathcal{M}) \) and \( M_{-1} = \mathbb{R}p_* (\mathcal{M}(-X_\infty)) \). We also set \( Q = p_* Q \); this is a torsion sheaf of length \( c_2(\mathcal{M}) \). Using the sequence (4.3), one finds that \( M_0 \simeq [V \xrightarrow{i} p_* Q] \) and \( M_{-1} \simeq p_* Q(-X_\infty) \equiv Q \).
Proof of Theorem 4.6. In light of Proposition 4.3 it suffices to check that, under the correspondence of Theorem 4.3 above, the perverse $D$-bundles correspond to Koszul data $(M_{-1}, M_0, a)$ in which $M_{-1} = (p_1)_* R\omega(M(-1))$ is quasi-isomorphic to $Q[-1]$ for $Q$ a torsion sheaf of length $c_2$.

The strategy of the proof, then, is simple: we start with a perverse bundle $M$ and compute
\[
\text{Hom}^\bullet(G, \mathcal{M}) = M_{-1} \oplus M_0 \simeq (p_1)_* R\omega(\mathcal{M}) \oplus (p_1)_* R\omega(\mathcal{M}(-1))
\]
and show that it has the desired form. Then, going the other way, we start with a triple $(Q, i, a)$—equivalently by Proposition 4.4—with framed Koszul data—and compute the corresponding object of $D_{dg}(\mathbb{P}_D)$.

Correspondence for $C$-points. We first give the proof at the level of $C$-valued points. Later we will explain that this is already enough to give the equivalence in families, i.e. an isomorphism of stacks.

Suppose first that $M$ is a $V$-framed perverse $D$-bundle. In order to check that the corresponding triple $(M_{-1}, M_0, a)$ of Koszul data has the desired property, it suffices to compute the “derived direct image” $(p_1)_* R\omega(\mathcal{M})$ and prove that it is a torsion sheaf (in cohomological degree 1) of length $c_2$. To carry out this calculation, we use the exact triangle
\[H^1(\mathcal{M})(-1)[-1] \to \mathcal{M}(-1) \to H^0(\mathcal{M})(-1) \] in the triangulated derived category. By Lemma 2.13 the natural map
\[V \simeq i^*_\infty \mathcal{M}(-1) \to Li^*_\infty H^0(\mathcal{M})(-1)\]
is a quasi-isomorphism, and it follows that $Li^*_\infty H^1(\mathcal{M})(-1) = 0$: in other words, “the zero-dimensional object $H^1(\mathcal{M})(-1)$ is supported away from $X_\infty$.”

Write $H = \omega H^1(\mathcal{M})(-1)$. By Lemma 2.13 and the conclusion of the previous paragraph, $\ell(\mathcal{H}_X) = 0$. Thus, using Formula (3.5) for the Čech complex $C(H)$, $C(H) = (p_1)_* C(L)$ is given by $C(H) \simeq H[t^{-1}]$ and $(p_1)_* C(H)$ is a torsion coherent sheaf on $X$ of length $c'$ (notation as in Definition 2.15). For $L = H^0(\mathcal{M})(-1)$, the argument of Proposition 5.8 of [BN1] (more specifically, the exact sequence (5.2) applies here to prove that $H^0((p_1)_* C(L)) = 0$ and $H^1((p_1)_* C(L))$ is a coherent $O_X$-torsion sheaf of length $c$ (notation as in Definition 2.15).

Taking account of the cohomological degrees of the “direct images” of the left-and right-hand terms in (4.4), it is now immediate from that $(p_1)_* R\omega(\mathcal{M})(-1)[1]$ is concentrated in a single cohomological degree. It follows that $(p_1)_* R\omega(\mathcal{M})(-1)[1]$ is a torsion $O_X$-module of length $c + c' = c_2$, as desired. Summarizing, we have proven that a $V$-framed perverse $D$-bundle $M$ gives a triple of Koszul data as claimed in the statement of the theorem.

We will now prove the converse: Koszul data that reduce, via Proposition 4.4 to a triple $(Q, i, a)$ as in part (2) of the theorem correspond, under Theorem 4.3 to a perverse bundle with the prescribed $c_2$.

Suppose we are given Koszul data $(M_{-1}, M_0, a)$ that correspond to a triple $(Q, i, a)$ as in part (2) of the present theorem. We set
\[\mathcal{M} = \text{Tot} \left[ \pi \mathcal{R}(-1) \otimes T_X \otimes M_{-1} \to \pi \mathcal{R} \otimes M_0 \right],\]
the object of $D_{dg}(\mathbb{P}_D)$ corresponding to $(M_{-1}, M_0, a)$ (see Lemma 4.2 and note that $\pi \mathcal{R} \otimes M_0$ lies in cohomological degree 0, not 1). To compute whether $\mathcal{M}$ is
a perverse bundle, it suffices to compute in the triangulated category—that is, we may compute cohomologies of $\mathcal{M}$ using the quasi-isomorphic object

$$\overline{\mathcal{M}} = \text{Tot} \left[ \pi\mathcal{R}(-1) \otimes T_X \otimes Q[-1] \rightarrow \pi\mathcal{R} \otimes \text{Cone}(V \rightarrow Q) \right]$$

in the triangulated derived category (again, note the normalization, that the right-hand term $\pi\mathcal{R} \otimes \text{Cone}(V \rightarrow Q)$ of the double complex lies in “horizontal cohomological degree 0”). In particular, one sees from this description of $\overline{\mathcal{M}}$ that $H^k(\mathcal{M}) = 0$ for $k \neq 0, 1$. Furthermore, over $U = X \setminus \text{supp}(Q)$, (4.6) immediately reduces to

$$\overline{\mathcal{M}}|_U = V \otimes \pi\mathcal{R}|_U;$$

in particular, this implies the rank condition of part (2) of Definition 2.11—the “locally free” part of the condition is immediate provided $H^0(\mathcal{M})$ is a torsion-free object of $\mathcal{Q}\text{coh}(\mathbb{P}_D)$, which we will prove below.

We next prove that $H^1(\mathcal{M})$ is zero-dimensional. By (4.7), $\omega H^1(\mathcal{M})$ is supported over $\text{supp}(Q) \subset X$. Moreover, applying $i_*^\infty$ to (4.6), we find that $i_*^\infty H^1(\mathcal{M})$ is the cokernel of a map

$$\pi(\text{Sym } T_X \otimes V) \oplus ((\text{Sym } T_X (-1)) \otimes T_X \otimes Q) \rightarrow \pi \text{ Sym } T_X \otimes Q.$$

By an argument similar to the proof of part (2) of Theorem 4.3 this map is surjective; in particular, $i_*^\infty H^1(\mathcal{M}) = 0$. It follows that $\omega H^1(\mathcal{M})$ is $\mathcal{O}$-coherent. Since $H^1(\mathcal{M})$ is also $\mathcal{O}_X$-torsion (supported on $\text{supp}(Q)$), it is zero-dimensional.

By the previous paragraph and Lemma 2.13 Li $i_*^\infty H^1(\mathcal{M}) = 0$, and hence, since (4.8) comes equipped with a quasi-isomorphism to $\text{Sym } T_X \otimes V$, we get a quasi-isomorphism of $i_*^\infty \mathcal{M}$ with $V$. Hence $\mathcal{M}$ is $V$-framed.

To see that $\mathcal{M}$ is a perverse bundle, it remains only to prove that $H^0(\mathcal{M})$ is torsion-free. The description (4.6) gives us an exact triangle

$$\pi\mathcal{R} \otimes \text{Cone}(V \rightarrow Q) \rightarrow \overline{\mathcal{M}} \rightarrow \pi\mathcal{R}(-1) \otimes T_X \otimes Q \rightarrow [1]$$

(the lack of shifts may look unexpected, but results from the shifts implicit in our description of $\mathcal{M}$ via (4.6)). The associated long exact sequence takes the form

$$0 \rightarrow H^0((\pi\mathcal{R} \otimes \text{Cone}(V \rightarrow Q))) \rightarrow H^0(\mathcal{M}) \rightarrow H^0(\pi\mathcal{R}(-1) \otimes T_X \otimes Q).$$

Applying $\omega$, this remains left exact. Moreover, the left-hand term $\omega H^0(\pi\mathcal{R} \otimes \text{Cone}(V \rightarrow Q))$ is a subobject of $\mathcal{R} \otimes V$, hence is torsion-free. Consequently, if $\omega H^0(\mathcal{M})$ is not torsion-free, then its torsion submodule $\tau$ maps injectively to a submodule of

$$\omega H^0(\pi\mathcal{R}(-1) \otimes T_X \otimes Q) = \mathcal{R}(-1) \otimes T_X \otimes Q;$$

in particular, the torsion submodule is a direct summand of $\omega H^0(\mathcal{M})$ and is isomorphic to a submodule of $\mathcal{R}(-1) \otimes T_X \otimes Q$. Now $i_*^\infty H^0(\mathcal{M})$ is torsion-free, so $i_*^\infty \pi(\tau) = 0$. It follows that $t \cdot \tau_k = \tau_{k+1}$ for $k \gg 0$. But it is clear that no nonzero submodule of $\mathcal{R} \otimes T_X \otimes Q$ has this property. This proves that $H^0(\mathcal{M})$ is torsion-free, thus completing the proof that $\mathcal{M}$ is a $V$-framed perverse $\mathcal{D}$-bundle.

We thus have the desired equivalence at the level of $\mathbb{C}$-valued points of the stack.

Correspondence in families. This is essentially a formal consequence of what we have already proven. More precisely, following [Li] Definition 2.1.8 and Proposition 2.1.9 (or, more generally, [TV]) there is an intrinsic notion of $S$-object in a dg category (where $S$ is a locally noetherian scheme). A quasi-equivalence of dg categories induces an equivalence of the associated categories fibered in groupoids.
over schemes. The only additional information that one would like is that, if one has a “classical” notion of flat family, the two notions coincide.

For families $M$ of $V$-framed perverse $D$-bundles for which $H^0(M_s) = 0$ for every geometric point $s \in S$ this is straightforward (note, for example, that this applies to every family when $D$ is a TDO algebra). Such a family certainly satisfies the condition $\text{Ext}^i(M_s, M_s) = 0$ for $s \in S$ and $i < 0$ that appears in the definition of a universally gluable family. Conversely, suppose $M$ is a universally gluable $S$-object of $D_{dg}(P_D)$ all of whose geometric fibers $M_s$ are $(V$-framed) perverse $D$-bundles and such that $H^i(M_s) = 0$ for $i \neq 0$ (note that here $M_s$ means derived restriction). It follows by [Br1, Lemma 4.3] that $H^i(M) = 0$ for $i \neq 0$ and that $H^0(M)$ is $S$-flat.

5. Calogero-Moser Spaces as Twisted Cotangent Bundles

In this section we identify precisely the moduli stacks of perverse bundles $PB$ on $T^*X$ and $D$-bundles $CM$ and the relation between them. Recall (Definition 4.5) that $\text{PS}(X,V)$ denotes the moduli stack of pairs $(Q,i)$ consisting of a coherent torsion sheaf $Q$ on $X$ and a homomorphism $i: V \to Q$. For fixed $(Q,i)$ we may now consider its possible extensions to data $(Q,i,a)$ which by Theorem 4.6 describe either perverse bundles or $D$-bundles. In the first case, $a$ is completely determined by a map $a: T_X \otimes Q[-1] \to \text{Cone}(V \to Q)$, while in the latter case $a$ is a map $D^1 \otimes Q[-1] \to \text{Cone}(V \to Q)$ with fixed restriction to $O \otimes Q[-1]$. It is clear that the latter data form a pseudo-torsor over the former: in other words, there is a simply transitive action of the perverse bundle structures on $(Q,i,a)$ (both over $\mathbb{C}$ and in families).

It is easy to compute from the deformation theory of pairs $(Q,i)$ that the data $a$ are dual to the tangent space to $\text{PS}(X,V)$ at $(Q,i)$. However we would like to be more precise in the identification of the moduli of $D$-bundles as (the stack analog of) a twisted cotangent bundle in the sense of [BB], i.e. as (pseudo)torsor for the cotangent bundle equipped with a compatible symplectic form. Recall that two standard constructions of a twisted cotangent bundle are as the affine bundle of connections on a line bundle [BB], and as a “magnetic cotangent bundle” [OPRS], a Hamiltonian reduction at a one-point coadjoint orbit. The two constructions agree in the case of reduction at a coadjoint orbit coming from a character of the group, which produces the affine bundle of connections on the line bundle obtained by descending the trivial line bundle with equivariant structure given by the character.

We will describe both the perverse bundle and the $D$-bundle spaces as Hamiltonian reductions at (zero and nonzero, respectively) integral one-point orbits from the cotangent bundle of the relevant Quot-type scheme. Recall from [BD] (Section 1.2) that the very definition of the cotangent bundle of a stack is naturally given as a Hamiltonian reduction (at 0) of the cotangent bundle of a cover. Thus perverse bundles naturally form the cotangent bundle of a Quot scheme, while $D$-bundles form the space of connections of a line bundle which we identify with the dual of the determinant line bundle.

Remark 5.1. In addition to its concrete flavor, the description of $PB$ and $CM$ via Hamiltonian reduction from a Quot scheme also has an implicit advantage. Namely, it is easily adapted to capture the cotangent and twisted cotangent stacks $PB$ and $CM$ as derived (or dg) stacks, rather than naively as stacks.
Let \( \tilde{\mathcal{P}}_n(X, V) \) denote the moduli space of triples \((Q, i, \tau)\) where \((Q, i) \in \mathcal{P}_n(X, V)\) and \(\tau : \mathbb{C}^n \cong H^0(Q)\) is a basis of sections of \(Q\). The datum of \(\tau\) is equivalent to that of a surjection \(\tau : \mathbb{C}^n \otimes O \rightarrow Q\) (that induces an isomorphism \(\mathbb{C}^n \rightarrow H^0(Q)\)), so that \(\tilde{\mathcal{P}}_n(X, V)\) is the fiber product (over length \(n\) sheaves \(Q\)) of \(\mathcal{P}_n(X, V)\) with an open set of the Quot scheme parametrizing \(n\)-dimensional quotients \(\tau\). As an immediate consequence of this description one has:

**Lemma 5.2.** The space \(\tilde{\mathcal{P}}_n(X, V)\) is a smooth variety.

Note that \(\mathcal{P}_n(X, V) = \tilde{\mathcal{P}}_n(X, V) / GL_n\), where \(GL_n\) acts by changing the basis of \(H^0(Q)\).

**Lemma 5.3.** The cotangent bundle of \(\tilde{\mathcal{P}}_n(X, V)\) is the stack of quadruples \((Q, i, q, r)\) with \((Q, i, q)\) as above and

\[
(5.1) \quad r : Q[-1] \rightarrow \text{Cone}(V \oplus O^n \xrightarrow{(i,q)} Q) \otimes \Omega.
\]

**Proof.** First suppose that \(X\) is projective. Then a standard calculation gives

\[ T^*(\tilde{\mathcal{P}}_n(X, V)) = \text{Hom}(V \oplus O^n \xrightarrow{(i,q)} Q, Q) \]

and the lemma follows by Serre duality. If \(X\) is only quasiprojective, we complete \(X\) to a projective curve \(Y\) (and extend \(V\)) and apply the above argument to \(Y\); the lemma then follows by noting that all of our data \((Q, i, q, r)\) are in fact supported on \(X \subseteq Y\).

**Remark 5.4.** From this point forward, we may always assume that \(X\) is projective. Indeed, if not, then we may complete \(X\) to a projective curve \(Y\) (and extend \(V\)) and apply the above argument to \(Y\); the conclusions of Proposition 5.6 and Theorem 5.9 will apply to \(X\) as well.

**Lemma 5.5.** The moment map for the action of \(GL_n\) on \(T^*\tilde{\mathcal{P}}_n(X, V)\) lifting the action on \(\tilde{\mathcal{P}}_n(X, V)\) is the map

\[ T^*\tilde{\mathcal{P}}_n(X, V) \rightarrow \text{Hom}(O^n[-1], O^n \otimes \Omega) \cong \mathfrak{gl}_n \]

assigning to \((Q, i, q, r)\) the composition

\[ O^n[-1] \xrightarrow{q[-1]} Q[-1] \xrightarrow{\tau} \text{Cone}(V \oplus O^n \xrightarrow{(i,q)} Q) \otimes \Omega \xrightarrow{\text{can}} O^n \otimes \Omega, \]

where \(\text{can}\) is the canonical map from the cone of a morphism to (a summand of) its source.

**Proposition 5.6.** The stack \(\mathcal{P}_B(X, V)\) is canonically identified with the Hamiltonian reduction

\[ T^*\tilde{\mathcal{P}}_n(X, V) \sslash_0 GL_n \]

of \(T^*\tilde{\mathcal{P}}_n(X, V)\) at the moment value 0, i.e. to the cotangent stack to \(\mathcal{P}_n(X, V)\).

**Proof.** Maps \(r\) as in (5.1) that satisfy the vanishing moment condition define and are defined by maps

\[ \tau : Q[-1] \rightarrow \text{Cone}(V \xrightarrow{i} Q) \otimes \Omega. \]

The proposition then follows from Theorem 4.6. \(\square\)
Lemma 5.7. The canonical morphisms
\[(5.2) \ Ext^1(Q, Q \otimes \Omega) \leftarrow Ext^1(Q, \mathcal{O}^n \otimes \Omega) \to Ext^1(\mathcal{O}^n, \mathcal{O}^n \otimes \Omega)\]
are both isomorphisms.

Proof. First observe that all three vector spaces have dimension $n^2$. The left arrow
is surjective (hence an isomorphism) due to the vanishing of $Ext^2$’s. The right
arrow is dual to the map $\text{Hom}(\mathcal{O}^n, Q) \leftarrow \text{Hom}(\mathcal{O}^n, \mathcal{O}^n)$, which is injective (hence
an isomorphism) since the kernel of $\mathcal{O}^n \to Q$ has no global sections. □

Let $\mathcal{J}^1$ denote the sheaf of one-jets of functions on $X$. Let $[X] \in H^1(\Omega^1)$ be the
canonical nonzero class (i.e. the fundamental class of $X$).

Lemma 5.8. The image of the extension class $[\mathcal{J}^1(Q)] \overset{\text{def}}{=} [Q \otimes \mathcal{J}^1] \in \text{Hom}(Q[-1], Q \otimes \Omega)$
in $Ext^1(\mathcal{O}^n, \mathcal{O}^n \otimes \Omega)$ under the isomorphism of (5.2) equals $[X] \otimes \mathcal{O}^n$.

Proof. In the case $Q = \mathcal{O}_p$, $p \in X$ the assertion follows immediately from the
observation that the tautological extension of $\mathcal{O}_p$ by $\mathcal{O}_p \otimes \Omega$, Serre dual to the
identity map of $\mathcal{O}_p$, is given by one-jets. This class is identified using (5.2) (and
the functoriality of Serre duality) with the Serre dual to the identity map of $\mathcal{O}_X$, i.e. the fundamental class $[X]$. The statement of the lemma is now immediate
for $Q = \bigoplus_i \mathcal{O}_{p_i}$ where $p_1, \ldots, p_n$ are points of $X$, and follows for general $Q$ by
continuity. □

We will now perform hamiltonian reduction from $T^*\tilde{\text{PS}}_n(X, V)$ at a nontrivial
moment value, corresponding to the dual of the determinant character of $GL_n$. More precisely, the extension class
$[X]^n := [X] \otimes \mathcal{O}^n \in \text{Hom}(\mathcal{O}^n[-1], \mathcal{O}^n \otimes \Omega) = \mathfrak{gl}_n^*$
corresponds to the determinant character; we will take the hamiltonian reduction of $T^*\tilde{\text{PS}}_n(X, V)$ at $-[X]^n$.

Theorem 5.9. The Calogero-Moser stack $\text{CM}_n(X, V)$ is isomorphic, as a pseudo-
torsor over $\text{PB}_n(X, V) = T^*\tilde{\text{PS}}_n(X, V)$, to the hamiltonian reduction
$T^*\tilde{\text{PS}}_n(X, V)/\sim [X]^n GL_n$,

i.e. to the twisted cotangent bundle to $\text{PS}_n(X, V)$ associated to the dual determinant line bundle.

Proof. Let $(Q, i, q) \in \tilde{\text{PS}}_n(X, V)$ be a framed torsion sheaf with a basis. We wish
to show the equivalence of CM data $a : Q \otimes \mathcal{D}^1[-1] \to \text{Cone}(V \to Q)$, satisfying the
condition on its restriction to zeroth order differential operators, and of cotangent
data $r$ as above, satisfying the moment condition.
Since $\mathcal{J}^1$ is the dual of $\mathcal{D}^1$, the data of the map $a$ is equivalent to that of a map
$$a_1 : Q[-1] \to \text{Cone}(\mathcal{J}^1 V \xrightarrow{\mathcal{J}^1(q)} \mathcal{J}^1 Q)$$
such that the composite map
$$Q[-1] \to \text{Cone}(\mathcal{J}^1 \otimes (V \to Q)) \to \text{Cone}(V \to Q)$$
is the standard one (“inclusion of $Q$”). The datum of $a_1$ is similarly equivalent to
the choice of a map
\[
a_2 : Q[-1] \rightarrow \text{Cone}(V \otimes \Omega \xrightarrow{\mathcal{J}^1(V \otimes \Omega)} J^1Q)
\]
such that the composite
\[
a_2 : Q[-1] \rightarrow \text{Cone}(V \otimes \Omega \xrightarrow{\mathcal{J}^1(V \otimes \Omega)} J^1Q) \to Q[-1]
\]
is the identity.

Next, note that our condition on $a_2$ implies that the composite
\[
(5.3) \quad Q[-1] \xrightarrow{a_2} \text{Cone}(V \otimes \Omega \xrightarrow{\mathcal{J}^1(V \otimes \Omega)} J^1Q) \to \text{Cone}(Q \otimes \Omega \rightarrow J^1(Q))
\]
is inverse to the canonical quasi-isomorphism $\text{Cone}(Q \otimes \Omega \rightarrow J^1(Q)) \simeq Q[-1]$. Consequently, if we compose (5.3) with the further projection to $Q \otimes \Omega$, the resulting class in $\text{Hom}(Q[-1], Q \otimes \Omega)$ is exactly $[J^1(Q)]$. Let $\pi_2 : Q[-1] \rightarrow V \otimes \Omega$ be the result of composing $a_2$ with the projection on $V \otimes \Omega$. The above then shows that the composite
\[
Q[-1] \xrightarrow{\pi_2} V \otimes \Omega \xrightarrow{i \otimes \Omega} Q \otimes \Omega
\]
also gives $[J^1(Q)] \in \text{Hom}(Q[-1], Q \otimes \Omega) = \text{Ext}^1(Q, Q \otimes \Omega)$.

We now define a map
\[
\tilde{r} : Q[-1] \rightarrow (V \otimes \Omega) \oplus (\mathcal{O}^n \otimes \Omega)
\]
by $\tilde{r} = (\pi_2, -q^V)$, where $q^V \in \text{Ext}^1(Q, \mathcal{O}^n \otimes \Omega)$ corresponds to $J^1Q$ under the first identification of (5.2). It follows that the composite
\[
Q[-1] \xrightarrow{\tilde{r}} (V \otimes \Omega) \oplus (\mathcal{O}^n \otimes \Omega) \xrightarrow{(i+q) \otimes \Omega} Q \otimes \Omega
\]
is
\[
(i \otimes \Omega) \circ \pi_2 - (q \otimes \Omega) \circ q^V = [J^1(Q)] - [J^1(Q)] = 0.
\]
As a result, we get a lift $r$ of $\tilde{r}$ to $\text{Cone}((i + q) \otimes \Omega)$. To see that $r$ satisfies the moment condition, we compute that
\[
can \circ r \circ q[-1] = -q^V \circ q[-1],
\]
which equals $-[X]^n$ by Lemma 5.8.

Conversely, given $r$ as above, we find that its restriction to a map $Q[-1] \rightarrow V \otimes \Omega$ composes with $q \otimes \Omega$ to define the one-jet map $Q[-1] \rightarrow Q \otimes \Omega$. It follows that we may use it to define a map $a_2$ as above, and hence a map $a$ satisfying the restriction condition as desired.

Clearly all the identifications are $GL_n$-equivariant and preserve the torsor structures over the cotangent structures of the $PS_n(X, V)$. The theorem follows.

6. Explicit Description of CM Matrices for $\mathbb{A}^1$

In this section we illustrate in detail how our description of $\mathcal{D}$-bundles specializes, in the case of the affine line, to the familiar Calogero-Moser space description. In other words we want to spell out the correspondence between:

1. quadruples
\[
(X, Y, i, j) \in \mathfrak{gl}_n \times \mathfrak{gl}_n \times \mathbb{C}^n \times (\mathbb{C}^n)^* \quad \text{satisfying the CM relation } [X, Y] - ij + I = 0 \text{ (which we call “CM quadruples”)}
\]
up to simultaneous conjugation and
(2) our data for $\mathcal{O}$-framed $\mathcal{D}$-bundles on $\mathbb{A}^1$ with local second Chern class $n$, consisting of a length $n$ torsion sheaf $Q$, a framing map $\mathcal{O} \to Q$, and an action map $\mathcal{D}^1 \otimes Q[-1] \to \text{Cone}(\mathcal{O} \to Q)$ (defined in the derived category, i.e. up to homotopy) that agrees with the usual map on $\mathcal{O} \otimes Q \subset \mathcal{D}^1 \otimes Q$.

To summarize the relationship concisely: the matrix $X$ describes the sheaf $Q$, the vector $i$ describes the framing map (justifying our general notation for the latter), and $Y$, $j$ provide the components of the action morphism $a$.

**Remark 6.1.** It is important to note that a CM quadruple corresponds to a unique triple $(Q, i, a)$ but where $a$ is only well defined up to homotopy. What we will find below is that, once we replace $Q[-1]$ by a resolution, we can produce a canonical representative of the homotopy class of $(Q, i, a)$, and from this we can read off the CM quadruple completely explicitly.

Choosing a basis for $H^0(Q)$, we may identify $Q$ with $\mathbb{C}^n$. A choice of $\mathbb{C}[x]$-module structure on $\mathbb{C}^n$ is given by an $n \times n$ matrix $X$, and we then get a presentation of $Q$ by

$$
0 \to \mathbb{C}[x]^n \xrightarrow{x \cdot X} \mathbb{C}[x]^n \to Q \to 0
$$

where the last map takes $f(x) \otimes v$ to $f(X)v$ for $v \in \mathbb{C}^n = Q$. Our Koszul data, then, take the form

$$
\xymatrix{
\mathcal{D}^1 \otimes \mathbb{C}[x]^n 
\ar[r]^\partial & \mathbb{C}[x] \ar[d]^i \otimes (x - X) \\
\mathcal{D}^1 \otimes \mathbb{C}[x]^n 
\ar[r]^\partial & \mathbb{C}^n.
}
$$

Since all maps are required to be $\mathbb{C}[x]$-linear, the map $\partial_0$ is determined by its values on vectors in $\mathbb{C}^n$ and elements of the form $\partial \otimes v$ for $v \in \mathbb{C}^n$. Since we require the morphism of complexes to give the standard one on $\mathcal{O} \otimes Q$, we find that $\partial_0(v) = 0$ for $v \in \mathbb{C}^n$; we write $\partial_0(\partial \otimes v) = j(x)v$ where $j(x) : \mathbb{C}^n \to \mathbb{C}[x]$ is a $\mathbb{C}$-linear map. This completely determines $\partial_0$. Similarly, we may write $i = i(1)$, which determines $\iota$.

By $\eqref{6.1}$, $\partial_1(f(x) \otimes v) = j(X)v$. We may write $\partial_1(\partial \otimes v) = j(X)v$ for all $v \in \mathbb{C}^n$, where $Y$ is an appropriate $n \times n$ matrix. Applying $\partial_1 \circ (1 \otimes (x - X))$ and $\iota \circ \partial_0$ to an element of the form $\partial \otimes v$, we may compute that the square $\eqref{6.2}$ commutes if and only if the following equation is satisfied:

$$
I + XY - YX = i \cdot j(X).
$$

Hence our Koszul data are determined by a choice of $(X, Y, i, j(x))$ satisfying this equation. It is immediate that one has the following converse: given a CM quadruple $(X, Y, i, j)$ satisfying the CM relation, the diagram of complexes defined as above (with $j(x) = j$) gives our $\mathcal{D}$-bundle data.

It remains to show that, the diagram corresponding to a quadruple $(X, Y, i, j(x))$ is homotopic to a unique diagram corresponding to a CM quadruple. A homotopy of our complex is a diagonal “lower left to upper right” map $h : \mathcal{D}^1 \otimes \mathbb{C}[x]^n \to \mathbb{C}[x]$.

We first choose this map to vanish on elements $f(x) \otimes v$, $v \in \mathbb{C}^n$, and to take the form $h(\partial \otimes v) = h_\partial(x)(v)$ for a linear map $h_\partial(x) : \mathbb{C}^n \to \mathbb{C}[x]$. A computation then shows that, modifying our original complex by the homotopy, the data $(X, Y, i, j(x))$ are replaced by

$$(X, Y + h_\partial(X), i, j(x) + xh_\partial(x) - h_\partial(x) \cdot X).$$
In particular, one may check that, writing \( j(x) = j + xj' \) where \( j' : \mathbb{C}^n \to \mathbb{C}[x] \) is a linear map, one can solve the equation \( j(x) + xh_\partial - h_\partial(x) \cdot X = j \) for \( h_\partial(x) \). Consequently, up to homotopy, we can replace \((X, Y, i, j)\) by a CM quadruple giving the same homotopy class of Koszul data.

To complete the proof, we start from a CM quadruple \((X, Y, i, j)\) and consider an arbitrary homotopy \( h \). As before, we write \( h_\partial(x)(v) \) for \( h(\partial \otimes v) \). The formula above shows that, after modifying by the homotopy, \( j \) is replaced by \( j + xh_\partial(x) - h_\partial(x) \cdot X \), which, in particular, has degree greater than zero in the variable \( x \).

So if modifying \((X, Y, i, j)\) by \( h \) gives another CM quadruple \((X', Y', i, j')\) then \( h_\partial = 0 \). Moreover, it is easy to check that the new map \( J' \) obtained after applying \( h \) satisfies \( J'(v) = xh(v) - h(Xv) \). Writing the linear map \( h : \mathbb{C}^n \to \mathbb{C}[x] \) as a polynomial \( \sum_{i=0}^k x^i h_i \) with covector coefficients \( h_i \), we find that if \( h_k(v) \neq 0 \) then \( \deg xh(v) = k + 1 > \deg h(Xv) \). Since we require \( J'(v) = 0 \) for all \( v \in \mathbb{C}^n \), we conclude that \( h(v) = 0 \) for all \( v \in \mathbb{C}^n \). Together with the vanishing of \( h_\partial \), this proves that \( h = 0 \), i.e. there is a unique CM quadruple in a given homotopy class of our Koszul data. This completes the correspondence.
