GEOMETRY ON LIE ALGEBROIDS I:
COMPATIBLE GEOMETRICAL STRUCTURES ON THE BASE

ALEXEI KOTOV AND THOMAS STROBL

ABSTRACT. The object of our study is a Lie algebroid $A$ or a Cartan-Lie algebroid $(A, \nabla)$ (a Lie algebroid with a compatible connection) over a base manifold $M$ equipped with appropriately compatible geometrical structures. The main focus is on a Riemannian base $(M, g)$, but we also consider symplectic and generalized Riemannian structures.

For the Riemannian case, we show that the compatibility implies that the foliation induced by the Lie algebroid is a Riemannian foliation; thus, in particular, if the leaf space $Q = M/\sim$ is smooth, $Q$ permits a metric such that the quotient projection is a Riemannian submersion. For other structures on $M$ with a smooth leaf space $Q$, the reduced geometrical type on $Q$ can be different: for example, $(M, \omega)$ symplectic provides in general only a symplectic realization of a Poisson manifold $(Q, \mathcal{P})$.

Building upon a result of del Hoyo and Fernandes, we prove that any Lie algebroid integrating to a proper Lie groupoid admits a compatible Riemannian base. We also show that, given an arbitrary connection on an anchored bundle, there is a unique Cartan connection on the corresponding free Lie algebroid.

Key words and phrases: Lie algebroids, Riemannian foliations, symplectic realization, generalized geometry, symmetries, gauge theories, reduction.

Lie algebroids were introduced in the 1960s by Pradines [22] as a formalization of ideas going back to works of Lie and Cartan. By definition it is a Lie algebra structure on the sections of a vector bundle $A \to M$ which in turn is equipped with a bundle map $\rho: A \to TM$ such that for every pair of sections $s, s' \in \Gamma(A)$ and every function $f \in C^\infty(M)$ one has the Leibniz rule $[s, fs'] = f[s, s'] + (\rho(s)f)s'$. They combine usual geometry and Lie algebra theory below a common roof, interpolating between tangent bundles and foliation distributions on the one hand and Lie algebras and their actions on manifolds on the other hand. Correspondingly, Lie algebroids provide a particular way to generalize notions of ordinary geometry to geometry on them: Typical examples include the generalization of the de Rham differential, $A^d: \Gamma(\Lambda^\bullet A^\ast) \to \Gamma(\Lambda^{\bullet+1} A^\ast)$, Lie algebroid covariant derivatives $A\nabla$, where sections $\psi$ of another vector bundle $V$ over the same base can be differentiated along sections $s$ of $A$, $A\nabla_s \psi \in \Gamma(V)$, together with a notion of its curvature or torsion, or the fact that any fiber metric $A^g$ on $A$ induces a unique $A$-torsion-free, metrical $A$-connection on $A$. Likewise, notions from standard Lie theory generalize to this setting: For example, representations of a Lie algebra on a vector space are replaced here by flat $A$-connections on vector bundles.

Most importantly, however, there is a relation of Lie algebroids to Lie groupoids that reduces to the one of Lie algebras to Lie groups for the case of a pointlike base. But while any Lie groupoid $\mathcal{G} \xrightarrow{s} M$ gives rise to a Lie algebroid $A \to M$ by identifying sections of $A$ with left-invariant vector fields in the kernel of $dt$ on $\mathcal{G}$, the reverse direction, Lie third theorem, does not hold in all generality: not any Lie algebroid integrates to a Lie groupoid. The necessary and sufficient conditions of integrability were found by Crainic and Fernandes in [6]. In this case, there then is a unique $s$-simply connected, connected Lie algebroid integrating the given Lie algebroid. For $A = TM$, e.g., which is always integrable, this is its fundamental groupoid $\mathcal{G} = \Pi_1(M)$, whose elements consist of homotopy classes of paths with fixed endpoints.

The purpose of the present paper is to investigate the interplay between Lie algebroids and additional ordinary geometrical structures defined on them. These structures together with the appropriate compatibilities are inspired by mathematical physics, where they appear naturally in the context of gauge theories, cf. [15, 16] for the corresponding

---

1For a foliation $\mathcal{F}$ in $M$, one puts $A = T\mathcal{F}$, the tangent distribution to the foliation, the anchor $\rho$ is the natural embedding and the bracket the Lie bracket of vector fields. In the case of only one leaf, one obtains the standard Lie algebroid $A = TM$. Given the action of a Lie algebra $\mathfrak{g}$ on a manifold $M$, one puts $A = M \times \mathfrak{g}$, $\rho$ results from the restriction of the fundamental vector field of a given Lie algebra element to the respective point in the base, and the Lie bracket of constant sections is extended to all sections by the Leibniz rule. For $M$ reducing to a point, this, as well as in fact the general definition, reduces to an ordinary Lie algebra. A rather generic example of a Lie algebroid is given by the cotangent bundle of a Poisson manifold, where the anchor is given by contraction with the bivector field and the bracket $[df, dg] := d\{f, g\}$ is extended by means of the Leibniz rule. We will assume acquaintance to Lie algebroids and Lie groupoids throughout this paper, cf., e.g., [2, 17, 19] for the necessary background material. Except if otherwise stated, we work with finite dimensional vector bundles in the smooth category always.
papers in physics as well as the subsequent section, Sec. 2, for a summary in a purely mathematical language. There are different options of interest in this context. All of them have in common that $A$ is equipped with an ordinary connection $\nabla$.

One of the natural questions posing itself is thus the one of a good compatibility of $\nabla$ with a Lie algebroid structure on $A$. An evident option is that $\nabla$ should preserve the bracket. This is too restrictive, however: Suppose, for example, that $A = T^*M$ for a Poisson manifold $(M, \Pi)$. Then such a condition corresponds to $\nabla \Pi = 0$, restricting $\Pi$ to have constant rank and thus excluding most of the interesting examples of Poisson manifolds. Another natural option is the following one: Any ordinary connection on $A$ gives rise to a very trivial $A$-connection by $\nabla \cdot = \nabla \rho(\cdot)$. This does not yet contain information about the Lie bracket on $A$. However, there is a notion of a duality of $A$-connections on a Lie algebroid (cf. [2]), $A \nabla \mapsto A \nabla^*$, where $A \nabla^* s' = [s, s'] - A \nabla s' s$. One then may ask the $A$-curvature of $A \nabla^*$ to vanish. This is too weak now, however, since for a bundle of Lie algebras, $A$ with $\rho \equiv 0$, this conditions becomes vacuous, where here we would very much like to preserve the bracket.

As we will explain in Sec. 3 the searched-for good notion is the following one: Any connection in $A$ gives a splitting of $J^1(A) \to A$, where $J^1(A)$ denotes the first jet bundle of sections of $A$. Since $J^1(A)$ carries a natural Lie algebroid structure induced by $A$, we require the $\nabla$-induced splitting to be a Lie algebroid morphism. This condition implies indeed that $A R_{A \nabla} = 0$, reduces still to the wished-for constancy of the bracket for bundles of Lie algebras, and, as we will show, reproduces the mathematically much less transparent formulation as found in the context of mathematical physics. We call a compatible couple $(A, \nabla)$ a Cartan-Lie algebroid. We refer the reader to [2, 3] for more details concerning Cartan connections on Lie algebroids and to [9] for the role of $A$-connections.

In the applications, the bundle $A$ will then equipped with additional geometric structures, like a Riemannian metric $g$ on the base or a fiber metric $A g$ on the bundle. In the present paper, we will focus on geometrical structures defined on $M$, starting in Sec. 4 with Riemannian ones. The compatibility that a metric $g$ on the base of a Lie algebroid $A$ is required to satisfy will be of the form

\begin{equation}
\tau^\nabla g = 0,
\end{equation}

where $\tau^\nabla$ is an $A$-connection on $TM$, intertwined by $\rho$ with $A \nabla^*$ introduced above. Since the transition to $TM$ implies also replacing the Lie bracket on $A$ by the canonical bracket of vector fields, the condition (1) does in fact only depend on the anchor $\rho: A \to TM$ and thus can be formulated for any anchored bundle already. While some of the statements in this paper will be formulated for this enlarged setting, one of the main results of the present paper requires a Lie algebroid that is even integrable to a proper Lie groupoid. Proper here means that the map $s \times t: \mathcal{G} \times \mathcal{G} \to M$ is proper, i.e. compact subsets of $M$ have compact pre-images, thus these are those Lie algebroids which generalise compact Lie algebras. Building on a result of del Hoyo and Fernandes [8], we show that any such a Lie algebroid admits a metric $g$ satisfying Eq. (1).

\footnote{For simplicity, we sometimes write simply $A$ for the Lie algebroid data $(A, \rho, [\cdot, \cdot])$. Depending on the context, $A$ either denotes a Lie algebroid or only its underlying vector bundle.}
We call a metric \( g \) compatible with a Lie algebroid \( A \) in the sense of Eq. (1) a Killing Lie algebroid. Although this name is difficult to generalize to other geometrical structures, it expresses the close relation of it to symmetries of the geometric structure on the base, here the metric: Indeed, the image with respect to the anchor of any (locally) covariantly constant section is rather easily seen to be a (local) Killing vector field of \( g \). Be there Killing vectors of the metric \( g \) on \( M \) or not, the notion also guarantees good quotients whenever the leaf-space of the Lie algebroid permits a good quotient; in this case the natural projection map becomes a Riemannian submersion. A natural generalization of Riemannian submersions to singular foliations are Riemannian foliations [20]. We will show that the natural foliation of \( M \) induced by any Killing Lie algebroid is a Riemannian foliation. If the reverse is true, i.e. if any Lie algebroid \( A \) equipped with a Riemannian metric \( g \) on its base can be equipped with a connection \( \nabla \) so that the data become those of a Killing Lie algebroid, is an interesting problem left open in this article. Some simple examples and facts about Killing Lie algebroids where the connection \( \nabla \) on \( A \) is flat, are deferred to an appendix, App. A.

In Sec. 5, we briefly consider other geometrical structures on the base, without developing this subject in the present paper to much of a depth. The reason for this is two-fold: First, while also for other compatible geometrical structures on the base of a Lie algebroid with a smooth leaf space \( Q = M/\mathcal{F} \) permit the geometric structure to descend to the quotient in some way, the resulting structure on \( Q \) can be of a different type. We will illustrate this with a symplectic structure, where on the quotient one induces a Poisson structure, so that \((M, \omega) \to (Q, \Pi_Q)\) provides a symplectic realization of this quotient. The second reason is that some considerations in string theory suggest a more general compatibility condition than Eq. (1) induced by a single connection \( \nabla \) on \( A \). We want to show how these structures can be hosted as well in the present framework and related in this particular context to what is called now generalized geometry [11].

While some of the examples of Sec. 4 will have mutual compatibility of \( A, \nabla, \) and \( g \), thus forming a Killing Cartan Lie algebroid, for the main part of them \( \nabla \) will not be Cartan also; in particular this is not guaranteed for those Killing Lie algebroids integrable to proper Lie groupoids obtained here. On the other hand, as mentioned already above, the compatibility requirement Eq. (1) is already well-defined for any anchored bundle, i.e. any bundle \( E \to M \) together with a bundle map \( \rho: E \to TM. \) In Sec. 6, we thus prove the following theorem: Given any anchored bundle \((E, \rho)\) over a Riemannian base \((M, g)\), equipped with a connection \( \nabla \) on \( E \) such that Eq. (1) holds true, there exists an infinite-rank free Cartan Killing Lie algebroid \((FR(E), \nabla, g)\) extending these data.

Every vector space gives naturally rise to a free infinite-dimensional Lie algebra. Applying the same strategy to a vector bundle needs some more care due to compatibility with the anchor map \( \rho \), which, as a simple consequence of the Lie algebroid axioms, is required to become a morphism of the brackets. This implies in particular that in general the image of the anchor map will increase within this process. Calling the resulting Lie algebroid \( FR(E) \to M \) we then show that the initial connection on \( E \subset FR(E) \) can be extended to all of \( FR(E) \) such that it now becomes Cartan and, moreover, the metric \( g \) stays compatible with this extended connection in the sense of Eq. (1) again. Moreover, this construction is universal: Every connection-preserving morphism from \((E, \nabla, g)\) to
a Cartan Killing Lie algebroid \((A, \nabla, g)\) such that the base map is the identity factors through this free Cartan Killing Lie algebroid.

There are two important questions which we leave open in this final section: first, what are conditions such that the Lie algebroid \(FR(E)\), which is finitely filtered, but of infinite rank, can be truncated to a finite rank Cartan Killing Lie algebroid \((A, \nabla, g)\). And second, under which conditions does the (unmodified finite dimensional) base \(M\) of \(FR(E)\) carry a singular foliation: in the infinite rank setting, involutivity of the image of the anchor map \(\rho_{FR(E)}\) is easily seen to not be sufficient for integrability of the singular distribution on the base.

Acknowledgements. We are grateful to Matias del Hoyo, Rui Fernandes, Camille Laurent-Gengoux, Llohann Sperança and Alan Weinstein for their interest and useful discussions. Likewise we thank Anton Alekseev, Jim Stasheff and Marco Zambon for remarks on the manuscript. This research was partially supported by Projeto P.V.E. 88881.030367/2013-01 (CAPES/Brazil), the project MODFLAT of the European Research Council (ERC), and the NCCR SwissMAP of the Swiss National Science Foundation. We are grateful for this support.

2. Motivation via Mathematical Physics

Physics often points to new, mathematically interesting notions, worth being studied in their own right, and selecting the “right choice” out of a variety of otherwise conceivable options. The present article implicitly pursues such a study, suggested by a generalization of gauge theories of the Yang-Mills type where the structure group or Lie algebra is replaced by a structural Lie groupoid/algebroid. While keeping the main text below as well as eventual sequels to this article mathematically self-contained without it, we provide a short summary of this motivation here (for more details cf. our previous, more physics oriented articles [15, 16] as well as [18, 5]).

Standard sigma models are defined after selecting a source (pseudo) Riemannian manifold \((\Sigma, h)\) and a target Riemannian manifold \((M, g)\). This gives rise to a functional \(S_0[X]\) on the space of maps \(X\) from \(\Sigma\) to \(M\), the Euler-Lagrange equations of which are harmonic maps. The isometry/symmetry group \(G\) of \((M, g)\) lifts to \(S_0\). “Gauging” of this symmetry group \(G\) then amounts to the following procedure: One considers a \(G\)-principal bundle \(P\) over \(\Sigma\). For simplicity, we restrict to a trivial and trivialized bundle \(P := \Sigma \times G\). Gauging is effectuated by introducing a connection in \(P\) as an additional “field”, which we may identify with a \(g\)-valued 1-form \(A\) on \(\Sigma\), where \(g = \text{Lie}(G)\). Replacing the tangent map \(dX\) of \(X\) by its covariantization \(DX := dX - \rho(A)\) in the original functional \(S_0\), where the bundle map \(\rho: M \times g \to TM\) encodes the \(g\)-action on \(M\), one obtains a new functional \(S_1[X, A]\). This “gauged theory” \(S_1\) has the enhanced symmetry group \(C^\infty(\Sigma, G)\), which is called the group of gauge transformations.

---

3One may omit reading this section without loss of the mathematical content of the present article. This section is just meant to indicate, in a mathematical language, from where some of the notions considered here originate, simultaneously giving them additional meaning.
Both of the “fields” together, the maps $X \in C^\infty(\Sigma, M)$ called scalar fields, as well as the connection 1-forms $A \in \Omega^1(\Sigma, \mathfrak{g})$, called gauge fields, can be reinterpreted as a vector bundle morphism $a: T\Sigma \to A$, where $A = M \times \mathfrak{g}$ may be viewed as an action Lie algebroid. The Killing equation expressing the isometry of $\mathfrak{g}$ on $M$ with respect to the Lie algebra $\mathfrak{g}$ can be rewritten as follows: Consider the action Lie algebroid $(A, \rho, [\cdot, \cdot])$ over the Riemannian manifold $(M, g)$ together with the canonical flat connection $\nabla$ on $A$ such that

\begin{equation}
(\nabla (\iota_\rho g))_{\text{sym}} = 0.
\end{equation}

Here $\iota_\rho g = g(\rho, \cdot) \in \Gamma(A^* \otimes T^*M)$ and for the $TM$-part of $\nabla$ one uses the Levi-Civita connection of $g$. The main observation coming from mathematical physics of relevance for the present article is that one can introduce a gauged theory of scalar fields for the triple $(A, \nabla, g)$ of a general Lie algebroid $A$ equipped with a connection and defined over a Riemannian base $(M, g)$ provided the compatibility equation (2) is satisfied \[15\]. We call such a triple a Killing Lie algebroid, since for any constant section $s \in \Gamma(A)$, $\nabla s = 0$, the vector field $\rho(s)$ generates an infinitesimal isometry of $g$.

Let us be more specific here. “Gauging” in this generalized context, i.e., in particular, without necessarily isometries of $g$, applies to the following situation: One is given a functional $S_0$ depending on $X: \Sigma \to M$ as described above. Assume that there is a Lie algebroid $(A, \rho, [\cdot, \cdot])$ over $M$ equipped with a connection such that Eq. (2) is satisfied. In fact, for what follows it is sufficient to have an anchored bundle $(A, \rho)$ over $M$, with an integrable singular distribution $\rho(A) \subset TM$. Important is only that Eq. (2) holds true. Then there exists a functional $S_1$ depending on $a: T\Sigma \to A$ with the following properties:

1. $S_1$ restricted to such maps $a$ that map to the 0-section in $A$ coincides with $S_0$.
2. Vector fields along the foliation of $M$ tensored by functions over $\Sigma$ can be lifted to infinitesimal symmetries of $S_1$ (gauged transformations).
3. Whenever the quotient space $Q = M/\sim$ is smooth and $\Sigma$ is contractible, the equivalence classes of solutions to the Euler-Lagrange equations of $S_1$ modulo gauge symmetries are in one-to-one correspondence with solutions of an “ungauged” theory $S_0$ where $(M, g)$ is replaced by the quotient $(Q, g_Q)$.

In the last item, the leaf space is given by the orbits generated by $\rho(A)$; Eq. (2) then ensures that for smooth quotient $Q$ there is a unique metric $g_Q$ such that the projection from $M$ to $Q$ is a Riemannian submersion \[15\]. We also remark that the infinite-dimensional group of gauge symmetries is essentially defined already once the functional $S_1$ is given, cf., e.g., \[10\]. While the third condition or property makes sense only for smooth quotients $M/\sim$, the gauge theory is particularly interesting or useful precisely when this quotient is not smooth (otherwise one would not need the concept of the gauge theory).

Let $d$ be the dimension of the source manifold $\Sigma$, then the functional $S_0$ can be extended naturally, if one is given some $B \in \Omega^d(M)$, namely by adding its pullback by $X: \Sigma \to M$ to the original functional. In this way, by gauging one is led to consider $(A, \nabla, g, B)$, which, in addition to Eq. (2), has to satisfy

\begin{equation}
(\iota_\rho \circ D + D \circ \iota_\rho) B = 0.
\end{equation}
Here \( \iota_\rho \) denotes contraction with the \( TM \)-part of \( \rho \in \Gamma(A^* \otimes TM) \) and \( D \) is the exterior covariant derivative induced by \( \nabla \). The similarity of the two equations (2) and (3) becomes more transparent, when rewritten in the following way:

\[
\begin{align*}
\mathcal{L}_{\rho(s)} g &= 2 \text{Sym} \left( \iota_{(\text{id} \otimes \rho)} \nabla(s) g \right), \\
\mathcal{L}_{\rho(s)} B &= d \text{Alt} \left( \iota_{(\text{id} \otimes \rho)} \nabla(s) B \right),
\end{align*}
\]

which has to hold true for arbitrary sections \( s \in \Gamma(A) \). Here on the r.h.s. the map \( \rho: \Gamma(A) \to \Gamma(TM) \) is applied to the second factor in \( \nabla(s) \in \Gamma(T^*M \otimes A) \) and \( \text{Sym} \) and \( \text{Alt} \) denote the symmetrization and antisymmetrization projectors of the tensor product, respectively. Again, for constant sections \( s \in \Gamma(A) \), the vector fields \( \rho(s) \) generate symmetries of \( B \).

Eq. (3) can be used to motivate definitions in the context of (higher pre-) symplectic structures and reductions, and in fact so in potentially two different ways. We can either identify the (higher) symplectic form \( \omega \) directly with \( B \). Then, Eq. (3) suggests the form of an “covariantized (higher) symplectic equation” as \( [D, \iota_\rho] \omega = 0 \), or, \( \omega \) being closed, as

\[
D(\iota_\rho \omega) = 0.
\]

Note that for \( \nabla \) flat and \( e_a \) a covariantly constant basis, this equation reduces to \( \mathcal{L}_{\rho_a} \omega = 0 \), stating that the collection of vector fields \( \rho_a \) is symplectic and higher symplectic for \( d = 2 \) and \( d > 2 \), respectively. This is e.g. the case for the action Lie algebroid with its canonical flat connection. One certainly may also drop the non-degeneracy condition on \( \omega \), replacing “symplectic” by “pre-symplectic” in the above.

Another option, more natural from the sigma model perspective, is to identify \( \omega \) with \( H = dB \). Eq. (3) then is best reinterpreted as suggesting a “covariantized (higher) Hamiltonian equation” of the form:

\[
\iota_\rho \omega = Dh,
\]

where \( \omega \) is a (higher) symplectic form, \( \omega \in \Omega^{d+1}_{\text{cl}}(M) \) non-degenerate, and \( h \in \Omega^{d-1}_{\text{cl}}(M, A) \) a “covariantized (higher) Hamiltonian”. For \( d = 1 \), \( (M, \omega) \) is a symplectic manifold in the usual sense and the section \( h: M \to A^* \) a “covariantized moment map”. Again, this reduces to the ordinary definition of a moment map \( h: M \to \mathfrak{g}^* \) for the case of \( A = M \times \mathfrak{g} \). More generally, whatever \( A \) and \( \nabla \), if one has a constant sections \( s \), then \( \rho(s) \) is a Hamiltonian vector field with Hamiltonian \( h(s) \equiv \langle h, s \rangle \). Note that, in contrast to standard symplectic geometry, the covariantized Hamiltonian equation, Eq. (7), does not imply and is not a special case of the covariantized symplectic equation, Eq. (6) (except for zero curvature \( D^2 = 0 \)). In the present article we will consider the covariantized symplectic equation, postponing the Hamiltonian version to possibly later work.

There is yet another option of interpreting the couple of equations (4) and (5) for \( d = 2 \) of relevance for the present paper. This is related to the notion of a generalized metric, cf., e.g., [13]: An ordinary metric \( g \) on \( M \) together with a not further restricted 2-form \( B \in \Omega^2(M) \) can be viewed as a generalized metric \( \Phi = g + B \) on \( M \). It was seen in several instances already that strings are intimately related to generalized geometries, cf, e.g.,

\[\text{(A. Weinstein informed us, on the other hand, that he and C. Blohmann have work in progress on the Hamiltonian case with } d = 1. \text{ They call } (A, \nabla, \omega) \text{ for } d = 1 \text{ satisfying Eq. (7) } \text{Hamiltonian Lie algebroids.}\]
This corresponds to a theory with a worldsheet $\Sigma$ of two dimensions, $d = 2$. It is also precisely this dimension where the Hodge dual of a 1-form gauge field $A$ is again a 1-form. Thus, in $d = 2$, and only there, the equations (1) and (5) admit a generalization, corresponding precisely to the additional freedom in the choice for gauge transformations (cf. [5] for the details). While given a Lie algebroid $A$ over $M$, the compatibility for $g$ and $B$ required in Eq. (1) and Eq. (5) is parameterized by a connection $\nabla$ in $A$, now there is in addition a section $\psi \in \Gamma(T^*M \otimes \text{End}(A))$ in the correspondingly weakened conditions, which then read as follows:

\[
\mathcal{L}_\rho(s)g = 2 \text{Sym} \left( \ell_{(\text{id} \otimes \rho)} \nabla(s)g + \ell_{(\text{id} \otimes \rho)} \psi(s)B \right),
\]

\[
\mathcal{L}_\rho(s)B = 2 \text{Alt} \left( \ell_{(\text{id} \otimes \rho)} \nabla(s)B \pm \ell_{(\text{id} \otimes \rho)} \psi(s)g \right),
\]

to hold true for all sections $s \in \Gamma(A)$. The sign in the last term in the second line corresponds to the signature of the metric $h$ on $\Sigma$: one has a plus sign, if $h$ has a Lorentzian signature and a minus sign, if the string theory is of Euclidean signature. In the main text below, we will interpret the coupled equations (8) geometrically, using ideas from the realm of generalized geometry on $M$.

Except for maybe this last, more involved system (8), the guiding principle behind the notion one is tempted to introduce by the study of gauge theories should be clear by now: One always has a Lie algebroid $A$ with a connection $\nabla$. The base $M$ of $A$ is equipped with a geometrical structure $\mathcal{G} = \{g, \omega, \ldots\}$. Then there is a compatibility condition which implies that constant sections generate symmetries of $\mathcal{G}$ by means of the anchor $\rho$ (Eqs. (2), (6) or (3), (7), etc). Moreover, in the case that $A = M \times g$ is the action Lie algebroid with its canonical flat connection, one gets back the usual notions of Killing, (higher) symplectic, Hamiltonian, \ldots vector fields or the notion of a moment map. But even if one does not deal with such symmetries of $\mathcal{G}$ in the strict sense, the gauge theory formulation suggests that in such cases still a reduction is meaningful—mathematically certainly with the additional assumption of a smooth quotient, or, more contemporary, interpreting the data as describing a quotient stack, i.e. a particular smooth description of an otherwise singular quotient.

Let us return to the logic immanent to gauge theories again. Physically one is compelled to add also a “kinetic term” for the gauge fields, at least if they should correspond to propagating interaction particles. In the standard setting with the isometry Lie algebra $\mathfrak{g}$, one needs an ad-invariant metric on $\mathfrak{g}$ in this context. In the generalization of $M \times \mathfrak{g}$ to arbitrary Killing Lie algebroids $A$, this becomes a fiber metric $A^g$ on the vector bundle $A$ satisfying

\[
A^\nabla (A^g) = 0
\]

with respect to the Lie algebroid or $A$-covariant derivative\footnote{In the body of the paper, this $A$-connection is mostly denoted by $^A\nabla$, or by $^A\nabla^\ast$, so as to express that it is dual to the evident $A$-connection $^A\nabla = \nabla_{\rho(\cdot)}$ in a precise way, cf. Eq. (28) below. The $A$-torsion $^A\tilde{T}$ of $A^\nabla$ used below is the negative of the one of $^A\nabla$, denoted by $^A\tilde{T}$ in the main text; this difference in sign is important for comparison of formulas in this section with those in the rest of the paper.}

\[
A^\nabla s s' := [s, s'] + \nabla_{\rho(s')}s.
\]
Note that the second term in Eq. (10) induced by the ordinary connection $\nabla$ on $A$ renders the left-hand side $C^\infty(M)$-linear in $s$, as it has to be for an $A$-connection. On the other hand, for $A = M \times g$ with its canonical flat connection $\nabla$, this term vanishes for constant sections and one recognizes the ordinary adjoint action of $g$ on itself (mimicked by the constant sections of $M \times g$).

It is certainly to be expected that gauge invariance restricts the fiber metric $^A g$ in a natural way generalizing ad-invariance: and this turns out to be as described above. However, gauge invariance of the new kinetic term for the gauge fields yields also additional constraints on the previous data for the scalar fields, in particular on the Lie algebroid structure of $A$ and the connection $\nabla$. Denoting by $^A T \in \Gamma(A \otimes \Lambda^2 A^*)$ the $A$-torsion of Eq. (10), the required compatibility condition can be cast into the form:

$$\nabla (^A T) = 2 \text{Alt}(\iota_\rho F),$$

where $F \in \Gamma(A \otimes A^* \otimes \Lambda^2 T^* M)$ denotes the curvature of $\nabla$.

Despite obtained in a very specific context, the compatibility condition (11) is natural to consider for any Lie algebroid $A$ equipped with a connection—as we will demonstrate also in the body of the paper below from a purely geometrical perspective. We will thus consider this compatibility of the Lie algebroid structure with the connection also for other geometric structures $G$ in $(A, \nabla, G)$.

Eqs. (9), (10), and (11) were found already quite some time ago [18] in the context of sigma models. However, they came together with another condition, namely that $\nabla$ should be flat, $F = 0$. Together with Eq. (11) this would imply that locally $A$ has to be isomorphic to an action Lie algebroid; indeed, $^A T$ is a tensorial version of the Lie bracket of $A$ and, if covariantly constant, it implies that the Lie bracket of constant sections is constant. This led the authors of [18] to exclude a further study of this type of theories, since, together with $F = 0$ and Eq. (11), such theories would boil down to just the well-known standard Yang-Mills gauge theories (coupled to scalar fields). Only recently [16] a way to circumvent this restriction was found, relaxing the condition on $F$: Consider an $A$-valued 2-form $b \in \Gamma(\Lambda^2 T^* M \otimes A)$; its pull-back by $X: \Sigma \to M$ can be added to the (covariantized) curvature 2-form of the gauge field $A$. Then, gauge invariance of the correspondingly modified kinetic term for $A$ requires, in addition to Eq. (9) and Eq. (11), the following interesting condition:

$$F + (\iota_\rho \circ D + D \circ \iota_\rho) b - ^A T(b, \cdot) = 0.$$

The terms involving $b$ are reminiscent of Eq. (11); just since $b$ also has an $A$-component, the covariantized Lie derivative is accompanied by a covariant version of the adjoint action. In particular, for $A = M \times g$ with its flat connection, this equation implies simply that $b$ is $g$-invariant, $b \in \Omega^2(M, g)^0$. We intend to come back to a geometric meaning of Eq. (12) elsewhere.

---

6This is related to the fact that without the kinetic term for the gauge fields, one does not need the Lie algebroid structure and can live with just an anchored bundle. For the kinetic term of the 1-form gauge fields, we need $(A, \nabla)$ to carry a Lie algebroid structure, or at least to have an extension in terms of a Lie$_\infty$ algebroid.
3. Connections on Lie algebroids

Every vector bundle $E$ over $M$ gives rise to the short exact sequence

$$0 \longrightarrow T^*M \otimes E \longrightarrow J^1(E) \longrightarrow E \longrightarrow 0,$$

where $J^1(E)$ is the bundle of first jets of smooth sections of $E$. The embedding of $T^*M \otimes E$ into $J^1(E)$ is determined for every $f, h \in C^\infty(M)$ and $s \in \Gamma(E)$ by the following formula:

$$f \, dh \otimes s \mapsto f(hj_1(s) - j_1(hs)),$$

where $j_1(s) \in \Gamma(J^1(E))$ is the first jet-prolongation of $s$. Every connection $\nabla$ on $E$ is in one-to-one correspondence with a splitting $\sigma: E \to J^1(E)$ of (13):

$$\sigma(s) = j_1(s) + \nabla s,$$

where $\nabla s \in \Gamma(T^*M \otimes E)$ is identified with its image in $\Gamma(J^1(E))$.

Let $(A, \rho, [\cdot, \cdot])$ be a Lie algebroid over $M$. Now (13) becomes even an exact sequence of Lie algebroids. The bracket in $J^1(A)$ is defined such that taking the Lie brackets commutes with the prolongation of sections,

$$[j_1(s), j_1(s')] = j_1([s, s'])$$

for all sections $s, s' \in \Gamma(A)$, while its anchor is fixed by the morphism property to obey

$$\rho(j_1(s)) = \rho(s).$$

For later purposes, we introduce an $A$-Lie derivative $L_s$ along sections $s \in \Gamma(A)$ acting on sections of tensor powers of $A, A^*, TM$, and $T^*M$ in the following way: $L_s s' := [s, s']$, $L_s X := L_{\rho(s)} X \equiv [\rho(s), X]$ for all $s' \in \Gamma(A)$ and $X \in \Gamma(TM)$, extended by the Leibniz rule and the requirement to commute with contractions. Then in particular on $T^*M \otimes A$ one has

$$L_s (\omega' \otimes s') := L_{\rho(s)} (\omega') \otimes s' + \omega' \otimes [s, s'],$$

where $s, s' \in \Gamma(A)$ and $\omega' \in \Omega^1(M)$. It follows from (14), (16), and (17) that one has

$$[j_1(s), \omega' \otimes s'] = L_s (\omega' \otimes s').$$

The Lie algebroid structure on $T^*M \otimes A$ is induced by this; it is a bundle of Lie algebras since it belongs to the kernel of the anchor map and

$$[\omega \otimes s, \omega' \otimes s'] = \langle \omega, \rho(s') \rangle \omega' \otimes s - \langle \omega', \rho(s) \rangle \omega \otimes s'.$$

Note that in the case of the the standard Lie algebroid $TM$, the kernel in (13) becomes isomorphic to $\text{End}(TM)$ and the above formula Eq. (20) reduces merely to the commutator of endomorphisms.

\[\text{There is a choice of sign made here, which we find convenient to fix as follows for later purposes.}\]
The anchor map $\rho: A \to TM$ admits the first order prolongation $\rho^{(1)}: J^1(A) \to J^1(TM)$, commuting with the jet prolongation of sections, which makes \((21)\) commutative
\[
\begin{array}{c}
\Gamma(J^1(A)) \xrightarrow{\rho^{(1)}} \Gamma(J^1(TM)) \\
\downarrow j_1 \quad \quad \quad \downarrow j_1 \\
\Gamma(A) \xrightarrow{\rho} \Gamma(TM)
\end{array}
\]
and which is also a Lie algebroid morphism. Moreover, every Lie algebroid morphism $\varphi: (A_1, \rho_1) \to (A_2, \rho_2)$ of Lie algebroids over the same base and the base map being a diffeomorphism admits the first jet prolongation $\varphi^{(1)}: J^1(A_1) \to J^1(A_2)$, which is again a Lie algebroid morphism and which commutes with the prolongation of sections, such that the following diagrams are commutative:\(^8\)
\[
\begin{array}{c}
\Gamma(J^1(A_1)) \xrightarrow{\varphi^{(1)}} \Gamma(J^1(A_2)) \\
\downarrow j_1 \quad \quad \quad \downarrow j_1 \\
\Gamma(A_1) \xrightarrow{\varphi} \Gamma(A_2)
\end{array}
\quad
\begin{array}{c}
J^1(A_2) \xrightarrow{\rho_2^{(1)}} J^1(TM) \\
\downarrow \varphi^{(1)} \quad \quad \downarrow \text{Id} \\
J^1(A_1) \xrightarrow{\rho_1^{(1)}} J^1(TM)
\end{array}
\]

**Definition 1.** \((A, \nabla)\) is called a Cartan Lie algebroid over \(M\), if \(A\) is a Lie algebroid, \(\nabla\) a connection on \(A \to M\), and its induced splitting \(\sigma: A \to J^1(A)\) is a Lie algebroid morphism.

The compatibility of a Lie algebroid structure with a connection in the above sense is governed by the vanishing of the compatibility tensor $S$, the curvature of the splitting \((15)\), defined by the formula $S(s,s') = [\sigma(s), \sigma(s')] - \sigma([s,s'])$, where $s, s' \in \Gamma(A)$. Given that $\rho(S(s,s')) = 0$, it follows from \((13)\) for $E \sim A$ that $S$ can be identified with a section of $T^*M \otimes A \otimes \Lambda^2 A^*$. The next formula appears in \([2]\), Section 2.3 in a slightly different notation.

**Proposition 1.**
\[
S(s,s') = \mathcal{L}_s (\nabla s') - \mathcal{L}_{s'} (\nabla s) - \nabla_{\rho(\nabla s)} s' + \nabla_{\rho(\nabla s')} s - \nabla [s,s'].
\]

**Proof.** From \((15)\) we obtain
\[
S(s,s') = [j_1(s) + \nabla s, j_1(s') + \nabla s'] - j_1([s,s']) - \nabla [s,s'].
\]
Combining \((12)\) and \((18)\) we conclude that
\[
S(s,s') = \mathcal{L}_s (\nabla s') - \mathcal{L}_{s'} (\nabla s) + [\nabla s, \nabla s'] - \nabla [s,s'].
\]
We finally compute $[\nabla s, \nabla s']$ using \((20)\). This accomplishes our proof. $\square$

**Corollary 1.** Let $\{e_a\}$ be a local frame for $A$, such that $\rho(e_a) = \rho_a$ and $\nabla e_a = \omega^b_a e_b$, where $\rho_a$ and $\omega^a_b$ are local vector fields and 1-forms, respectively. Then
\[
S(e_a, e_b) = \left( L_{\rho_a} (\omega^b_c) - L_{\rho_b} (\omega^a_c) - (t_{\rho_a} \omega^c_b) \omega^a_e + (t_{\rho_b} \omega^c_a) \omega^b_e \right) e_c \\
+ \omega^a_a [e_a, e_a] - \omega^a_b [e_b, e_b] - \nabla [e_a, e_b].
\]
Proof. By Proposition 1 formula (23), we have
\[ S(e_a, e_b) = \mathcal{L}_{e_a} (\omega^b_c e_c) - \mathcal{L}_{e_b} (\omega^b_c e_c) - \omega^b_a \nabla_{\rho_b}(e_b) + \omega^b_a \nabla_{\rho_b}(e_a) - \nabla[e_a, e_b]. \]
From the explicit expression of the A-Lie derivative (18) we immediately obtain (24).

A section of \( A \) commutes with the corresponding anchor maps. An addition, this bundle map is a Lie algebroid morphism.

Given a vector bundle \( V \) on the first jet-prolongation of \( A \) with values in 1st order differential operators on \( V \), which obeys the condition
\[ A \nabla_s (f v) = \rho(s)(f)v + f A \nabla_s(v) \]
for every \( s \in \Gamma(A) \) and \( v \in \Gamma(V) \). The curvature of an A-connection is defined as
\[ A R(s, s') = [A \nabla_s, A \nabla_{s'}] - A \nabla_{[s, s']}, \]
where \( s, s' \in \Gamma(A) \). An A-connection is called flat if its A-curvature vanishes. A flat A-connection on \( V \) gives us a Lie algebroid representation of \( A \) on \( V \).

Given a vector bundle \( V \), the Atiyah algebroid of \( V \), denoted by \( L(V) \), is a bundle over \( M \), whose sections are infinitesimal automorphisms of \( V \); \( L(V) \) is a transitive Lie algebroid, the kernel of the anchor map of which coincides with the bundle of endomorphisms of \( V \). It is easy to verify that an A-connection on \( V \) is a vector bundle map \( A \rightarrow L(V) \) which commutes with the corresponding anchor maps. An A-connection is flat if and only if, in addition, this bundle map is a Lie algebroid morphism.

Definition 2. An A-connection on a vector bundle \( V \) is a \( C^\infty(M) \)-linear map \( A \nabla \) on sections of \( A \) with values in 1st order differential operators on \( V \), which obeys the condition
\[ A \nabla_s (f v) = \rho(s)(f)v + f A \nabla_s(v) \]
for every \( s \in \Gamma(A) \) and \( v \in \Gamma(V) \). The curvature of an A-connection is defined as
\[ A R(s, s') = [A \nabla_s, A \nabla_{s'}] - A \nabla_{[s, s']}, \]
where \( s, s' \in \Gamma(A) \). An A-connection is called flat if its A-curvature vanishes. A flat A-connection on \( V \) gives us a Lie algebroid representation of \( A \) on \( V \).

Definition 3. Given an A-connection \( A \nabla \) on the vector bundle \( A \) itself, the A-torsion of \( A \nabla \) is a section of \( \Lambda^2 A^* \otimes A \simeq \text{Hom}(\Lambda^2 A, A) \) defined at all \( s, s' \in \Gamma(A) \) according to
\[ A T(s, s') = A \nabla_s s' - A \nabla_{s'} s - [s, s']. \]
The dual A-connection \( A \nabla^* \) is determined at all \( s, s' \in \Gamma(A) \) by the formula
\[ A \nabla^*_s s' = [s, s'] + A \nabla_{s'} s. \]

Remark 1. An easy computation shows that the duality \( (A \nabla^*)_s = A \nabla \). From (27) and (28) it follows that the dual A-connection has the opposite A-torsion; thus, \( A \nabla \) coincides with its dual if and only if \( A T \) vanishes identically.

Let us observe that the Lie derivative of any tensor field \( \chi \) along a vector field \( X \) depends on the first jet-prolongation of \( X \) only, which allows us to introduce a natural Lie algebroid representation of \( J^1(TM) \) on arbitrary tensor fields, such that \( j_1(X) \) acts by the Lie derivative. The preceding observation, when looked at from a more general point of view, leads to the representation \( \alpha \) of \( J^1(A) \) on the tensor powers of \( A \) and \( A^* \) for any Lie algebroid \( A \), such that for all \( s \in \Gamma(A) \) one has on the one hand
\[ \alpha \circ j_1(s) = \mathcal{L}_s, \]
and on the other hand, as follows from (14), for all \( s, s' \in \Gamma(A), \omega \in \Omega^1(M) \)
\[ \alpha(\omega \otimes s)s' = (\omega, \rho(s'))s. \]
Correspondingly, \( \alpha(\omega \otimes s) \) acts by \( -\rho^*(\omega) \nabla s \) on \( \text{Sym}^*(A^*) \) and by \( -\rho^*(\omega) \wedge s \) on \( \Lambda^*(A^*) \).

Example 1. \( J^1(TM) \) is isomorphic to the Atiyah algebroid of \( TM \) by means of Eqs. (29) and (30). The Bott-sequence (13) specializes here to
\[ 0 \rightarrow \text{End}(TM) \rightarrow J^1(TM) \rightarrow TM \rightarrow 0. \]
Combining $\rho^{(1)}: J^1(A) \to J^1(TM)$ with the isomorphism from Example [1] we obtain a canonical representation $\tau$ of $J^1(A)$ on the tensor powers of $TM$ and $T^*M$, so that for all $s \in \Gamma(A)$, $X \in \Gamma(TM)$, $\omega \in \Omega^1(M)$ one has

$$\tau \circ j_1(s)X = [\rho(s), X], \quad \tau(\omega \otimes s)X = \langle \omega, X \rangle \rho(s).$$

Likewise, $\tau(\omega \otimes s)$ acts by $-\omega \wedge \tau(\rho(s))$ on $\text{Sym}^\bullet(TM^*)$ and by $-\omega \wedge \tau(\rho(s))$ on $\Lambda^\bullet(T^*M)$.

A more general statement is contained in the next proposition:

**Proposition 2.** Let $\mu$ be a representation of $J^1(A)$ on a vector bundle $V$ and let $\nabla$ be a connection on $A \to M$. If we identify $\nabla$ with a splitting $\sigma$ by [13], then the composition $\mu \circ \sigma$ gives us an $A$-connection on $V$, denoted by $\mu^\nabla$, which is flat if and only if the compatibility tensor $S$ obeys the condition $\mu \circ S(s, s') = 0$ for all $s, s' \in \Gamma(A)$. In particular, if $\nabla$ is a Cartan connection, so that $S \equiv 0$, then $\mu^\nabla$ is flat for every $\mu$. The representations (32) and (33), combined with a connection $\nabla$ on $A$, give us $A$-connections $\alpha \nabla$ and $\tau \nabla$ on $A$ and $TM$, respectively, such that for all $s, s' \in \Gamma(A)$, $X \in \Gamma(TM)$ one has

$$\alpha \nabla s s' = [s, s'] + \nabla_{\rho(s')}s$$

(33)

$$\tau \nabla s X = [\rho(s), X] + \rho(\nabla X s)$$

(34)

The anchor map $\rho: A \to TM$ obeys the property $\tau \nabla \circ \rho = \rho \circ \alpha \nabla$.

**Proof.** It follows from the definition of $\mu^\nabla$ and the compatibility tensor $S$ along with the explicit formulas (29) (30) for the representation $\alpha$, (32) for the representation $\tau$ and (15) for the splitting $\sigma$. We leave the details to the reader. □

A connection $\nabla$ induces another $A$-connection $A^\nabla = \nabla_{\rho(\cdot)}$, the $A$-torsion of which will be denoted by $A^\nabla$. From (33) we see that $A^\nabla$ is dual to $\alpha \nabla$. Denoting by $F \in \Gamma(A^2 T^* M \otimes A \otimes A^*)$ the curvature of $\nabla$, we obtain another expression for the compatibility tensor.

**Proposition 3.** Let $A$ be a Lie algebroid and $\nabla$ a connection on $A \to M$. Then the compatibility tensor $S$ admits the following expression:

$$S := \nabla (A^\nabla) + 2 \text{Alt}(\rho, F).$$

Here the anchor $\rho: A \to TM$ is viewed as a section of $A^* \otimes TM$, the contraction is taken by the natural pairing $TM \otimes A^2 T^* M \to T^* M$, $v \otimes \alpha \mapsto \alpha(v, \cdot)$, and the anti-symmetrization is taken over $A^* \otimes A^*$.

**Proof.** Our proof starts with the observation that for every $s, s' \in \Gamma(A)$ one has

$$\nabla (A^\nabla)(s, s') = \nabla (A^\nabla(s, s')) - A^\nabla(\nabla s, s') - A^\nabla(s, \nabla s').$$

The first term of the r.h.s. of the above formula reads as follows

$$\nabla (A^\nabla(s, s')) = \nabla (\nabla_{\rho(s)} s' - \nabla_{\rho(s')} s - [s, s']) = \nabla (\nabla_{\rho(s)} s') - \nabla (\nabla_{\rho(s')} s) - \nabla [s, s'],$$

while the second and the third terms can be expressed in the form

$$-A^\nabla(\nabla s, s') = -\nabla_{\rho(\nabla s)} s' + \nabla_{\rho(s')} (\nabla s) - \nabla_{\rho(\nabla s')} (\nabla s)$$

$$-A^\nabla(s, \nabla s') = \nabla_{\rho(\nabla s')} s - \nabla_{\rho(s)} (\nabla s') + \nabla_{\rho(\nabla s')} (\nabla s').$$

It is worth noting that $S$ has appeared in this form in [18].
Here the covariant derivative $\nabla$ is extended to differential forms with values in sections of $A$ by the Leibniz rule. Therefore, combining the above formulas and using (23), we get
\[
\nabla (A^T) (s, s') = S(s, s') + \nabla (\nabla_{\rho(s)} s') - \nabla (\nabla_{\rho(s)} s) - \nabla (\nabla_{\rho(s')} s) + \nabla (\nabla_{\rho(s')} s). 
\]

On the other hand, for every vector field $X$ and section $s$ one has
\[
\iota_X F(s) = \iota_X \nabla^2 s = (\iota_X \nabla + \nabla \iota_X) \nabla s - \nabla (\iota_X \nabla s) = \nabla_X (\nabla s) - \nabla (\nabla_X s).
\]

Finally we obtain
\[
\nabla (A^T) (s, s') = S(s, s') - \iota_{\rho(s)} F(s' + \iota_{\rho(s')} F(s)
\]
or, equivalently,
\[
S(s, s') = \nabla (A^T) (s, s') + \iota_{\rho(s)} F(s') - \iota_{\rho(s')} F(s).
\]
This accomplishes the proof. \(\square\)

**Corollary 2.** $(A, \nabla)$ is a Cartan Lie algebroid iff $S = 0$, i.e. iff $(A, \nabla)$ satisfies Eq. (11).\(^{10}\)

Let us specify the compatibility of a connection with a Lie algebroid structure for some typical cases.

**Example 2.** Let $A = M \times g$ be an action Lie algebroid. Then the canonical flat connection $\nabla$ is compatible. Furthermore, every flat Cartan Lie algebroid $(A, \nabla)$ is locally an action Lie algebroid; in fact, one even has:

**Proposition 4.** Let $(A, \nabla)$ be a flat Cartan Lie algebroid. Then every point $x \in M$ permits a neighborhood $x \ni U \subset M$ over which there exists an action Lie algebroid $C = U \times g_U$ such that $(A|_U, \nabla, g)$ and $(C, \nabla_{\text{canonical}}, g)$ are isomorphic as Cartan Lie algebroids. Moreover, within a connected component $M_i$ of $M$, the Lie algebra $g_U$ does not depend on the choice of $U$, $g_U \cong g_i$.

**Proof.** By Eq. (23) and Corollary 2 the Lie bracket of constant sections is constant as well; choosing a covariantly constant frame $e_a$ over some $U \ni x$, $\nabla e_a = 0$, the above mentioned property implies that $\text{d}(C^a_{bc}) = 0$. This proves the first part, i.e. the local isomorphism of Killing Lie algebroids $A|_U \cong U \times g_U$. For any other neighborhood $U'$ with constant frame $e'_a$ and non-trivial intersection $U \cap U' \neq \emptyset$, $(e_a)$ and $(e'_a)$ are related by an $\mathbb{R}$-linear basis change, which does not change the Lie algebra they generate. \(\square\)

**Example 3.** If $A$ is a bundle of Lie algebras, i.e. if $\rho \equiv 0$, then $\nabla$ on $A$ is compatible if and only if it preserves the fiber-wise Lie algebra bracket: $\nabla_X [\mu, \nu] = [\nabla_X \mu, \nu] + [\mu, \nabla_X \nu]$ for all $X \in \Gamma(TM)$ and $\mu, \nu \in \Gamma(A)$.

**Example 4.** If $A = TM$ is the standard Lie algebroid, a connection $\nabla$ on $TM$ is compatible if and only if its dual connection $\nabla^*$ is flat. So, $(TM, \nabla)$ being a Cartan Lie algebroid implies that $M$ is the quotient of a parallelizable manifold by a properly discontinuously acting discrete group. If, in addition, $\nabla$ is torsion-free, it is self-dual, $\nabla = \nabla^*$, and thus it needs to be flat itself.

**Example 5 (3).** Any torsion-free connection on $TM$ gives rise to a compatible (Cartan) connection on $J^1(TM)$.

\(^{10}\)We recall that $A^T = -A^T$. 
For what will come in the subsequent section, the following adaptations of Example \ref{example:1} will be of interest: Consider a manifold $M$ equipped with a Riemannian metric $g$. Denote by $L(g)$ the Lie subalgebroid of $J^1(TM)$ whose sections preserve $g$ by means of the representation of $J^1(TM)$ on tensors. Into the bargain, $L(g) \subset J^1(TM)$ is to be viewed as the differential equation whose solutions are Killing vector fields on $(M,g)$, that is, for any section $X \in \Gamma(TM)$, $j_1(X) \in L(g)$ if and only if $\mathcal{L}_X(g) = 0$. Even though a Riemannian manifold may not possess any Killing vector field, the algebroid $L(g)$ still exists. In this case only there are no first jet prolongations $j_1(X)$ that lands inside the subbundle $L(g) \subset J^1(TM)$.

$L(g)$ is naturally isomorphic to the Lie algebroid of infinitesimal bundle isometries of $(TM,g)$. Therefore, $L(g)$ is a transitive Lie algebroid, the kernel of the anchor map of which coincides with the bundle of skew-adjoint operators in $TM$, canonically identified with $\Lambda^2(T^*M)$ by use of the metric $g$, i.e. one has the following short exact sequence of Lie algebroids:

\begin{equation}
0 \rightarrow \Lambda^2(T^*M) \rightarrow L(g) \rightarrow TM \rightarrow 0.
\end{equation}

**Lemma 1.** The Levi-Civita connection $g_{\nabla}$ provides a splitting of \eqref{eq:1}. 

**Proof.** Let $\sigma_g$ be the splitting of the Bott exact sequence \eqref{eq:2}, determined by the Levi-Civita connection as in \eqref{eq:3}, then for all vector fields $X,Y,Z$ on $M$ one has

$$
\alpha \circ j_1(X)(g)(Y,Z) = (\mathcal{L}_Xg)(Y,Z) = \mathcal{L}_X(g(Y,Z)) - g([X,Y],Z) - g(Y,[X,Z]).
$$

Given that $g_{\nabla}$ is a torsion-free connection, $[X,Y] = g_{\nabla}XY - g_{\nabla}YX$, and since by formula \eqref{eq:4} being applied to the standard Lie algebroid $-\alpha(g_{\nabla}X)(g)(Y,Z) = g(g_{\nabla}X,Y, Z) + g(Y, g_{\nabla}ZX)$, we obtain

$$
\alpha \circ j_1(X)(g)(Y,Z) = g_{\nabla}X(g)(Y,Z) - \alpha(g_{\nabla}X)(g)(Y,Z).
$$

On the other hand, $g_{\nabla}(g) = 0$, thus

$$
\alpha \circ \sigma_g(X)(g) = \alpha(j_1(X) + g_{\nabla}X)(g) = 0.
$$

Hence it follows that $\sigma_g$ takes values in $L(g)$, which is the desired conclusion. \hfill \Box 

4. Lie algebroids over Riemannian manifolds

**Definition 4.** Let $(A, \rho, [\cdot, \cdot])$ be a Lie algebroid over a Riemannian manifold $(M,g)$ and $\nabla$ a connection on $A$. Then $(A, \nabla)$ and $(M,g)$ are called compatible, if

\begin{equation}
\tau_{\nabla}(g) = 0,
\end{equation}

where the $A$-connection $\tau_{\nabla}$ is defined as in Eq. \eqref{eq:5}. We call the triple $(A, \nabla, g)$ a Killing Lie algebroid, and, if in addition, also $A$ and $\nabla$ are compatible in the sense of Definition \ref{definition:4} (cf. also Corollary \ref{corollary:2}), a Killing Cartan Lie algebroid.

**Remark 2.** Eqs. \eqref{eq:5} and \eqref{eq:6} are meaningful also for merely anchored bundles:

**Definition 5.** $(E, \rho)$ is called an anchored bundle over $M$, if $E \rightarrow M$ is a vector bundle and $\rho: E \rightarrow TM$ a vector bundle morphism. We call $(E, \rho, g)$ a Killing anchored bundle if Eq. \eqref{eq:6} holds true.
In some cases of what will follow in this and the subsequent section, we will assume the bundle to carry a Lie algebroid structure, although sometimes weaker conditions are sufficient for the statement. On the other hand, we will not require the compatibility of this Lie algebroid structure with the connection except if otherwise stated. One option for a passage from a Killing anchored bundle to a Killing Cartan Lie algebroid is explained in the final section, Sec. 6.

**Lemma 2.** By means of $g$, we can view the anchor $\rho \in \Gamma(A^* \otimes TM)$ as a section of $A^* \otimes T^*M$, which we denote by $\bar{\rho}$. The connection on $A$ and the Levi-Civita connection on $TM$ induce a connection on $A^* \otimes T^*M$, which we also denote simply by $\nabla$. Then Eq. (37) holds true if and only if

$$\text{Sym}(\nabla \bar{\rho}) = 0.$$  

**Proof.** One may verify this either by a direct calculation or proceed by the more conceptual consideration that follows: Using the canonical isomorphism between skew-symmetric bilinear forms and skew-adjoint operators by means of the Riemannian metric $g$, we deduce that Eq. (38) is satisfied if and only if $\nabla \rho(s) = \rho(\nabla s)$ is a skew-adjoint operator in $TM$ for any $s \in \Gamma(A)$ and, consequently, is a section of $L(g)$. From [15] and (21) we have

$$\sigma_g \circ \rho(s) - \rho(1) \circ \sigma(s) = g \nabla \rho(s) - \rho(\nabla s)$$

since $\rho(1)(\nabla s) = \rho(\nabla s)$, where $\rho$ is extended to act on sections of $T^*M \otimes A$ as $\text{id} \otimes \rho$. Thus the l.h.s. of Eq. (39) is also a section of $L(g)$. By Lemma 1, the image of $\sigma_g$ is contained in $L(g)$, therefore Eq. (38) is seen to be equivalent to the requirement $\rho(1) \circ \sigma : A \to L(g)$, which in turn is equivalent to $\nabla$ annihilating the metric $g$; the latter fact follows from the construction of $\nabla$ and $L(g)$. $\square$

**Lemma 3.** Suppose there exists a section $s \in \Gamma(A)$ which is covariantly constant, $\nabla s = 0$. Then $v := \rho(s)$, provided non-zero, is a Killing vector field of the metric $g$, $\mathcal{L}_v g = 0$.

**Proof.** Clearly, Eq. (38) implies $\text{Sym}(\nabla \bar{v}) = 0$ where $\bar{v} \equiv (s, \bar{\rho}) \in \Gamma(T^*M)$. Rewriting this in terms of $v$, $\bar{v} = g(v, \cdot)$, this equation is known to become $\mathcal{L}_v g = 0$. $\square$

**Remark 3.** Using notations from Corollary 1, we can rewrite (37) as

$$\mathcal{L}_{\rho(s)} g - \omega_a^k \nabla \tau_{\rho(s)} g = 0$$

for all $a = 1, \ldots, \text{rk} A$; this expression coincides with the original form of the extended Killing equations found in [15]. This fact, as well as the observation in the previous Lemma, led us to use the term “Killing Lie algebroid”. While this nomenclature reflects well the relation to symmetries of the geometric structure on the base here, its generalization to other appropriately compatible geometric structures on the base (cf. the subsequent section) is not obvious (for example if the Killing vectors are replaced by symplectic ones).

Since equations such as (40) are of the form how they appear in the context of their original appearance, and henceforth we will turn to a reformulation such as in Eq. (37), using the $A$-connection $\nabla$ also in more general context, we consider it illustrative to show equivalence of these two formulations by an explicit calculation:

**Proof (equivalence of (37) with the local expression (40)).** Let $X \in \Gamma(TM)$ be a vector field on $M$ and $s$ a section in $A$. $\nabla_s g$ acting on the function $g(X, X)$ agrees, by definition of an $A$-Lie derivative, with $\mathcal{L}_{\rho(s)}$ acting on it. On the other hand, evidently we have...
\[\tau \nabla_s (g(X, X)) = (\tau \nabla_s g)(X, X) + 2g(\tau \nabla_s X, X).\] Since by the defining equation 13, \(\tau \nabla_s X = L_{\rho(s)} X + \rho(\nabla_X s),\) we obtain \((\tau \nabla_s g)(X, X) = (L_{\rho(s)} g)(X, X) - 2g(\rho(\nabla_X s), X).\) Using \(\rho(\nabla_X e_a) = (\iota_X \omega^h_b) \rho(e_a)\) for any local frame \(e_a\) in \(A\) then yields Eq. 10. □

**Example 6.** Let \(g\) be the isometry Lie algebra of a metric \(g\) on \(M.\) Then the action Lie algebroid \(M \times g,\) its canonical flat connection, together with \(g\) form a Killing Cartan Lie algebroid. Furthermore, as remarked in Example 2 and Proposition 4, every flat Cartan Lie algebroid \((A, \nabla)\) is locally an action Lie algebroid, \((A|_U, \nabla) \cong (U \times g, \nabla_{\text{canonical}}),\) where the Lie algebra \(g\) is the same for any connected component \(M_i\) of \(M.\) Adding the prefix “Killing” then implies that now the image \(h_i\) of \(g\) by the anchor map \(\rho,\) a morphism of Lie brackets, is necessarily a sub-Lie algebra of the local isometry Lie algebra \(iso\) of \((M_i, g): \rho(h_i) = h_i \subset iso_i.\) The Lie algebras \(g_i\) of the local action Lie algebroids are thus extensions of local isometry Lie algebras: \(0 \to \ker(\rho) \to g_i \xrightarrow{\rho} h_i \to 0\) in this case.

**Example 7.** The standard Lie algebroid \(TM\) of a Riemannian manifold \((M, g)\) is a Killing Lie algebroid with respect to any metrical connection \(\nabla\) (e.g. \(w.r.t.\) the Levi-Civita connection \(\nabla\)). Indeed, in this case \(\rho = g\) and Equation 18 holds true even without the symmetrization. \((TM, g, \nabla)\) is a Killing Cartan Lie algebroid iff \(g\) is a flat metric, i.e. iff \(R \nabla = 0.\) \((TM, \nabla, g)\) is a Killing Cartan Lie algebroid iff \(\nabla\) is metrical and its curvature \(R\) and torsion \(T\) satisfy the equation \(T_{jkl}^i = R_{jkl}^i - R_{kjl}^i,\) written for clarity in index notation, the semi-colon denoting the covariant derivative.

**Example 8** (15). A characteristic example results from (regular) foliations \(F\) of a manifold \(M\) with a smooth quotient \(Q = M/F.\) There exists a connection \(\nabla\) on \(A = TF\) such that \((TF, \nabla, g)\) forms a Killing Lie algebroid, iff \((M, F, g)\) provides a Riemannian submersion, i.e. iff \(Q\) is equipped with a metric \(g_Q\) such that for any point \(p \in M\) the natural projection \(T_p F \supset \to T_p|_p Q\) is an isometry.

While on the one hand Killing Lie algebroids (and their generalizations to other geometric structures) encompass symmetries in terms of a connection such that locally flat sections (with non-trivial image \(\text{w.r.t.}\) the anchor) reproduce infinitesimal, local symmetries, on the other hand, even in the absence of symmetries, if the leaf space \(Q := M/F\) is smooth, the conditions ensure that there is some kind of quotient construction (of the same kind in the Riemannian case, i.e. \((Q, g_Q)\) is the quotient of \((M, g)\) by the foliation \(F).\) This aspect is in its spirit closely related to the gauge theories where the notion arose from, cf. 15 as well as the Introduction; and in both cases, the geometrical as well as the gauge theoretical context, the notion becomes particularly interesting when there is no smooth quotient, providing a smooth description of it. Evidently, the connection contains information about the metric on the leaves of the foliation factored out in the previous example, cf., e.g., Eq. 10. It permits a partial reconstruction of the metric on the total space. More precisely, formulated for a regular foliation with smooth quotient, this looks as follows:

**Proposition 5.** Let \(\pi: M \to Q\) be a bundle over a Riemannian manifold \((Q, g_Q)\) with connected fibers, let \(\nabla_M\) be an Ehresmann connection on \(\pi,\) i.e. a splitting \(T_x M = H_x \oplus V_x\) with \(V_x \cong T_x F,\) and \(\sigma \in \Gamma(\pi)\) a section such that for all \(x\) in its image, \(x \in \sigma(Q),\) one is given a smoothly varying metric \(g_x\) on the vertical subspace \(V_x.\) Denote by \(T_F \subset TM\) the foliation Lie algebroid over \(M\) corresponding to \(\pi.\) For every choice of a \(T_F-\text{connection}\)
(a connection along the fibers) $\nabla_X \nabla$ on $T\mathcal{F}$, the holonomy of which at $T\mathcal{F}|_{\sigma(Q)}$ preserves the metric $\eta$, there is a unique connection $\nabla$ on $T\mathcal{F}$ and a unique metric $g$ on $M$, such that $(T\mathcal{F}, \nabla, g)$ is a Killing Lie algebroid, $H_x$ is orthogonal to $V_x$ w.r.t. $g_x$ for all $x \in M$, the restriction of $g_x$ on $V_{\sigma(q)}$ agrees with $\eta_{\sigma(q)}$ for each $q \in Q$, and the restriction of $\nabla$ on fibers coincides with $\nabla \nabla^*$, the dual $T\mathcal{F}$-connection defined by Eq. (28).

**Proof.** The connection $\nabla$ is defined by the requirement that $\nabla_X (s') = [X, s']^V$, $\nabla_s s' = \nabla \nabla^* s'$ for every $X \in \Gamma(H)$ and $s, s' \in \Gamma(T\mathcal{F})$, where $[-,-]^V$ is the vertical component of the corresponding Lie bracket. Use Eq. (37) and the holonomy property, noting that $\nabla$ is a partially defined covariant derivative, permitting one to transport $\eta_{\sigma(q)}$ to the metric $g|_{T\mathcal{F}}$. By Eq. (34), for every connection $\nabla'$ on $T\mathcal{F} \to M$, the vertical subbundle $\mathcal{T}\mathcal{F}$ is $\nabla'$-invariant. Moreover, the induced connection $\nabla'/T\mathcal{F}$ on the normal bundle $TM/T\mathcal{F}$ gives rise to the canonical normal transversal action of $T\mathcal{F}$, thus it is flat and it does not depend on the choice of $\nabla'$. On the other hand, by the construction of $\nabla$, both subbundles $H$ and $V = T\mathcal{F}$ are $\nabla$-invariant, so that $(H, \nabla|_H)$ is canonically isomorphic to the transversal representation of $T\mathcal{F}$. This allows us to define a unique $\nabla$-invariant metric on $H$, such that $\pi_\sigma : H_x \to T_{\sigma(x)}Q$ is an isometry for all $x \in M$. The metrics on $H$ and $T\mathcal{F}$ determine a unique metric on $M$, such that $H$ is orthogonal to $V$ (and thus $\pi : M \to Q$ is a Riemannian submersion). Since the obtained metric on $M$ is $\nabla$-invariant, $(T\mathcal{F}, \nabla, g)$ is a Killing Lie algebroid. □

**Example 9.** That one may encounter simple obstructions in the search for further examples of Killing Lie or even Killing anchored algebroids is illustrated by the following:

**Proposition 6.** Let $E = \mathbb{R}^2 \times \mathbb{R}$ with $\rho(x, y, u) = u x^n \frac{\partial}{\partial x}$ for some $n \in \mathbb{N}$. There exists no connection $\nabla$ on $E$ and metric $g$ on $M = \mathbb{R}^2$ such that $(E, g, \rho)$ forms a Killing anchored algebroid.

**Remark 4.** Note that every anchored line bundle $L \to M$ is compatible with one and only one Lie algebroid structure, i.e. the anchor $\rho : L \to TM$ determines the Lie algebroid structure already completely and there exists one for every choice of the map $\rho$. Indeed, consider a local chart $U \subset M$ over which $L|_U \cong U \times \mathbb{R}$. The unit section 1 of this trivial bundle is mapped to a vector field $v = \rho(1) \in \Gamma(TU)$. Any other local section $s \in \Gamma(L|_U)$ then satisfies $s = f \cdot 1$ for some $f \in C^\infty(U)$. For two such sections $s, s'$, the bracket takes necessarily the form: $[s, s'] = (f v(f') - f' v(f)) \cdot 1$. Since, on the other hand, one verifies that this satisfies all axioms of a Lie algebroid over $U$, and that the bracket is equivariant with respect to a change of basis over $U$, one may extend it also to all of $M$ by a partition of unity; this also proves existence.

**Proof (of Proposition 4).** For the constant section $s = 1$ with $v := \rho(1) = x^n \frac{\partial}{\partial x}$ and $\nabla(1) = \omega \otimes 1$, Equation (1) becomes

$$\tag{41} \mathcal{L}_v g = \omega \wedge \iota_v g ,$$

where $\omega \wedge \iota_v g \equiv \omega \otimes \iota_v g + \iota_v g \otimes \omega$. Comparing the components of $dx \otimes dx$ on both sides for the given vector field $v$, yields the equation

$$x^n \frac{\partial}{\partial x}(g_{xx}) + 2 g_{xx} x^{n-1} = 2 \omega x g_{xx} x^n$$
or, since \( g_{xx} > 0 \), equivalently
\[
n = x \left( \omega_x - \frac{1}{2} \partial_x \ln(g_{xx}) \right).
\]

For whatever the choice of \( g \) and \( \omega \), i.e. \( \nabla \), this last equation yields a contradiction upon evaluation at \( x = 0 \). \qed

All the more it is important to provide further, non-trivial examples of Killing Lie algebroids. That a very large class of them exists follows from the following theorem.

**Theorem 1.** Any Lie algebroid \( A \) which is integrable to a proper Lie groupoid permits a metric \( g \) and a connection \( \nabla \) to turn \( (A, \nabla, g) \) into a Killing Lie algebroid.

This Theorem is corollary of the result of M. de Hoyo and R. Fernandes \[8\], which states that any proper Lie groupoid admits what they call a 2-metric, as well as Lemma 4 and Lemma 5 below; the second of those lemmas asserts that the Lie algebroid of any Lie groupoid with 1-metric admits a canonical Killing Lie algebroid structure.\[11\

Let \( \pi : (\tilde{M}, \tilde{g}) \to (M, g) \) be a Riemannian submersion. Denote by \( V(\pi) \) the subbundle of \( \pi \)-vertical vectors and by \( H \) its orthogonal complement with respect to \( \tilde{g} \), such that every vector field \( \tilde{X} \) on \( \tilde{M} \) admits the canonical decomposition into the horizontal and vertical parts, \( \tilde{X}_H \) and \( \tilde{X}_V \), respectively. Denote by \( X^h \) the unique horizontal lift of a base vector field \( X \), such that \( d\pi(X^h) = X \). The following 3-tensor field \( O \), introduced by O’Neill in \[21\]\[12\] associates to a pair of vector fields \( \tilde{X}, \tilde{Y} \) on \( \tilde{M} \) a vector field \( O_{\tilde{X}}\tilde{Y} \), where, by definition,
\[
O_{\tilde{X}}\tilde{Y} = \left( \tilde{g} \nabla_{\tilde{X}_H} \tilde{Y}_H \right)_V + \left( \tilde{g} \nabla_{\tilde{X}_H} \tilde{Y}_V \right)_H.
\]

**Lemma 4** (O’Neill, \[21\]).
1. At each point, \( O_{\tilde{X}} \) is a skew-symmetric linear operator on the tangent space of \( \tilde{M} \) interchanging the horizontal and vertical subspace.
2. If \( \tilde{X} \) and \( \tilde{Y} \) are horizontal vector fields on \( \tilde{M} \), then \( O_{\tilde{X}}\tilde{Y} = \frac{1}{2} [\tilde{X}, \tilde{Y}]_V \).
3. For \( H \)-horizontal lifts \( X^h, Y^h \) of basic vector fields \( X, Y : (\tilde{g} \nabla_{X^h} Y^h)_H = (\tilde{g} \nabla_{X^h} Z^h)_H \).

**Corollary 3.** If \( \tilde{X}, \tilde{Y} \) are horizontal vector fields on \( \tilde{M} \) and \( \xi \) a vertical vector field, then \( \tilde{g} \tilde{g} (\tilde{g} \nabla_{\tilde{X}} \tilde{Y}^h, \xi) \), which is evidently equal to \( -\tilde{g} \tilde{g} (\tilde{g} \nabla_{\tilde{X}} \xi, \tilde{Y}) \), is skew-symmetric with respect to \( \tilde{X} \) and \( \tilde{Y} \). If \( X^h, Y^h, \) and \( Z^h \) are \( H \)-horizontal lifts of vector fields \( X, Y, \) and \( Z \) on \( M \), respectively, then
\[
\tilde{g} \tilde{g} (\tilde{g} \nabla_{X^h} Y^h, Z^h) = \tilde{g} \tilde{g} (\tilde{g} \nabla_{X^h} Y^h, Z^h).
\]

Finally, for \( X, Y \) vector fields on \( M \) and \( X^h, \tilde{Y} \) vector fields on \( \tilde{M} \), such that \( X^h \) is the horizontal lift of \( X \) and \( \tilde{Y} \) is any \( \pi \)-projectible lift of \( Y \), i.e. a vector field on \( \tilde{M} \) such that \( d\pi(\tilde{Y}) = Y \), one has
\[
\tilde{g} \tilde{g} (\tilde{g} \nabla_{X^h} \tilde{Y}^h, X^h) = \tilde{g} \tilde{g} (\tilde{g} \nabla_{X^h} \tilde{Y}^h, X^h).
\]

\[11\] The latter fact was found first by Camille Laurent-Gengoux and Sylvain Lavau (communicating it to us without showing us their proof).

\[12\] In \[21\], this tensor was called \( A \); we refrained from this notation here, since \( A \) already denotes the Lie algebroid throughout this paper.
Proof. To see the skew-symmetry, use the defining equation for the O’Neill’s tensor $O$, Eq. (42), and the second item in O’Neill’s Lemma 4. Similarly, Eq. (43) follows from the third part of the Lemma and the definition of a Riemannian submersion. The final equation, Eq. (44), then results from Eq. (43) and the before-mentioned skew-symmetry. □

Lemma 5. Let $\mathcal{G}$ be a Lie groupoid over $M$ with the source map $s$, target map $t$, and the identity bisection $e$. Assume that $\mathcal{G}$ is endowed with a Riemannian metric $\eta$, such that both $s$ and $t$ are Riemannian submersions $s: (\mathcal{G}, \eta) \rightarrow (M, g)$ and $t: (\mathcal{G}, \eta) \rightarrow (M, g')$ for some metrics $g$ and $g'$ on $M$, respectively. Then the Lie algebroid $A$ of $\mathcal{G}$, identified with left invariant $t$-vertical vector fields on $\mathcal{G}$, is a Killing Lie algebroid over $(M, g)$.

Proof. Let $\xi$ be a section of $A$, identified with the corresponding vector field on $\mathcal{G}$, such that $\rho(\xi) = ds(\xi)$, $X$ be a vector field on $M$, and $X^h$ be the horizontal $s$-lift of $X$, orthogonal to the $s$-fibers. From (44) we obtain

$$
\eta\left(\lvert^h\nabla_{X^h}\xi, X^h\right) = g\left(\lvert^h\nabla_X\rho(\xi), X\right).
$$

Consider now the following symmetric 2-form $C(\tilde{X}, \tilde{Y}) = \eta(\lvert^h\nabla_{\tilde{X}}\xi, \tilde{Y})$ on $\mathcal{G}$. Using metric $\eta$, we identify $C$ with a section of $T\mathcal{G} \otimes T\mathcal{G}$; the latter decomposes into the direct sum of orthogonal components according to the orthogonal decomposition $T\mathcal{G} = V(t) \oplus V(t)^\perp$, where $V(t) = \text{Ker}\, dt$. By the the first part of Corollary 3 being applied to the Riemannian submersion $t$, we get that $C = C_0 + C_1 + C_2$, where $C_0$, $C_1$ and $C_2$ are sections of $\Lambda^2 V(t)^\perp$, $T\mathcal{G} \otimes V(t)$, and $V(t) \otimes V(t)^\perp$, respectively. Obviously, $C_1(\tilde{X}, \tilde{Y}) = \eta(\lvert^{pr}\nabla_{\tilde{X}}\xi, \tilde{Y})$, where $\lvert^{pr}$ is the orthogonal projection of the Levi-Civita connection onto sections of $V(t)$. Besides, there exists a unique section $\psi^{pr}$ of the bundle of endomorphisms $TG \rightarrow \text{End}(V(t))$, which factors through the orthogonal projection onto $V(t)^\perp$, such that $C_2(\tilde{X}, \tilde{Y}) = \eta(\tilde{X}, \psi^{pr}_{\tilde{Y}}\xi)$. Since $C_0$ is a skew-symmetric 2-form, we conclude that

$$
C(\tilde{X}, \tilde{X}) = \eta(\nabla^{tot}_{\tilde{X}}\xi, \tilde{X}),
$$

where $\nabla^{tot} = \lvert^{pr} + \psi^{pr}$. Now (45) reads as follows:

$$
g\left(\lvert^h\nabla_X\rho(\xi), X\right) = \eta\left(\nabla^{tot}_{\tilde{X}}\xi, X^h\right).
$$

Given that the l.h.s. of (46) is constant along $s$-fibers, we can evaluate the r.h.s. at the identity bisection $e$. Thus

$$
g\left(\lvert^h\nabla_X\rho(\xi), X\right) = \eta\left(\left(\nabla^{tot}_{X^h}\xi\right)|_{e}, X^h|_{e}\right) = g\left(\rho \circ \nabla_X\xi, X\right),
$$

where $\nabla_X$ is defined on sections of $A$ as the composition of $\nabla^{tot}_{X^h}$ and the evaluation at the identity bisection $e$. In this way, we have obtained a connection on $A$ such that the identity (38) holds. This concludes the proof of Lemma 5 and, at the same time, of Theorem 4. □

Remark 5. Note that Theorem 4 does not give any information about an eventual compatibility of the Lie algebroid structure on $A$ with the connection $\nabla$. On the other hand, using averaging methods by fiber-integration developed on proper groupoids, the Theorem does not only have an existence part, it also permits one to construct non-trivial examples of Killing Lie algebroids. We intend to come back to such examples elsewhere.

---

13The base metrics $g$ and $g'$ do not need to coincide. This condition is weaker than a 1–metric on $\mathcal{G}$ in the original notations from [8], where $g$ and $g'$ must coincide. Thus we essentially prove a stronger statement. A proper Lie groupoid admits even a 2-metric which contains far more information than what we need for the existence of a Killing Lie structure: we shall develop this subject in the next paper.
We now turn to some properties one may show to hold for Killing Lie algebroids. For example, we claimed before that Example 8 is in some sense characteristic, although the regular foliation and the smooth quotient seem very restrictive for a Lie algebroid. A generalization of Riemannian submersions to the non-smooth setting and for also singular foliations is given by Riemannian foliations [20]. It is thus comforting to find

**Proposition 7.** The base $M$ of any Killing Lie algebroid $(A, \nabla, g)$ carries a canonical (possibly singular) Riemannian foliation. (The leaves are generated by the Lie algebroid structure $A$ and the leaf-wise metric is induced by $g$).

**Proof.** Let $p$ be a point of $M$ and let $\gamma$ be a geodesic curve with the natural parameter $s \in [0, 1]$ such that $\dot{\gamma}(0) \in (T_p F)^\perp$, where $\dot{\gamma}$ is the derivation along $s$. Consider the pullback bundles $\gamma^*(A)$ and $\gamma^*TM$ together with the corresponding pullback connections and the pullback of the anchor map regarded as a bundle morphism $\rho: \gamma^*A \to \gamma^*TM$. Given that $\gamma$ is a 1-dimensional manifold, the pullback connection is flat, thus we can choose a flat trivialization $\{e_a\}$ of $\gamma^*(A)$ in some neighborhood of $p \in \gamma$. Now we have:

$$\partial_s g(\dot{\gamma}, \rho(e_a)) = g(\nabla_{\dot{\gamma}} \dot{\gamma}, \rho(e_a)) + g(\dot{\gamma}, \nabla_{\dot{\gamma}} \rho(e_a)).$$

The first term of (47) is identically zero since $\gamma$ is a geodesic curve, while the second term vanishes because of the extended Killing equation, Eq. (58) being applied to the flat frame $\{e_a\}$. Indeed, $\nabla_{\dot{\gamma}} \rho(e_a) = (\nabla_{\dot{\gamma}} \rho)(e_a)$ and thus $g(\dot{\gamma}, \nabla_{\dot{\gamma}} \rho(e_a)) = \text{Sym}((\nabla \rho)(e_a))(\dot{\gamma}, \dot{\gamma}) = 0$. Therefore $g(\dot{\gamma}, \rho(e_a))$ does not depend on $s$, thus it must be zero as $\dot{\gamma}(0) \in (T_p F)^\perp$. This proves that the geodesic remains orthogonal to the foliation for all $s$, which is a possible characterization of a Riemannian foliation, cf. [20]. □

Let us for the rest of the section consider a fixed Riemannian base $(M, g)$ and determine some conditions under which this can be the base of a Killing Lie algebroid. Remember that the Lie algebroid $L(g)$, fitting into the sequence (26), exists for any metric $g$. We will use below the germ version of the pre-image of a vector sub-bundle by a bundle map: namely, given a vector bundle map $\phi: V \to W$ between two vector bundles over $M$ and a vector subbundle $W' \subset W$, we define $\phi^{-1}(W')$ at $x \in M$ as the set of vectors $v \in V_x$ which admit prolongations to local sections of $V$ with the image in $W'$.

**Proposition 8.** Let $(A, \rho, [\cdot, \cdot])$ be a Lie algebroid over a Riemannian manifold $(M, g)$. Then $A$ admits a connection which satisfies the equation (77), if and only if the preimage of $L(g)$ by $\rho^{(1)}$ is surjective over $A$. The choice of such a compatible connection $\nabla$ is in one-to-one correspondence with the choice of a splitting of $(\rho^{(1)})^{-1}(L(g))) \to A$.

**Proof.** By the above (germ) definition, the pre-image of $L(g)$ by $\rho^{(1)}$ is surjective over $A$ if and only if for any point $x$ in $M$ there exists an open neighborhood $U$ of $x$ and a local connection on $A|_U$, the restriction of $A$ to $U$, which is compatible with $g$. Let us choose an open cover of $M$ together with a local connection on $A$ over each open subset from the cover, which is compatible with $g$. Using a partition of unity subordinated to the chosen open cover and taking the corresponding linear combination of the local connections, we construct a global connection on $A$ compatible with $g$ on $M$. □

Given existence of the Killing Lie algebroid $(A, \nabla)$ over $(M, g)$, one may ask for the ambiguity in the choice for $\nabla$. Let us for this purpose consider the following Koszul complex of vector bundles: $\tilde{C}^q := \text{Sym}T^*M \otimes \Lambda^q A$, $q = 0, \ldots, \text{rk} A$, with the differential
\( \tilde{\delta} \) obtained by the natural extension of \( \tilde{\rho} \), where the latter is regarded as a section of \( A^* \otimes T^* M \simeq \text{Hom}(A, T^* M) \). More precisely, \( \tilde{\delta} \) acts on \( \Lambda \Lambda^1 A \) by contraction with the first factor of \( \tilde{\rho} \) and on \( \text{Sym}^2 T^* M \) by symmetric multiplication on the second one. Now we take the twisted complex \( C^* = \tilde{C}^* \otimes A^* \) with the differential \( \delta = \tilde{\delta} \otimes \text{id} \). This complex is graded by sub-complexes \( C^*_k = \bigoplus_{p+q=k} \text{Sym}^p T^* M \otimes \Lambda^q A \otimes A^*, \kappa = 0, \ldots, \dim M + \text{rk} A \).

Let \( C^q_k := \Gamma (C^q_k) \) with the induced differential \( \delta: C^q_k \to C^{q-1}_k \) (we identify the bundle map \( \delta \) with the underlying operator acting on sections).

**Proposition 9.** Let \( (A, \nabla, g) \) be a Killing Lie algebroid. Then \( \nabla + \psi \) for some \( \psi \in \Gamma (T^* M \otimes \text{End} A) \) defines another connection compatible with \( g \), if and only if \( \delta(\psi) = 0 \).

**Proof.** Since \( \text{Sym}(\nabla \tilde{\rho}) = 0 \), the equation \( (38) \) for \( \nabla + \psi \) implies that

\[
\text{Sym} \otimes \text{id} ( (\text{id} \otimes \tilde{\rho} \otimes \text{id})(\psi)) = 0,
\]

where \( \tilde{\rho} \) is regarded as a section of \( \text{Hom}(A, T^* M) \) and \( \psi \) as a section of \( T^* M \otimes A \otimes A^* \), so that \( \tilde{\rho} \) is applied to the second factor of \( \psi \). Let us think of \( \psi \) as an element of \( C^2_2 \). By the definition of the Koszul differential \( \delta \) the following diagram is commutative

\[
\begin{array}{ccc}
TM^* \otimes A \otimes A^* & \xrightarrow{\text{id} \otimes \tilde{\rho} \otimes \text{id}} & T^* M \otimes T^* M \otimes A^* \\
\downarrow{\delta} & & \downarrow{\text{Sym} \otimes \text{id}} \\
\text{Sym}^2 T^* M \otimes A^*
\end{array}
\]

This proves the proposition. \( \square \)

We finally return to the aspect of the relation of Killing Lie algebroids to Killing vectors. It is well-known that the space of Killing vectors on an \( n \)-dimensional, connected manifold \( M \) is a vector space of dimension at most \( n(n+1)/2 \). There is a straightforward generalization of this fact: Starting from Eq. \( (38) \), one derives an equation expressing the two-fold covariant derivatives of \( \tilde{\rho} \equiv t^g g \) in terms of itself and its first covariant derivative in the standard way; the only difference now is that the curvature appearing in this equation now is the total curvature \( F_\nabla + R_\nabla \). Since in this context we never refer to the Lie algebroid structure on the bundle, one obtains a statement for Killing anchored bundles:

**Proposition 10.** Let \( E \) be a rank \( r \) vector bundle over an \( n \)-dimensional, connected Riemannian manifold \( (M, g) \) and \( \nabla \) a connection on \( E \). Denote by \( V_g \) the vector space of Killing vector fields on \( (M, g) \). Then the following facts hold true: Anchors \( \rho \in \Gamma (A^* \otimes TM) \) satisfying \( (2) \) form a finite-dimensional vector space \( W \), whose dimension is bounded by \( \dim W \leq \frac{r \cdot n(n+1)}{2} \). For a metric \( g \) of constant curvature and \( A = M \times \mathbb{R}^r \) with its natural flat connection, \( W \cong (V_g)^\otimes r \), attaining the above bound. In general, the dimension of \( W \) can be greater than \( r \) times the dimension of \( V_g \).

The last sentence is proven, e.g., by Example \( \Box \) with \( M = Q \times \mathcal{F} \) for a metric \( g = g_Q + g_F \) with no isometries: \( \dim V_g = 0 \) and \( \dim W \geq 1 \).

While flat Killing Cartan Lie algebroids are locally action Lie algebroids with \( \rho \) being a (Cartan) Lie algebroid morphism into \( M \times \text{iso}(g) \), where \( \text{iso}(g) \) denotes the isometry Lie algebra of the metric \( g \), cf. Example \( \Box \) the relation of the more general flat Killing Lie algebroids to isometries of \( g \) is more intricate. We defer some further aspects of flat Killing Lie algebroids, Cartan and not Cartan, to Appendix A.
5. Lie algebroids over manifolds with other geometric structures

Definition 6. Let \((A, \rho, [\cdot, \cdot])\) be a Lie algebroid over \((M, \Phi)\), where \(\Phi \in \Gamma(T^*M \otimes T^*M)\) is a non-degenerate bilinear form on \(M\), \(\nabla\) be a connection on \(A\), and \(\psi\) a section of \(T^*M \otimes \text{End}(A)\). Then \((A, \nabla, \psi)\) and \((M, \Phi)\) are called compatible, if

\[
\tau \nabla^\text{comb}(\Phi) = 0,
\]

where \(\tau \nabla^\text{comb} = \tau \nabla^+ \otimes \text{Id} + \text{Id} \otimes \tau \nabla^-\) corresponding to \(\nabla^\pm = \nabla \pm \psi\) and \(\tau \nabla\) corresponding to a connection \(\nabla\) was defined in Eq. (44).

Remark 6. Since the difference of any two connections on a bundle \(A\) is a section in \(T^*M \otimes \text{End}(A)\), one may consider \(\nabla^+ =: \nabla^1\) and \(\nabla^- =: \nabla^2\) as two independent connections, with \(\nabla^i\) acting on the \(i\)-th slot or factor of \(\Phi \in \Gamma(T^*M \otimes T^*M)\), where here \(i \in \{1, 2\}\). So, the data \((A, \nabla, \psi)\) can be also replaced by \((A, \nabla^1, \nabla^2)\) in the above definition. The reason for using the parametrization with \(\psi\) becomes clear from the following:

Remark 7. Let us decompose \(\Phi\) into the sum of symmetric and skew-symmetric parts, \(\Phi = \Phi^{\text{sym}} + \Phi^{\text{skew}}\). Using the defining equations, it is easy to verify that for all \(X, Y \in \Gamma(TM)\) and \(s \in \Gamma(A)\) one has

\[
\tau \nabla^\text{comb}_s(\Phi)(X, Y) = (\tau \nabla_s(\Phi)(X, Y) - \Phi(\langle \rho(\psi s), X \rangle, Y) + \Phi(X, \langle \rho(\psi s), Y \rangle);
\]

where \(\psi s \equiv \psi(s) \in \Omega^1 M, A\) and \(\rho(\psi s) \in \Gamma(T^*M \otimes TM) \cong \Gamma(\text{End}(TM))\). Note that \(\tau \nabla^\text{comb}\) does not map symmetric 2-tensors into symmetric ones, while \(\tau \nabla\) does. As a consequence, Eq. (48) mixes \(\Phi^{\text{sym}}\) and \(\Phi^{\text{skew}}\); in detail, it decomposes into

\[
\tau \nabla_s(\Phi^{\text{sym}}) = \text{Sym}(\rho(\psi s), \Phi^{\text{skew}}),
\]

\[
\tau \nabla_s(\Phi^{\text{skew}}) = \text{Alt}(\rho(\psi s), \Phi^{\text{sym}})
\]

for all \(s \in \Gamma(A)\). Here the contraction is taken by the natural pairings \(TM \otimes \Lambda^2(T^*M) \rightarrow T^*M\) and \(TM \otimes \text{Sym}^2(T^*M) \rightarrow T^*M\), respectively, extending the pairing between \(TM\) and \(T^*M\) by the Leibniz rule. Using Eq. (31), this in turn can be rewritten in the form of Eqs. (38) with the upper sign \((\Phi^{\text{sym}} := g, \Phi^{\text{skew}} := B)\) as found in the string-physics applications (cf. also [5]). More explicitly, let \((e_a)_{a=1}^A\) be a local basis of sections, such that \(\nabla e_a = \omega^b_a e_b, \psi e_a = \psi^b_a e_b\), and \(\rho_a = \rho(e_a)\), then the Eqs. (49) read as follows:

\[
\mathcal{L}_{\rho_a} g = \omega^b_a \wedge \iota_{\rho_b} g + \psi^b_a \vee \iota_{\rho_b} B,
\]

\[
\mathcal{L}_{\rho_a} B = \omega^b_a \wedge \iota_{\rho_b} B + \psi^b_a \vee \iota_{\rho_b} g.
\]

We will come back to this example further below again.

The following construction extends that of Example [5] (cf. [14]). Before stating the proposition to be proven, we set up some noations and terminology. A bilinear form \(b\) on a vector space \(T\) uniquely corresponds to a linear map \(\tilde{b}: T \rightarrow T^*\) by \(b(v_1, v_2) = \langle \tilde{b}(v_1), v_2 \rangle\) for all \(v_1, v_2 \in V\); the bilinear form is non-degenerate if and only if \(\tilde{b}\) is invertible. It is obvious that every bilinear form with a positive (or negative) definite symmetric part is non-degenerate. Whenever the inverse map \(\tilde{b}^{-1}\) exists, it determines a bilinear form on \(T^*\) by means of \(b^{-1}(\lambda_1, \lambda_2) := \langle \lambda_1, \tilde{b}^{-1}(\lambda_2) \rangle\) for \(\lambda_1, \lambda_2 \in T^*\). We call a map \(\lambda: (T_1, b_1) \rightarrow (T_2, b_2)\)

\[\text{If, alternatively, the contraction of } TM \text{ is defined to be taken with the first factor of the respective 2-tensor only, there is a factor of } 2 \text{ to insert on the r.h.s. of each equation.}\]
such that $b_1(u, v) = b_2(\lambda(u), \lambda(v))$ for all $u, v \in T_1$ a \textit{generalized isometry}. With the above definitions and for a non-degenerate $b$, $\hat{b}: (T, b) \to (T^*, b^{-1})$ is such a generalized isometry. For every vector subspace $V \subset T$ the \textit{left-orthogonal} subspace is defined as $V^\perp = \{v \in T \mid b(v, V) = 0\}$. It follows immediately that $V$ and $V^\perp$ are complimentary if and only if the restriction of $b$ onto $V$ is non-degenerate; e.g. this is always satisfied if the symmetric part of $b$ is positive (or negative) definite. An easy computation shows that an invertible $\hat{b}$ gives rise to a generalized isometry between $(V^\perp, b|_{V^\perp})$ and $(\text{Ann}(V), b^{-1}|_{\text{Ann}(V)})$, where $\text{Ann}(V) \subset T^*$ is the annihilator of $V$.

**Proposition 11.** Given a (regular) foliation $\mathcal{F}$ of a smooth manifold $M$ equipped with a non-degenerate bilinear form $\Phi$, then its co-normal bundle $N^*\mathcal{F}$ with the canonically induced bilinear form is invariant with respect to leaf-preserving diffeomorphisms on $M$ if and only if there exist connections $\nabla^\pm$ on $A = T\mathcal{F}$ such that (48) holds true.

**Corollary 4.** If the foliated manifold has, in addition, a smooth quotient $Q = M/\mathcal{F}$, then $T^*Q$ can be equipped with a bilinear form such that for any point $p \in M$ the natural linear isomorphism $N^*_p M \to T^*_p Q$ is a generalized isometry.

**Proof** (of Proposition 11). Let $\beta_1, \beta_2$ be sections of $N^*\mathcal{F}$, the annihilator of $T\mathcal{F}$, which are transversally invariant, i.e. invariant under the action of “vertical” vector fields (vector fields parallel to $T\mathcal{F}$; this allows to identify $\beta_1$ and $\beta_2$ with 1-forms on the quotient space $Q$ whenever it is smooth). As soon as we prove that $\Phi^{-1}(\beta_1, \beta_2)$ is transversally invariant if and only if (13) is fulfilled for some $\nabla^\pm$, the assertion of Proposition 11 follows. Indeed, since the above 1-forms are invariant under the Lie derivative along any section $s$ of $A = T\mathcal{F}$, we must require that $\mathcal{L}_s (\Phi^{-1})(\beta_1, \beta_2) = 0$. Therefore the restriction of $\mathcal{L}_s (\Phi^{-1})$ to $N^*\mathcal{F}$ vanishes at every point, which is true if and only if $\mathcal{L}_s (\Phi^{-1}) \in \Gamma(T\mathcal{F} \otimes TM + TM \otimes T\mathcal{F})$. Taking into account that $\Phi$ is non-degenerate, we get that for any locally defined basis of vector fields $(\rho_a)_{a=1}^r$ of $T\mathcal{F}$, $r = \dim \mathcal{F}$, there exist two local $r \times r$ matrices $\omega^\pm$ such that the following identity holds true:

$$\mathcal{L}_{\rho_a} (\Phi^{-1}) + \rho_b \otimes \langle (\omega^+)^b_a, \Phi^{-1} \rangle + \langle (\Phi^{-1}, (\omega^-)^b_a \otimes \rho_b = 0, \quad (51)$$

where the second and the third terms of the l.h.s. are left and right contractions of a contravariant 2-tensor with a 1-form, respectively. By formula (34), extended to sections of $TM \otimes TM$, we conclude that the identity (31) is equivalent to the existence of local connections on $A$ such that $\tau_{\nabla^\text{comb}}(\Phi^{-1}) = 0$ and thus (13) is satisfied. Using a partition of unity, we obtain global connections on $A$ with the same property. \hfill \Box

**Remark 8.** If the restriction of $\Phi$ onto $T\mathcal{F}$ is non-degenerate, then so is the induced bilinear form on $T\mathcal{F}^\perp$ and, by the canonical generalized isometry, on $N^*\mathcal{F}$. Hence the bilinear form on $T^*Q$, obtained under the assumptions of Proposition 11, has an inverse, which we will denote by $\Phi_Q$.

**Example 10.** A generalized Riemannian structure on an $n$–dimensional manifold $M$ is a rank $n$ subbundle of the exact Courant algebroid $TM \oplus T^*M$ on which the inner product is positive definite; this construction has been used in several occasions already, but explicitly introduced in particular by N. Hitchin (11, cf. also 14 for an exposition of generalized geometry). A generalized Riemannian structure is in one-to-one correspondence with a bilinear form $\Phi = g + B$, where $g$ is a Riemannian metric tensor and $B$ is a skew-symmetric 2-form; the correspondence is given by the graph of $\Phi$ considered as a bundle.
map \( TM \to T^*M \). Then \( (A, \nabla^ \pm) \) is compatible with \( (M, g, B) \) if \( \tau \nabla^{\text{comb}}(g + B) = 0 \), rewritten in other ways also in Remark 4 above. Let us notice that the restriction of a generalized Riemannian structure on any subbundle of \( TM \) is non-degenerate as its symmetric part is positive definite. Thus under the assumptions of Proposition 11, Remark 3 permits us to conclude that we obtain a generalized Riemannian structure \( \Phi_Q \equiv g_Q + B_Q \) on the quotient space \( Q = M/F \).

If a bilinear form is totally skew-symmetric, \( \Phi = B \in \Omega^2(M) \), and setting \( \psi = 0 \), the equations (50) reduce to \( \tau \nabla(B) = 0 \), a compatibility condition similar in spirit to (37); locally this equation takes the form \( \mathcal{L}_{\rho_a} B = \omega^b_a \land \iota_{\rho_a} B \) (cf. Remark 7). We now consider \( B \) to be a symplectic form:

**Definition 7.** Let \( (A, \rho, \lfloor \cdot, \cdot \rfloor) \) be a Lie algebroid over a symplectic manifold \( (M, \Omega) \) and \( \nabla \) be a connection on \( A \). Then \( (A, \nabla) \) and \( (M, \Omega) \) are called compatible, if

\[
\tau \nabla(\Omega) = 0.
\]

**Example 11.** Given a (regular) foliation \( F \) on a symplectic manifold \( (M, \Omega) \) with a smooth quotient \( Q = M/F \) and a connection \( \nabla \) on \( A = TF \), such that the compatibility condition (52) is fulfilled, we immediately get a canonical bivector field on the quotient space. This follows by the same method as in Proposition 11. The bivector field on \( Q \) obtained above is clearly Poisson and so is the quotient map. In addition, the quotient Poisson structure is symplectic if and only if the restriction of \( \Omega \) on the fibers of \( F \) is non-degenerate.

Definition 7 and Example 11 admit a straightforward generalization to the Poisson case: a Lie algebroid \( A \) with a connection \( \nabla \) over \( M \) is compatible with a Poisson structure \( P \) if \( \tau \nabla(P) = 0 \). Under the assumptions of Example 11 we get a canonical Poisson structure on the quotient space \( Q = M/F \) such that the quotient map is Poisson.

**Remark 9.** For a regular foliation \( F \), transversal invariance of a tensor field is equivalent to the existence of a connection \( \nabla \) on \( TF \) such that \( \tau \nabla \) annihilates this tensor field. However, for non-regular foliations, annihilation by some \( \tau \nabla \) is a stronger requirement than transversal invariance: The standard metric \( g \) on \( \mathbb{R}^2 \) is transversally invariant with respect to the singular foliation determined by the Lie algebroid from Proposition 6. However, we proved in Proposition 6 that there is no connection \( \nabla \) such that Eq. (37) is satisfied.

### 6. Anchored bundles and free Cartan-Lie algebroids

The main idea of this part of our paper was inspired by the observation written in the last paragraph of Section 4. So far we have talked only about Lie algebroids, although some of the formulas make sense already for anchored bundles. The natural question arises whether it is possible to extend an anchored bundle supplied with a connection which is compatible with a geometric structure on the base to a Lie algebroid with a connection which obeys the same compatibility conditions. It is shown by M. Kapranov in [12] that any anchored module, a module over a commutative algebra together with a morphism of modules with values in the module of derivations of the algebra, gives rise in a canonical
A free Lie-Rinehart algebra admits a natural filtration the associated graded algebra to which is the free Lie algebra in the category of modules over the same algebra generated by this module.

We will adapt the construction of Kapranov to the category of smooth real manifolds (the original paper operates with Lie-Rinehart algebras over arbitrary ground fields). Our Theorem 2 to be proven below, is a refinement of the above-mentioned result: given any anchored bundle with a connection \((E, \nabla)\) there is a unique Cartan connection \(\nabla^{free}\) on the corresponding free Lie algebroid \(A^{free}(E)\) which extends the one on \(E\); we call it the free Cartan-Lie algebroid generated by an anchored bundle with connection. Albeit we deal only with smooth manifolds, a pure algebraic version in the spirit of [12] is quite obvious. Furthermore, if \((E, \nabla)\) is compatible with a geometric structure on the base, so is \((A^{free}(E), \nabla^{free})\). Although it would be desirable to find conditions under which the free Cartan-Lie algebroid admits a finite-dimensional reduction, for the moment we leave this problem open.

Let us denote by \(Anch_c(M)\) the category whose objects are anchored bundles with connections and morphisms are connection-preserving bundle morphisms commuting with the anchor maps. Let \(CLie(M)\) be the category of Cartan-Lie algebroids over \(M\). Every Cartan-Lie algebroid is an anchored bundle and every connection-preserving Lie algebroid morphism is a morphism of the underlying anchored bundle structures, thus there is a natural forgetful functor

\[
CLie(M) \to Anch_c(M).
\]

**Theorem 2.** The functor \((53)\) admits a left-adjoint functor

\[
FR: Anch_c(M) \to CLie(M)
\]

whose value at an anchored bundle with connection \((E, \rho, \nabla)\) is a Lie algebroid \(FR(E)\) together with a Cartan connection and an embedding of anchored bundles \(i: E \to FR(E)\), called the free Lie algebroid generated by \(E\). Thus we have a natural isomorphism

\[
\text{Hom}_{CLie(M)}(FR(E), A) = \text{Hom}_{Anch_c(M)}(E, A)
\]

for every Cartan-Lie algebroid \(A\).

In other words, for every connection-preserving morphism of anchored bundles \(\phi: E \to A\) there exists a unique Cartan-Lie algebroid morphism \(\hat{\phi}: FR(E) \to A\) such that the following diagram is commutative:

\[
\begin{array}{ccc}
E & \xrightarrow{\phi} & A \\
\downarrow{i} & & \downarrow{\hat{\phi}} \\
FR(E) & \xrightarrow{\cdot} & \end{array}
\]

**Proof.** The proof will consist of several consequential steps. First, we construct the free almost Lie algebroid \(FR^{alm}(E)\) generated by an anchored bundle \(E\). This follows by the same method as in [12]. By an almost Lie algebroid we shall mean an anchored bundle with a skew-symmetric bilinear operation which obeys all Lie algebroid properties but

---

\[15\] A Lie-Rinehart algebra is an algebraic counterpart of a Lie algebroid, cf. [22].
for the Jacobi identity, i.e. the bracket is antisymmetric, it satisfies the Leibniz rule with respect to the anchor map, and the anchor is a morphism of brackets.

We start with $FL^{alm}(E/\mathbb{R})$, the free almost Lie $\mathbb{R}$–algebra generated by the real vector space of sections of $E$, along with $FL^{alm}(E)$, the bundle of free almost Lie algebras generated by $E$ as a bundle over $M$. Recall that an almost Lie algebra is alike a Lie algebra except that the bracket operation does not necessarily respect the Jacobi identity. Both $FL^{alm}(E/\mathbb{R})$ and $FL^{alm}(E)$ are naturally graded, such that their degree $d$ factors of $FL^{alm}(E/\mathbb{R})$ and $\Gamma(FL^{alm}(E))$ are spanned by brackets involving exactly $d$ elements. It is easily seen that all homogeneous factors of $\Gamma(FL^{alm}(E))$ are finite-rank projective modules, hence we obtain the required grading of $FL^{alm}(E)$ as a vector bundle whose degree $d$ factors are finite-dimensional vector bundles, so that the fiber at $x \in M$ is naturally isomorphic to the free almost Lie algebra generated by $E_x$. The free almost Lie algebroid $FR^{alm}(E)$ is the union of an increasing sequence of anchored finite-rank bundles

$FR^{alm}_{\leq 1}(E) \subset FR^{alm}_{\leq 2}(E) \subset \ldots$,

which are defined inductively starting from $FR_{\leq 1}(E) = E$, $q_1 = id$. Suppose $FR_{\leq d}(E)$ is constructed as an anchored bundle with the anchor $\rho_d$ together with a surjective homomorphism of real vector spaces

$$FL^{alm}_{\leq d}(E/\mathbb{R}) = \bigoplus_{i=1}^{\text{dim}} FL^{alm}_d(E/\mathbb{R}) \xrightarrow{q_d} \Gamma(FR^{alm}_{\leq d}(E)),$$

then we define $FR^{alm}_{d+1}(E)$ as an anchored bundle whose space of sections is the quotient of $FL^{alm}_{d+1}(E/\mathbb{R})$ by the following relations:

$$[s, r] = 0, \ s \in \Gamma(E), r \in \text{Ker}(q_d),$$

$$[fs, s'] - [s, fs'] = \rho(s)(f)s' - \rho_d(s')(f)s, \ s \in \Gamma(E), s' \in \Gamma(FR_{\leq d}(E)).$$

The bracket on $FL^{alm}_{\leq d}(E/\mathbb{R})$ descends to a bracket on smooth sections of $FR^{alm}(E)$. The anchor map is uniquely determined by requiring the morphism property. The multiplication on smooth functions is given by the formula

$$f[s, s'] = [fs, s'] + \rho_d(s')(f)s = [s, fs'] - \rho_d(s)(f)s',$$

where $s$ and $s'$ are arbitrary sections of $FR^{alm}_{\leq d}(E)$ and $FR^{alm}_{\leq d}(E)$, respectively. The filtration $\{FR^{alm}_{\leq d}(E)\}$ makes $FR^{alm}(E)$ into a filtered almost Lie algebroid, and the associated graded almost Lie algebroid is isomorphic to $FL^{alm}(E)$ with trivial anchor map.

It is worth mentioning that in the end the image of the anchor becomes involutive and although the original anchored bundle does not necessarily carry a (singular) foliation, one now obtains an involutive (singular) tangent distribution which contains the image of $\rho$ of the original $E$.

Now we extend the connection on $E$ to the free almost Lie algebroid obtained above. For any $s, s' \in \Gamma(E)$ we claim

$$\nabla[s, s'] = L_s(\nabla s') - L_{s'}(\nabla s) - \nabla_{\rho(\nabla s)}s' + \nabla_{\rho(\nabla s')}s,$$

(57)
where $L_s$ is determined by (18). The expression (57) is well-defined as

$$\nabla ([s, fs'] - \rho(s)(f)s' - f[s, s']) = 0$$

for any smooth function $f$. This gives rise to the connection on $FR_{cd}^d(E)$ for $d = 2$. Now we proceed by induction for all $d$. Let us notice that in each step we automatically obtain $S = 0$, where $S$ is defined by the same formula (23) as in the case of a Lie algebroid.

The last task is to obtain a Cartan structure on the free almost Lie algebroid and finally on the associated free Lie algebroid.

Given an almost Lie algebroid $L$, there is a unique almost Lie algebroid structure on $J^1(L)$ compatible with prolongations in the sense of formulas (16) and (17). The construction of the brackets jet prolongation is straightforward; also there is a (sophisticated) description of the canonical almost Lie algebroid structure on the bundle of $k$-jets of $L$ in terms of supergeometry, see Remark 10 below. The notion of a Cartan connection along with the formula for the compatibility tensor does not need the bracket to obey the Jacobi identity, thus starting with a connection $\nabla$ which satisfies $S = 0$, we obtain a morphism of almost Lie algebroids $L \to J^1(L)$ determined by the corresponding splitting $\sigma$ as in (15). The Jacobiator, which values the bracket’s failure to satisfy the Jacobi identity, is defined by $Jac(s_1, s_2, s_3) = [s_1, [s_2, s_3]] + c.p.$ for every triple of sections of $L$. From the definition of an almost Lie algebroid it follows that Jac is totally anti-symmetric and $C^\infty(M)$–linear in all its arguments. Since $\sigma$ is a morphism of the brackets, one has

$$\sigma \circ Jac = Jac \circ \sigma \otimes \sigma \otimes \sigma.$$

(58)

Lemma 6. Jac is a covariantly constant map.

Proof. From (16) we obtain

$$Jac (j_1(s_1), j_1(s_2), j_1(s_3)) = j_1 (Jac (s_1, s_2, s_3))$$

for all $s_1, s_2, s_3 \in \Gamma(L)$. On the other hand, from the almost Lie algebroid counterpart of (19) and using that $\rho$ is a morphism of the brackets we have for all $\omega \in \Omega^1(M)$

$$Jac (j_1(s_1), j_1(s_2), \omega \otimes s_3) = \omega \otimes Jac (s_1, s_2, s_3).$$

(59)

From (19) and (20) we conclude that for all sectons $s_1, s_2, s_3$ and 1-forms $\omega_1, \omega_2, \omega_3$

Jac $(j_1(s_1), \omega_2 \otimes s_2, \omega_3 \otimes s_3)) = 0$,

Jac $(\omega_1 \otimes s_1, \omega_2 \otimes s_2, \omega_3 \otimes s_3) = 0$.

So we see that the only non-vanishing term of (58) is of the form (59); this implies $\nabla (Jac) = 0$ or, equivalently, that the following diagram is commutative:

$$\begin{align*}
\Gamma (\Lambda^3(L)) &\xrightarrow{Jac} \Gamma (L) \\
\nabla &\downarrow \quad \nabla \\
\Gamma (T^*M \otimes \Lambda^3(L)) &\xrightarrow{id \otimes Jac} \Gamma (T^*M \otimes L)
\end{align*}$$

Here the connection on $\Lambda^3(L)$ is extended by the Leibniz rule. This completes the proof of Lemma 6. □
Corollary 5. Any Cartan connection on an almost Lie algebroid preserves the Jacobi ideal of $L$, i.e., the ideal of sections generated by the image of the Jacobiator, thus it gives rise to a Cartan connection on the quotient Lie algebroid whenever it exists.

Let us come back to the free almost Lie algebroid generated by $E$; it is obvious that the Jacobi ideal of $FR^{\text{alm}}(E)$ inherits the filtration from the free almost Lie algebroid, such that the degree $d$ factors are finite-rank modules over the algebra of smooth functions. Hence the quotient of $FR^{\text{alm}}(E)$ by the Jacobi ideal is a Lie algebroid, which we denote by $FR(E)$. In [12] it is called the free Lie algebroid generated by $E$. By Lemma 6 and Corollary 5 we obtain the unique Cartan connection on $FR(E)$ which is compatible with the inclusion $E \hookrightarrow FR(E)$. We leave it to the reader to verify functorial properties of this construction. □

Remark 10. Let $L$ be an almost Lie algebroid. Consider $L[1] \to M$ as a graded superbundle with the degree 1 odd fibers. In the way similar to the Lie algebroid case [25], an almost Lie algebroid structure is in one-to-one correspondence with a degree 1 vector field $Q$ on $L[1]$, defined by the Cartan’s formula, such that $Q^2$ commutes with all smooth functions on the base $M$. However, in contrast to Lie algebroids, the odd vector field $Q$ is not necessarily homological, as $Q^2 = 0$ is equivalent to the Jacobi identity for the almost Lie algebroid structure on $L$. Now the canonical prolongation of $Q$ to the total space of $J^k(L[1]) = J^k(L)[1]$ determines an almost Lie algebroid structure on the space of $k$–jets of $L$ compatible with the given one on $L$.

A possible adaptation of Proposition 2 is to take $E$ to be an anchored bundle and $\nabla$ to be a connection on $E$. In this setting, the formula (34) still makes sense and the operator $^\tau\nabla$ is well-defined, although is is not an $A$-connection any more.

Definition 8. Let $(E, \rho)$ be an anchored bundle on $M$ and $\nabla^1, \ldots, \nabla^m$ be vector bundle connections on $E$ which give rise to $^\tau\nabla^1, \ldots, ^\tau\nabla^m$ on tensor forms on $M$. An $m$–linear form $\chi$ is called compatible with $(E, \nabla^1, \ldots, \nabla^m)$ if $^\tau\nabla^\text{comb}(\chi) = 0$, where $\nabla^\text{comb}$ is constructed in the same manner as in Definition 6 and Remark 6.

Proposition 12. Let $(E, \rho, \nabla^1, \ldots, \nabla^m)$ be an anchored bundle with $m$ connections and $\chi$ be an $m$–linear form on the base $M$, such that the compatibility condition $^\tau\nabla^\text{comb}(\chi) = 0$ holds true. Let us extend $\nabla^1, \ldots, \nabla^m$ to the corresponding Cartan connections $\tilde{\nabla}^1, \ldots, \tilde{\nabla}^m$ on $FR(E)$. Then $\left(FR(E), \tilde{\nabla}^1, \ldots, \tilde{\nabla}^m\right)$ and $(M, \chi)$ are also compatible.

Proof. Given that each $\tilde{\nabla}^i$ on $FR(E) =: A$ respects the Lie algebroid structure in the sense of $S = 0$, we can apply Proposition 2. It follows that all $A$-connections obtained in this way are Lie algebroid representations of $FR(E)$, hence so is the combined $A$-connection. Since the free Lie algebroid is generated by $E$, i.e. the space of its sections is spanned over smooth functions by all multiple brackets of sections of $E$, the identity $^\tau\nabla^\text{comb}_s(\chi) = 0$ for all $s \in \Gamma(E)$ implies $^\tau\nabla^\text{comb}_s(\chi) = 0$ for all sections $\xi$ of $FR(E)$, which gives the proof of the desired property. □
Appendix A: Flat Killing Lie algebroids, simple examples and facts

A typical example of a flat Killing Cartan Lie algebroid, i.e. a Killing Cartan Lie algebroid as defined in Definition 4, such that $\nabla$ is flat but which is not just an action Lie algebroid mapping into isometries by means of $\rho$, but locally so only (cf. also Example 6), is the following one.\footnote{This example was suggested to us by A. Weinstein.}

**Example 12.** Consider the unit square $[0,1] \times [0,1] \subseteq \mathbb{R}^2$ with an identification of opposite sides so as to yield a Klein bottle $M$. Equipping $M$ with the natural metric $g$ and its Levi-Civita connection $\nabla$, we get another example of a flat Killing Lie algebroid. Similarly, the foliation of $\mathbb{R}^2$ by vertical lines induces a foliation $\mathcal{F}$ on $M$ and $(\mathcal{T}\mathcal{F},\nabla,g)$ forms a sub-Killing Lie algebroid of the previous one. In both cases, locally constant sections correspond to local Killing vectors, while some of them do not extend to globally constant (non-zero) sections due to the non-triviality of the bundles.

For the same reason, $TM$ and $T\mathcal{F}$ cannot be action Lie algebroids in the last example, while locally they are, corresponding to the fact that some of the local isometries of the Klein bottle do not extend to global ones.

Note that one cannot expect to necessarily always find all Killing vectors as coming from constant sections, also not locally. Here two examples, both of which are in fact also (flat Killing) Cartan Lie algebroids:

**Example 13.** Let $M = \mathbb{R}^n$ with its standard flat metric $g$, $A$ the standard Lie algebroid $A := TM \cong \mathbb{R}^n \times \mathbb{R}^n$, equipped with its standard flat connection of a vector space. It shows that there are Killing vectors which do not arise from flat sections: While the generators of translations, $\partial_i$, are constantly covariant and Killing vectors by the above argument, the generators of rotations, $m_{ij} := x^i \partial_j - x^j \partial_i$, $i \neq j$, are Killing vectors of $g$ without being covariantly constant. In fact, there is no (globally defined) connection $\nabla$ on $TM$ making these generators covariantly constant.

**Example 14.** Let $M_0 = S^2 \subseteq \mathbb{R}^3$ equipped with its standard metric of constant curvature. Denote by $e_1$, $e_2$, and $e_3$ a basis of the three-dimensional isometry Lie algebra so(3). Consider a region $M \subset M_0$ where $e_1$ and $e_2$ are non-zero everywhere. Let $A = TM$ be the standard Lie algebroid over this $M$. Define a connection on $A$ by requiring $\nabla e_1 = 0 = \nabla e_2$. Now since on $M$ one has $e_3 = f_1 e_1 + f_2 e_2$ for non-constant functions $f_1$ and $f_2$, $\nabla e_3 \neq 0$, while still $\rho(e_3) = [\rho(e_1),\rho(e_2)]$ is a Killing vector field.

In both of these examples, the bundle has smaller rank than the dimension of isometry group of the Riemannian base manifold. But the situation in this context here can be also reversed easily: There is a simple procedure to construct flat Killing Lie algebroids of higher rank from any given: Let $(A_0,\nabla_0,g)$ be a flat Killing Lie algebroid over a manifold $M$. Choose any Lie algebroid extension $A$,

$$0 \rightarrow B \rightarrow A \rightarrow A_0 \rightarrow 0,$$

of $A_0$ by a bundle of Lie algebras $B$ over $M$. Assume that $A$ admits a flat connection $\nabla$ projecting to $\nabla_0$ on $A_0$. Then the triple $(A,\nabla,g)$ also defines a flat Killing Lie algebroid. Note that here the image of $\rho$ and of $\rho_0$ coincide at each $x \in M$. 

In general, the relation of a flat Killing Lie algebroid to an action Lie algebroid with identically induced foliation can be intricate. What always holds true, however, is stated in the following

**Proposition 13.** Let $(A, \nabla, g)$ be a flat Killing Lie algebroid over $M$, i.e. a Killing Lie algebroid where $\nabla$ is flat. Then every point $x \in M$ permits a neighborhood $x \ni U \subset M$ over which there exists a finite-rank action Lie algebroid the induced singular foliation of which is identical to the one of $A|_U$. This action Lie algebroid is canonically a flat Killing Cartan Lie algebroid.

**Proof.** For every $x \in M$ we may choose a neighborhood with a covariantly constant basis $(e_a)_{a=1}^{\text{rk}A}$ of sections $e_a \in \Gamma(A|_U)$ satisfying $\nabla e_a = 0$. Its image by $\rho$ provides a set of Killing vectors which, over $C^\infty(U)$, generates the image of $\rho|_U$—the integral surfaces of this (possibly singular) distribution provides the (possibly singular) foliation of $U$. Taken over $\mathbb{R}$, the same set of Killing vectors generates a finite-dimensional Lie algebra $g_U$ acting on $U$. $U \times g_U$ is the searched-for action Lie algebroid. □

**Remark 11.** In both examples Example 13 and Example 14, the action Lie algebroid constructed along the above lines glues together to globally flat Killing Cartan Lie algebroids $M \times \text{iso}(g)$ where $\text{iso}(g)$ is the full isometry Lie algebra of $g$. In Example 14, e.g., $M \times \text{so}(3)$ (equipped with its canonical flat connection). There now is a Lie algebroid morphism from this action Lie algebroid into the original (flat Killing Cartan) Lie algebroid $A = TM$, by mapping the standard $\text{so}(3)$-basis to $e_1, e_2, e_3$. However, this morphism does not respect the connection $\nabla$, and thus is not a morphism in the category of Killing Lie algebroids. In Example 12, on the other hand, we found a local isomorphism as (flat Cartan) Killing Lie algebroids.
