Keywords: magnesium alloy, microstructure, tensile strength, strengthening phase

Abstract. The tensile strength stability of aging hardened Mg-5Y-3Sm-0.5Sb alloy was primarily studied. The results showed that the alloy has good tensile strength at room and high temperature. The tensile strength decreases slowly from 258 MPa at room temperature to 195 MPa at 300 °C. The tensile strength stability is superior to that of commercial heat resistant magnesium alloy WE54 developed most successfully. The formation of Mg24Y5 phase is observed in the alloy. The tensile strength of the alloy keeps a linear relationship with the hardness of strengthening phase Mg24Y5. The reason for the tensile strength stability is mainly attributed to the hardness stability of Mg24Y5 phase in the alloy.

1. Introduction

Mg-RE (rare earth elements) alloys are interesting materials since they have excellent room and high temperature mechanical properties [1, 2]. Simultaneous addition of two or more kinds of rare earth elements from different subgroups (Y subgroup, Ce subgroup) can produce good solid solution strengthening and precipitation strengthening, and enhance comprehensive mechanical properties of magnesium alloys [3]. As one of Y subgroup (heavy) rare earth elements, Y is considered to be one of the most effective rare earth elements to improve mechanical properties of magnesium alloys at high temperatures [4, 5]. As one of Ce subgroup (light) rare earth elements, Sm has a unique orthorhombic structure and a high solid solubility in Mg [6]. Therefore, Y and Sm is an interesting combination of rare earth elements, and Mg-Y-Sm alloy is a new type of heat resistant magnesium alloy [7].

Heat resistant Mg-Y-Sm alloys have been attached more and more importance due to their good strength and creep resistance at high temperature. They exhibit better strength and creep resistance than commercial Mg-Y-RE (WE) alloys at high temperature [8-10]. They have important application value and broad application prospect in aerospace, automotive, electronics and other fields. However, their strength stability has few been investigated. In the present work, the tensile strength stability of Mg-Y-Sm-Sb alloy is primarily studied.
2. Experimental

Metallic magnesium, antimony, Mg-25Y and Mg-25Sm (mass fraction, %) master alloys were used as raw materials. All the raw materials were baked before melting. The chemical composition of tested alloy was designed as Mg-5Y-3Sm-0.5Sb (mass fraction, %). The alloy was melted in an induction furnace and cast in a preheated steel mold. Then, T6 treatment including solid solution (525 °C, 6 h) and aging treatment (225 °C, 12 h) was conducted for the cast alloy.

The tensile tests were carried out at a strain rate of 1mm/min in AG-I 250kN precision universal material testing machine at room temperature (20 °C) and high temperature (200 °C, 250 °C, 300 °C). The gauge section size of tensile specimen is Ø6 mm×30 mm. The high temperature tensile tests were performed in an electric resistance furnace. The samples were held for about 5 min prior to the tensile test to reach a thermal equilibrium.

The phases were analyzed by D8 Advance X-ray diffraction meter (XRD) and MDI Jade 5.0 software. The microstructure was examined by Olympus optical microscope (OM) and JSM-5610LV scanning electron microscope (SEM) with energy dispersive spectroscopy (EDS).

3. Results

The tensile test results show that aging hardened Mg-5Y-3Sm-0.5Sb alloy has good tensile strength at room and high temperature. At room temperature, the tensile strength of the alloy is only 258 MPa. With the increase of temperature, the tensile strength decreases slowly, from 243 MPa at 200 °C to 233 MPa at 250 °C and 195 MPa at 300 °C. It can be drawn that the tensile strength is stable and insensitive to the change of temperature. As a whole, the strength properties of the alloy are good at room temperature (20 °C) and high temperature (200-300 °C). Considering applied requirement of tensile strength, the maximum applied temperature of the alloy is up to 300 °C.

Among Mg-Y-RE (WE) alloys, WE54 (Mg-5.1%Y-3.3%RE(Nd)-0.5%Zr) alloy is one of the heat resistant magnesium alloys developed most successfully. It has good strength properties at room and high temperature. Its tensile strength is 280 MPa at room temperature, 240 MPa at 200 °C, 230 MPa at 250 °C and 180 MPa at 300 °C. Its heat resistant temperature is up to 300 °C [11]. By contrast, the tensile strength of Mg-5Y-3Sm-0.5Sb alloy is lower than that of WE54 alloy at room temperature. However, the tensile strength of Mg-5Y-3Sm-0.5Sb alloy is higher than that of WE54 alloy from 200 °C to 300 °C. As a result, the tensile strength of Mg-5Y-3Sm-0.5Sb alloy is more stable from room temperature to 300 °C. Its tensile strength stability is superior to that of heat resistant magnesium alloy WE54 developed most successfully. It is very helpful to enhancing the safety and reliability of magnesium alloy components working under high temperature. The reason for the tensile strength stability of the alloy requires further research.

Figure 1 shows the microstructure and XRD pattern of aging hardened Mg-5Y-3Sm-0.5Sb alloy. It can be seen that the microstructure of the alloy consists of white matrix and black particles. According to the relative phase diagrams and XRD pattern, there are Mg matrix and Mg_{24}Y_{5}, Mg_{41}Sm_{5}, Mg_{3}Sb_{2} phases in the alloy. It can also be seen that the microstructure of the alloy has two outstanding features: (1) the grain is uniform but its average size is not very small; (2) the particle phases distributes dispersedly in the alloy but some of them are not very small.
Figure 1 Microstructure (a) and XRD pattern (b) of Mg-5Y-3Sm-0.5Sb alloy.

Figure 2 shows SEM image of the microstructure and EDS analysis results of particle A in aging hardened Mg-5Y-3Sm-0.5Sb alloy. It can be seen that the particle phase consists of four elements Mg, Y, Sm and Sb. The content of Mg and Y is high but the content of Sm and Sb is very low. Considering the XRD pattern in Figure 1, the formation of Mg_{24}Y_{5} phase is detected in the alloy. It can be drawn that the particle phase should be Mg_{24}Y_{5}. And the existence of Sm and Sb in the particle phase can be explained to be the dissolving of part Sm and Sb in Mg_{24}Y_{5} phase. As a result, the stability of strengthening phase Mg_{24}Y_{5} is enhanced with the dissolving of Sm and Sb.

Figure 2 SEM image showing microstructure (a) and EDS analysis results of particle A (b) in Mg-5Y-3Sm-0.5Sb alloy.

At high temperature, the strength of magnesium alloy depends on strengthening phases at grain boundaries. Considering the microhardness of phases in magnesium alloy (see Table 1)[12], the thermal stability of Mg_{24}Y_{5} phase in Mg-Y alloy is much higher than that of Mg_{17}Al_{12} phase in Mg-Al alloy. The thermal stability of strengthening phase determines the heat resistant temperature of the alloy and its position in heat resistant magnesium alloys. Judged from that the hardness drop of strengthening phase is less than 20%, the heat resistant temperature of Mg-Al alloy does not exceed 200 °C. It is consistent with the previous research results. The hardness of Mg_{24}Y_{5} decreases slowly with the increase of temperature, from 218HV at 20 °C to 173HV at 300 °C, and the drop is a little more than 20%. So Mg-Y-RE alloy (such as WE54) has good heat resistance and its maximum applied temperature is up to 300 °C.

Table 1 Microhardness of some phases in magnesium alloy.

| Phase     | Microhardness / HV |
|-----------|---------------------|
| Mg_{24}Y_{5} | 218   201  196  173 |
| Mg_{17}Al_{12} | 183   158  125  84  |

In order to find out the reason for strength stability of aging hardened Mg-5Y-3Sm-0.5Sb alloy, the relationship between tensile strength of Mg-5Y-3Sm-0.5Sb alloy and microhardness of Mg_{24}Y_{5} is investigated.
phase is plotted and fitted linearly (see Figure 3). It can be seen that the tensile strength keeps a linear relationship with the microhardness of Mg$_{24}$Y$_5$ phase. So the reason for tensile strength stability is mainly attributed to the hardness stability of strengthening phase Mg$_{24}$Y$_5$. Of course, Sm and Sb also play an important role in the alloy. The dissolved Sm and Sb enhance the thermal stability and thereby the dispersion strengthening effect of Mg$_{24}$Y$_5$ phase in the alloy. Therefore, Mg$_{24}$Y$_5$ phase keeps high hardness at high temperature and still acts as a bar to dislocation movement and boundary sliding and therefore improves the strength properties of the alloy at high temperature. In addition, strengthening phases Mg$_{41}$Sm$_5$ and Mg$_3$Sb$_2$ in the alloy are helpful to enhance the strength stability to some extent.

4. Conclusions

In this work, aging hardened Mg-5Y-3Sm-0.5Sb alloy has good tensile strength at room and high temperature. With the increase of temperature from room temperature to 300 °C, the tensile strength of the alloy decreases slowly from 258 MPa to 195 MPa. The tensile strength stability of the alloy is superior to that of heat resistant magnesium alloy WE54 developed most successfully. The reason for the tensile strength stability is mainly attributed to the hardness stability of strengthening phase Mg$_{24}$Y$_5$ in the alloy.
