Abstract Geodesic observers in cosmology are revisited. The coordinates based on freely falling observers introduced by Gautreau in de Sitter and Einstein-de Sitter spaces (and, previously, by Gautreau & Hoffmann in Schwarzschild space) are extended to general FLRW universes. We identify situations in which the relation between geodesic and comoving coordinates can be expressed explicitly in terms of elementary functions. In general, geodesic coordinates in cosmology turn out to be rather cumbersome and limited to the region below the apparent horizon.

Keywords cosmology · geodesic observers · Gautreau-Hoffmann-like coordinates

1 Introduction

Geodesic observers in radial free fall, and the associated coordinates, were introduced in Schwarzschild spacetime long ago by Ronald Gautreau and Banesh Hoffmann \cite{1} (see also \cite{2,3,4,5,6,7,8,9} and Refs. \cite{10,11,12,13,14} for recent interest). Gautreau used them also in Friedmann-Lemaître-Robertson-Walker (FLRW) cosmology \cite{15,16}. Gautreau’s \cite{16} key idea was to use freely falling observers to describe spatially homogeneous and isotropic cosmology, therefore the Gautreau-Hoffmann coordinates in Schwarzschild \cite{11} and their analogue in FLRW \cite{15,16} spacetimes should properly be called “geodesic coordinates”. Gautreau’s motivation for using these coordinates in cosmology in his 1983 \cite{15} and 1984 \cite{16} papers remains rather obscure, since it is far more natural to describe cosmology from the point of view of comoving observers (those that see the cosmic microwave background spatially homogeneous and isotropic around them, apart from the tiny temperature perturbations $\delta T / T_0 \approx 5 \cdot 10^{-5}$ discovered by the COBE satellite in 1992). However, today there is a large literature on the mechanics and thermodynamics of apparent horizons which often require alternative coordinates.\cite{16} Cosmological horizons are increasingly studied as almost trivial examples of apparent horizons to test properties of the analogous (but more complicated) apparent horizons of dynamical black holes. Moreover, cosmology has expanded significantly with 1) the inflationary paradigm of the early universe; 2) the discovery of cosmic microwave background temperature fluctuations in 1992, and 3) the 1998 discovery, made with type Ia supernovae, of the present acceleration of the cosmic expansion. This significant growth of cosmology and of horizon mechanics and thermodynamics motivates the exploration of subjects that were marginal in the past, in particular contemplating alternative coordinate systems in cosmology is more motivated today than it was in the 1980s.

Gautreau \cite{16} restricted himself to spatially flat universes, then further restricted to Einstein-de Sitter universes in which the fluid is a dust and the comoving observers are geodesic \cite{16}, or to an empty and locally static de Sitter universe \cite{15} with positive cosmological constant $\Lambda$. Then, he further restricted himself to the discussion of geodesic observers starting their radial free fall from the origin $r = 0$. We would like to go beyond all these limitations.

The approach of Refs. \cite{15} and \cite{16} is rather indirect: Gautreau first writes the FLRW line element as a generic spherically symmetric one using the areal radius as the radial coordinate, and then solves the Einstein equations. Only later, spatial homogeneity and isotropy are imposed. There is no need to do this as the FLRW geometry describing spatial homogeneity and isotropy is well known \cite{20}. Probably

\textsuperscript{1}See, for example, Refs. \cite{17,18} for the use of Painlevé-Gullstrand coordinates to describe the thermodynamics of the Schwarzschild horizon and Ref. \cite{19} for the de Sitter horizon.
due to the lack of a widespread geometric view at the time of writing. Gautreau’s papers are rather obscure on several points that can use a transparent geometric clarification or reformulation. In several other points the reasoning is vague or borderline incorrect (for example, comoving observers are confused with geodesic ones, although this no longer matters when Gautreau specializes to a dust fluid, but becomes crucial when attempting to move beyond this limitation). Certain reasonings are ultimately correct, but this can only be established a posteriori. As a result, the average reader would remain suspicious about the derivation of geodesic coordinates in and would avoid using them.

Here we revisit critically the Gautreau construction of geodesic coordinates and we attempt to give a more direct and transparent treatment, while removing the heavy restrictions of Refs. and . We begin by using the FLRW geometry in comoving coordinates from the outset, then transforming to Gautreau-Hoffmann-like coordinates employing the areal (or “curvature”, or “Schwarzschild-like”) radius as the radial coordinate and the proper time of radial geodesic observers as the time coordinate. We elucidate several points not addressed in Refs. and . As will be clear in the following sections, connecting geodesic coordinates with the more natural comoving coordinates cannot always be done explicitly, in particular for spatially curved FLRW universes.

We highlight situations in which the relation between geodesic and comoving time can be calculated explicitly in terms of elementary functions, and we provide explicit examples of physical interest. It turns out that geodesic coordinates in FLRW cosmology are rather cumbersome and only cover the region of FLRW space below the apparent horizon. Indeed, the discussion of radial geodesic observers quickly becomes very involved and, to keep it manageable, we will restrict ourselves to observers initially comoving with the cosmic fluid. Likewise, we only consider FLRW universes sourced by a single perfect fluid in the context of Einstein’s theory of gravity.

We follow the notation of Ref. ; the metric signature is and we use units in which Newton’s constant and the speed of light are unity.

2 Geodesic and quasi-geodesic observers in FLRW universes

Here we introduce geodesic coordinates in FLRW spacetime, which are analogous to the Gautreau-Hoffmann co-

\[ ds^2 = -dt^2 + a^2(t) \left( \frac{dr^2}{1 - kr^2} + r^2 d\Omega_2^2 \right), \]

(1)

where \( a(t) \) is the scale factor describing the expansion history of the universe, \( k \) is the curvature index normalized to 0, ±1, and \( d\Omega_2^2 \equiv d\vartheta^2 + \sin^2 \vartheta d\varphi^2 \) is the line element on the unit 2-sphere. We then introduce the areal radius \( R(t, r) = a(t)r \), which is analogous to the Schwarzschild radius and is the radial coordinate in the Gautreau coordinate system. In principle, in a FLRW universe one could also use the proper radius defined by

\[ R_p = a(t) \int \frac{dr}{\sqrt{1 - kr^2}} = a(t)\chi, \]

(2)

where \( \chi \) is the hyperspherical radius often used in cosmology and

\[ f(\chi) = r \equiv \begin{cases} \sin \chi & \text{if } k = +1, \\ \chi & \text{if } k = 0, \\ \sinh \chi & \text{if } k = -1, \end{cases} \]

(3)

which turns the FLRW line element into

\[ ds^2 = -dt^2 + a^2(t) \left( d\chi^2 + f^2(\chi) d\Omega_2^2 \right). \]

(4)

\( R_p \) is a “volume radius” rather than an areal radius and coincides with \( R \) only for spatially flat \( k = 0 \) universes. Gautreau & Hoffmann used the areal radius \( R \) instead of the proper radius \( f \). In the Schwarzschild geometry

\[ ds^2 = - \left( 1 - \frac{2m}{R} \right) dt^2 + \frac{dr^2}{1 - \frac{2m}{R}} + R^2 d\Omega_2^2, \]

(5)
hence the analogue of their coordinates in FLRW space should use the areal radius $R$ as well. Defining the proper time of geodesic observers and linking it with the time coordinate $t$ of comoving observers is considerably more complicated than introducing the areal radius $R$.

2.1 Timelike radial geodesics in FLRW

Let us begin by characterizing the radial timelike geodesics of FLRW spacetime. The non-vanishing Christoffel symbols of the FLRW geometry in comoving coordinates ($t, r, \vartheta, \varphi$) are

$$
\Gamma^t_{rr} = \frac{aa}{1 - kr^2},
$$

$$
\Gamma^r_{r\vartheta} = 1 - kr^2,
$$

$$
\Gamma^\vartheta_{\vartheta r} = kr^2 a^2 \sin^2 \vartheta,
$$

$$
\Gamma^r_{\vartheta \varphi} = -r (m1 - kr^2) \sin^2 \vartheta,
$$

$$
\Gamma^\varphi_{\vartheta \varphi} = \sin \vartheta \cos \vartheta,
$$

$$
\Gamma^\varphi_{\vartheta \varphi} = \Gamma^\varphi_{\varphi \vartheta} = \cot \vartheta,
$$

$$
\Gamma^\varphi_{r \varphi} = \Gamma^\varphi_{\varphi r} = \Gamma^\varphi_{\varphi \varphi} = \frac{1}{r},
$$

where an overdot denotes differentiation with respect to the comoving time $t$. A radial timelike geodesic with proper time $\tau$ and four-velocity components

$$
u^\mu = \frac{dx^\mu}{d\tau} = (u^t, u^r, 0, 0)
$$

satisfies the geodesic equations

$$
\frac{du^t}{d\tau} + 2 \Gamma^t_{rr} u^r u^t = 0,
$$

$$
\frac{du^r}{d\tau} + 2 \Gamma^r_{r\vartheta} u^\vartheta u^r = 0.
$$

Dividing by $u^t = dt/d\tau$, one obtains

$$
\frac{d}{dt} \left[ \ln(u^t) + 2 \ln \left( \frac{a}{a_0} \right) \right] = 0,
$$

which integrates to

$$
u^t = u^t(0) \frac{a^2}{a^2_0},
$$

where $u^t(0) \equiv u^t(t_0)$ is the initial condition at the comoving time $t_0$ and $a_0 = a(t_0)$. The normalization of the four-velocity $g_{ab} u^a u^b = -1$ gives

$$-(u^t)^2 + \frac{a^2}{1 - kr^2} (u^r)^2 = -1
$$

and Eq. (19) then yields

$$u^t = \sqrt{1 + \left( \frac{u^t(0)^2 a_0^4}{a^2(1 - kr^2)} \right)}
$$

where the positive sign of the square root is chosen in order for $u^t$ to be future-oriented. If the geodesic particle is initially at rest in comoving coordinates (i.e., initially comoving with the cosmic fluid) at time $t_0$ and position $x_\mu = (t_0, r_0, \vartheta_0, \varphi_0)$, then the components of its four-velocity are

$$u^\mu_0 = (1, 0, 0, 0),$$

that is, the four-velocity coincides with that of a radial timelike geodesic. In other words, if the freely falling particle is initially comoving with the cosmic fluid, it remains comoving at all times. This point was missed in Refs. [15, 16].

The time component of the geodesic equation then becomes

$$
\frac{du^t}{d\tau} + \frac{aa}{1 - kr^2} \left( \frac{u^t(0)}{a} \right)^2 = 0,
$$

which integrates to

$$u^t = \frac{dt}{d\tau} = \alpha t + \beta
$$

(with $\alpha$ and $\beta$ integration constants) and

$$t(\tau) = \frac{\alpha}{2} \tau^2 + \beta \tau + \gamma,$$

where $\gamma$ is another integration constant. For the FLRW cosmic fluid, $t$ is the proper time of the fluid particles, while $\tau$ is the proper time of massive test particles: the two do not coincide unless the fluid is a dust.

2.2 Pseudo-Painlevé-Gullstrand coordinates

By switching from comoving radius $r$ to the areal radius $R(t, r) = a(t) r$, and using the relation between differentials $dr = (dR - HDR dt) / a$, the FLRW line element ([1] assumes the non-diagonal form (dubbed “pseudo-Painlevé-Gullstrand” form) [23])

$$ds^2 = \left( 1 - \frac{H^2 R^2}{1 - kr^2/a^2} \right) dt^2 - \frac{2HR}{1 - kr^2/a^2} dtdR
$$

$$+ \frac{dR^2}{1 - kr^2/a^2} + R^2 d\Omega^2(2),$$

3Note that the initial radius of the geodesic observer is not restricted to vanish, as in [15, 16].

4This line element resembles the Painlevé-Gullstrand line element for the Schwarzschild geometry but, unless $k = 0$, it lacks the defining feature of Painlevé-Gullstrand coordinates that the constant time slices are flat [23, 31, 32].
where $H \equiv \dot{a}/a$ is the (comoving time) Hubble function. In these coordinates, the four-velocity normalization reads
\[
\left(-1 + \frac{H^2 R^2}{1 - kR^2/a^2} \right) (u')^2 - \frac{2HR}{1 - kR^2/a^2} u^R u' R
\]
\[+ \left( \frac{(u')^2}{1 - kR^2/a^2} \right) = -1 \quad (27)
\]
and can be rewritten in the form
\[- (u')^2 + \frac{1}{1 - kR^2/a^2} (u^R - HRu')^2 = 0 \quad (28)
\]
that will be useful later. Eq. (27) is solved for $u^R$, yielding the quadratic equation
\[
(u^R)^2 - 2HRu' u^R - \left(1 - H^2 R^2 - \frac{kR^2}{a^2} \right) (u')^2 + 1 - \frac{kR^2}{a^2} = 0 \quad (29)
\]
with roots
\[u^R = HRu' \pm \sqrt{1 - \frac{kR^2}{a^2} \sqrt{(u')^2 - 1}. \quad (30)}
\]
The argument of the square root can be rewritten as
\[
\left(1 - \frac{kR^2}{a^2} \right) [(u')^2 - 1], \quad (31)
\]
so that
\[u^R = HRu' \pm \sqrt{1 - \frac{kR^2}{a^2} \sqrt{(u')^2 - 1}. \quad (32)}
\]
We can now relate the components of the four-velocity in pseudo-Painlevé-Gullstrand coordinates to those in comoving coordinates. Since
\[u^R = \frac{dR}{d\tau} = \frac{dt}{d\tau} + a \frac{dr}{d\tau} = \frac{a}{R} R u' + au', \quad (33)
\]
and
\[u' = \frac{u^R}{a} = HR u' + au', \quad (34)
\]
applying Eqs. (19) and (21) to the second of Eqs. (34) gives
\[u^R = HR \sqrt{1 + \frac{(u')^2}{a^2} \frac{\sigma_0^2}{1 - kR^2/a^2} \pm \frac{(u')^2}{a^2} \frac{\sigma_0^2}{a^2}}. \quad (35)
\]
We now impose the special initial condition\[^5\]
\[R(t_0) = R_0, \quad (36)
\]
\[u^R(0) = 0, \quad (37)
\]
\[^5\]Gautreau imposes the special initial position $R_0 = 0$ invoking the cosmological principle—the meaning of this statement is unclear. We do not impose this unnecessary restriction and the geodesic clock can be dropped from any initial position below the apparent horizon.

at $t = t_0$ (or $\tau = \tau_0$). Physically, this means that the geodesic clock is released from rest at $R_0$, where “at rest” means $dR/d\tau \equiv u^R = 0$. With these initial conditions, the normalization (27) gives
\[
\left(1 - \frac{H_0^2 R_0^2}{1 - kR_0^2/a_0^2} \right) (u'_{(0)})^2 = 1 \quad (38)
\]
and the initial time component
\[u'_0 = \frac{H_0 R_0}{a_0} \sqrt{1 - \frac{kR_0^2}{a_0^2} / (1 - kR_0^2/a_0^2)} - \frac{H_0}{a_0} \sqrt{1 - \frac{kR_0^2}{a_0^2} / (1 - kR_0^2/a_0^2) \sqrt{2H_0^2 R_0^2 - kR_0^2/a_0^2}}. \quad (39)
\]
Substituting this expression into the first of Eqs. (34) yields
\[u'_0 = - \frac{H_0 R_0 u'_0}{a_0} \quad (40)
\]
and, finally,
\[u'_0 = \frac{H_0 R_0}{a_0} \sqrt{1 - \frac{kR_0^2}{a_0^2} / (1 - kR_0^2/a_0^2) \sqrt{2H_0^2 R_0^2 - kR_0^2/a_0^2}}. \quad (41)
\]
Eq. (41) agrees with what one obtains by setting $u'_0 = 0$ in Eqs. (35) and (28). Using the normalisation of the four-velocity in comoving coordinates and Eq. (41), one obtains
\[u' = \frac{\sigma_0^2 H_0^2 R_0^2}{a^2 (1 - kR^2/a^2)} \frac{1 - kR_0^2/a_0^2 - H_0^2 R_0^2}{1 - kR_0^2/a_0^2} + 1 \quad (42)
\]
along the radial timelike geodesics with the special initial condition (26), (27). As a check, Eq. (42) agrees with Eq. (39) at the spacetime point $(t_0, R_0, \dot{\theta}_0, \dot{\varphi}_0)$.

The use of Eqs. (35) and (41) then leads to
\[u^R = HR \sqrt{1 + \frac{\sigma_0^2}{a^2} \frac{(u'_{(0)})^2}{a^2} (1 - kR^2/a^2) \pm \frac{(u'_{(0)})^2}{a^2} \frac{\sigma_0^2}{a^2}}. \quad (43)
\]
which (as a check) satisfies \( u^R_0 = 0 \) at \( R_0 \). For an observer initially at rest (i.e., \( u^R_0 = 0 \)), the relation (34) suggests that

\[
u' = \frac{-H_0 R_0 u^R_0}{a_0} < 0 ;
\]

(44)

of course, if this geodesic observer is at rest in the Gautreau-Hoffmann sense, it is left behind by the comoving observers and its radial velocity according to the comoving observers is negative.

In the following we need the components of the four-velocity covector

\[
u = g_{\alpha \alpha} u^\alpha
\]

\[
= \left( 1 - \frac{H^2 R^2}{1 - kr^2/a^2} \right) u' \frac{HR}{1 - kr^2/a^2} u^R
\]

\[
= \frac{a_0 H_0 R_0 R}{a (1 - kr^2/a^2)} \sqrt{\frac{1 - kr^2/a_0^2}{1 - kr^2/a_0^2 - H_0^2 R_0^2}}
\]

\[
- \sqrt{1 + \frac{a_0^2 H_0^2 R_0^2}{a^2 (1 - kr^2/a^2)} \frac{1 - kr^2/a_0^2}{1 - kr^2/a_0^2 - H_0^2 R_0^2}}.
\]

(45)

and

\[
u = g_{R \alpha} u^\alpha
\]

\[
= \frac{HR}{1 - kr^2/a^2} + \frac{1}{1 - kr^2/a^2} u^R
\]

\[
= \frac{a_0 H_0 R_0}{a (1 - kr^2/a^2)} \sqrt{\frac{1 - kr^2/a_0^2}{1 - kr^2/a_0^2 - H_0^2 R_0^2}}.
\]

(46)

2.3 Geodesic coordinates

The Gautreau-Hoffmann-like geodesic coordinates are \((T, R, \theta, \phi)\), where \( T \) is the proper time of clocks freely falling from rest (i.e., \( u^R_0 = 0 \) initially). The relation between \( T \) and the comoving time \( t \) is given by \( u^\tau \equiv dt/dT \) and \( d\tau = dt/u^\tau \).

In finite terms,

\[
\tau = \int \frac{dt}{u^\tau}
\]

\[
= \int dt \left( \frac{a_0^2 H_0^2 R_0^2}{a^2 (1 - kr^2/a^2)} \frac{1 - kr^2/a_0^2}{1 - kr^2/a_0^2 - H_0^2 R_0^2} \right)^{-1/2}
\]

\[
= \int dt \sqrt{(a^2 - kr^2) (1 - \frac{kr^2}{a_0^2} - H_0^2 R_0^2)}
\]

\[
\times \left[ (a^2 - kr^2) (1 - \frac{kr^2}{a_0^2} - H_0^2 R_0^2) + a_0^2 H_0^2 R_0^2 \left( 1 - \frac{kr^2}{a_0^2} \right) \right]^{-1/2}.
\]

(48)

Using the notation

\[
a_0 = 1 - \frac{kr^2}{a_0^2} - H_0^2 R_0^2,
\]

(49)

\[
\beta_0 \equiv H_0^2 R_0^2 \left( a_0^2 - kr^2 \right),
\]

(50)

the \( \tau \)-coordinate is expressed by the integral

\[
\tau = \sqrt{\frac{1}{a_0^2} \int dt \sqrt{\frac{a^2 - kr^2}{a_0^2 a^2 + \beta_0}}}
\]

(51)

where \( a = a(t) \).

3 Spatially flat FLRW universes

Motivated by modern cosmological observations, let us restrict to a spatially flat FLRW universe. For \( k = 0 \), the Gautreau-Hoffmann-like geodesic time reduces to

\[
\tau = \sqrt{\frac{1}{a_0^2} \int dt \sqrt{\frac{a^2}{a_0^2 a^2 + \beta_0}}}
\]

(52)

and it is sometimes possible to express it in terms of elementary functions. Below, we discuss these integrability situations.

3.1 Power-law scale factor

Let us consider first a power-law scale factor, which always occurs for a spatially flat FLRW universe dominated by a single perfect fluid with constant barotropic equation of state \( P = wP \).

\[
a(t) = a_0 t^p,
\]

(53)

\( ^\text{5} \text{Switching to conformal time does not help in computing this integral.} \)
where \( a_\ast \) is a constant. In this case, it is

\[
\tau = \sqrt{\alpha_0 a_\ast} \int dt t^p \left( \alpha_0 a_\ast^2 t^2 + \beta_0 \right)^{-1/2}.
\]

(54)

According to the Chebysev theorem of integration, the integral

\[
\int dt \ t^p (A + B t^r)^q
\]

(55)

where \( A, B, p, q, r \) are constants and \( r \neq 0, p, q, r \in \mathbb{Q} \), is expressed in terms of a finite number of elementary functions if and only if at least one of \( \frac{p+1}{r}, q, \frac{p+1}{r} + q \) is an integer \([26, 27]\).

An alternative approach consists of using a representation of the integral \([55]\) in terms of a hypergeometric series and noting that the assumptions of the Chebysev theorem are equivalent to the condition for this series to reduce to a finite sum (this equivalent condition was noted several times in the context of two-fluid cosmologies, for which the Friedmann equation reduces to an integral of the same type \([28, 29, 30, 31, 32]\)).

In our case we can assume \( p \in \mathbb{Q} \). In general, if the equation of state of the cosmic fluid has the barotropic form \( P = w \rho \) with \( w = \text{const.} \), then

\[
a(t) = a_\ast e^{\frac{r t}{w p}},
\]

(57)

and \( w \in \mathbb{Q} \) implies that \( p = 2/[3(w+1)] \in \mathbb{Q} \). Most values of the equation of state parameter \( w \) used in the cosmological literature are indeed rational but, if this is not the case, one can always approximate \( w \in \mathbb{R} \) with its rational approximation, still satisfying the cosmological observations to the required precision. We have then that \( p, r = 2p, q = -1/2 \in \mathbb{Q} \) and

\[
\frac{p+1}{r} = \frac{p+1}{2p}, \quad q = -\frac{1}{2} \notin \mathbb{Z}, \quad \frac{p+1}{r} + q = \frac{1}{2p};
\]

(58)

it is

\[
\frac{p+1}{r} = m \in \mathbb{Z}
\]

(59)

if and only if \( p = 1/(2m - 1) \), while

\[
\frac{p+1}{r} + q = m \in \mathbb{Z}
\]

(60)

if and only if \( p = 1/2m \), so at least one of \( (p+1)/r, q, (p+1)/r + q \in \mathbb{Z} \) if \( p = 1/n \), where \( n = \pm1, \pm2, \pm3, \ldots \). This list includes several well known equations of state in cosmology. Setting

\[
p = \frac{2}{3(w+1)}, \quad w_n = \frac{2n-3}{3},
\]

(61)

we have the equations of state listed in Table 1.

Let us discuss, as examples, two of these integrability cases, plus one not given by the Chebysev theorem.

### Table 1

| \( n \) | -1 | 1 | 2 | 3 | \ldots |
|---|---|---|---|---|---|
| \( w \) | -5/3 | -1/3 | 1/3 | 1 | \ldots |

#### 3.2 Radiation fluid

The equation of state and power-law rate of change associated with a \( k = 0 \) FLRW universe filled with radiation are \( P = \rho/3 \) and \( a(t) = a_\ast \sqrt{t} \), which give

\[
\tau = \sqrt{\alpha_0 a_\ast} \int dt \sqrt{t} \left( \alpha_0 a_\ast^2 t + \beta_0 \right)^{-1/2} = \frac{1}{\alpha_0 a_\ast^2} \left[ \sqrt{\alpha_0 a_\ast^2 t + \beta_0} \sqrt{\alpha_0 a_\ast^2 t} - \beta_0 \sinh^{-1} \left( \sqrt{\frac{\alpha_0 a_\ast^2 t}{\beta_0}} \right) \right].
\]

(62)

#### 3.3 Stiff fluid/free scalar field

A universe filled with a stiff fluid with equation of state \( P = \rho \) has scale factor \( a(t) = a_\ast t^{1/3} \), yielding

\[
\tau = \sqrt{\alpha_0 a_\ast} \int dt \ t^{1/3} \left[ \alpha_0 a_\ast^2 t^{2/3} + \beta_0 \right]^{-1/2} = \frac{1}{\alpha_0 a_\ast^{3/2}} \left( \alpha_0 a_\ast^2 t^{2/3} + 2 \beta_0 \right) \sqrt{\alpha_0 a_\ast^2 t^{2/3} + \beta_0}.
\]

(64)

#### 3.4 de Sitter space

The de Sitter universe with scale factor \( a(t) = a_\ast e^{H t} \), \( H = \text{const.} \) is another special case in which the Gautreau-Hoffmann-like geodesic time can be computed explicitly, giving

\[
\tau = \sqrt{\alpha_0 a_\ast} \int dt \ e^{H t} \left( \alpha_0 a_\ast^2 e^{2H t} + \beta_0 \right)^{-1/2} = \frac{1}{H} \tanh^{-1} \left( \frac{e^{H t}}{e^{2H t} + \frac{\beta_0}{\alpha_0 a_\ast^2}} \right).
\]

(66)

The relation \( \tau = \tau(t) \) can be inverted to find \( t(\tau) \) and \( a(\tau) \): from

\[
\frac{e^{H t}}{e^{2H t} + \frac{\beta_0}{\alpha_0 a_\ast^2}} = \tanh(H \tau)
\]

(67)

one obtains

\[
e^{2H t} \left[ 1 - \tanh^2(H \tau) \right] = \frac{\beta_0}{\alpha_0 a_\ast^2} \tanh^2(H \tau)
\]

(68)

\[\text{It is well known that a stiff fluid is equivalent to a free scalar field.}\]
and then
\[ e^{\nu} = \frac{\beta_0}{\alpha_0 a^2} \sinh (H \tau), \]
and taking the logarithm gives
\[ t = \frac{1}{H} \ln \left[ \frac{\beta_0}{\alpha_0 a^2} \sinh (H \tau) \right]. \]
The scale factor as a function of $\tau$ is then
\[ a(\tau) = \sqrt{\frac{\beta_0}{\alpha_0}} \sinh (H \tau). \]

3.5 Range of validity of the geodesic coordinates

Let us establish the range of validity of the Gautreau-Hoffmann-like geodesic coordinate patch. First, remember that the components of the four-velocity of radial geodesic observers are
\[ u' = \sqrt{\frac{\beta_0}{\alpha_0 a^2 (1 - kR^2/a^2^2)}} + 1, \]
\[ a^2 = H R \sqrt{\frac{\beta_0}{\alpha_0 a^2 (1 - kR^2/a^2^2)}} + 1 - \frac{1}{a} \sqrt{\frac{\beta_0}{\alpha_0}}, \]
with $\alpha_0$ and $\beta_0$ given by Eqs. 49 and 50. For a flat FLRW universe it is $1 - H_0^2 R_0^2 > 0$ and $\alpha_0 H_0 R_0 \geq 0$ for $R_0 < 1/H_0$, then the time component of the four-velocity is
\[ u' = \sqrt{\frac{\beta_0}{\alpha_0 a^2}} + 1, \]
which is defined only for $\beta_0 / (\alpha_0 a^2) > -1$. The radial component $\tilde{u}'$ of the four-velocity of a radial geodesic observer is defined only if $\alpha_0 > 0$, and one concludes that the geodesic coordinates must satisfy $R_0 < 1/H_0$.

For a curved ($k = \pm 1$) FLRW universe, $\alpha_0$ must be positive again, which is equivalent to the constraint
\[ 1 - R_0^2 \left( H_0^2 + \frac{k}{\alpha_0^2} \right) > 0 \]
or
\[ R_0 < \frac{1}{\sqrt{H_0^2 + k/\alpha_0^2}}, \]
where the right hand side is the radius of the apparent cosmological horizon [25]. If the universe is negatively curved, then
\[ \beta_0 = H_0^2 R_0^2 (\alpha_0^2 + R_0^2) > 0 \]
while, if it is positively curved,
\[ \beta_0 = H_0^2 R_0^2 (\alpha_0^2 - R_0^2) \geq 0 \]
for $R_0 \leq a_0$, which is always satisfied due to the constraint on $u'$. The latter gives
\[ \frac{\beta_0}{\alpha_0 a^2 (1 - kR^2/a^2^2)} > 0. \]

3.6 Line element in geodesic coordinates

Let us attempt to express the FLRW line element in Gautreau-Hoffmann-like geodesic coordinates. Eq. (75) can be used again to express $dt$ in terms of $d\tau$,
\[ dt = u' d\tau = \sqrt{\frac{\beta_0}{\alpha_0 a^2 (1 - kR^2/a^2^2)}} + 1 d\tau \]
which, substituted in the FLRW line element in pseudo- Painlevé-Gullstrand coordinates 26 produces the non-vanishing metric components
\[ g_{\tau \tau} = - \left( 1 - \frac{H^2 R^2}{1 - kR^2/a^2^2} \right) \left( \frac{\beta_0}{\alpha_0 a^2 (1 - kR^2/a^2^2)} + 1 \right), \]
\[ g_{\tau R} = - \frac{HR}{1 - kR^2/a^2^2} \sqrt{\frac{\beta_0}{\alpha_0 a^2 (1 - kR^2/a^2^2)}} + 1, \]
\[ g_{RR} = \frac{1}{1 - kR^2/a^2^2}, \]
\[ g_{\phi \phi} = R^2, \]
\[ g_{\theta \theta} = R^2 \sin^2 \theta, \]
in geodesic coordinates, where now $a = a(\tau(R))$ and $H = H(t(\tau))$. When $d\tau = 0$, the Riemannian 3-spaces are the same as in the comoving FLRW foliation.

Let us consider again the special case of the de Sitter universe. Its line element in geodesic coordinates can be diagonalized by introducing a new radial coordinate $\rho = \rho(\tau,R)$ by
\[ d\rho = \frac{1}{F} (\beta d\tau + dR), \]
where $\beta(\tau,R)$ must be determined a posteriori so that the cross-term $d\tau d\rho$ disappears, while $F(\tau,R)$ is an integrating factor satisfying
\[ \frac{\partial}{\partial R} \left( \frac{1}{F} \right) = \frac{\partial}{\partial \tau} \left( \frac{\beta}{F} \right) \]
in order to guarantee that $d\tau$ is an exact differential. Using $dR = F d\rho - \beta d\tau$, one obtains
\[ ds^2 = - \left[ (1 - H^2 R^2) \coth^2 (H \tau) \right] - \beta^2 - 2HR \coth (H \tau) \beta \right] d\tau^2 \]
\[ - 2F [HR \coth (H \tau) + \beta] d\rho d\tau + F^2 d\rho^2 + R^2 d\Omega^2, \]
The choice
\[ \beta = -HR\coth(H\tau) \] (91)
eliminates the time-radius cross-term and diagonalizes the line element, that becomes
\[ ds^2 = -\coth^2(H\tau)dt^2 + F^2d\rho^2 + R^2(T,\rho)d\Omega_2^2. \] (92)

With the choice (91) of \( \beta \), the general solution of Eq. (87) is
\[ F(\tau, R) = \frac{A\exp\left[-(\lambda/2)R^2\right]}{\tanh(H\tau)} [\cosh(H\tau)]^{\lambda/2}, \] (93)
where \( A \) is an integration constant and \( \lambda \) is a separation constant (see Appendix A). Setting \( \lambda = 1 \) and \( \lambda = 0 \) so that
\[ F(\tau, R) = \coth(H\tau) \] (94)
produces the diagonal de Sitter line element
\[ ds^2 = \coth^2(H\tau) \left( d\rho^2 - d\tau^2 \right) + R^2(T,\rho)d\Omega_2^2. \] (95)

4 Concluding remarks

We have revisited geodesic and quasi-geodesic observers in FLRW universes, removing the restrictions intrinsic in Gautreau’s previous work, which was limited to de Sitter and Einstein-de Sitter universes [15, 16]. In general, geodesic coordinates turn out to be rather cumbersome in generic FLRW spaces, especially those with curved spatial sections. In particular, one would like to express the geodesic time \( \tau \) as a function of the comoving time \( t \), the parameters, and the initial conditions along the radial timelike geodesics of FLRW space. The time measured by freely falling clocks (i.e., the proper time of radial geodesic massive observers) is expressed by an integral that, in general, cannot be computed explicitly in terms of elementary functions, even in spatially flat FLRW universes. This situation, however, improves in most situations of practical interest, including the case of a power-law scale factor and, of course, in de Sitter space. We have provided explicit solutions for a radiation fluid, a stiff fluid, and empty de Sitter space. The latter, being locally static, is rather similar to the Schwarzschild geometry and was already discussed by Gautreau [15], who had already used geodesic coordinates in Schwarzschild space in his earlier joint paper with Hoffmann [11]. For power-law scale factors \( a(t) \) in \( k = 0 \) FLRW universes, we have identified all the situations in which the geodesic time \( \tau \) can be expressed explicitly in terms of comoving time by making use of the Chebyshev theorem of integration [28, 29, 30, 31, 32], under the mild assumption that the equation of state parameter \( w \) is a rational number. Alternatively, one can use the representation of the integral [55] in terms of a hypergeometric function and note that the assumptions of the Chebyshev theorem leading to integrability are equivalent to the conditions for the truncation of the hypergeometric series to a finite sum (this mathematical condition was noted several times in the different context of two-fluid cosmologies [28, 29, 30, 31, 32]).

The range of validity of geodesic coordinates is also limited: the radial coordinate is restricted to the region below the apparent horizon of the FLRW universe and, therefore, it is not expected that geodesic coordinates will be useful for the thermodynamics of this apparent horizon since they cannot penetrate it (contrary to the Kruskal-Szekeres coordinates [33, 34], the Painlevé-Gullstrand coordinates [22, 23], or their Martel-Poisson generalization [24] in the Schwarzschild geometry). In this region below the apparent horizon, the geodesic coordinates describe the internal clock of dark matter or of free-falling test particles.

Appendix A: Integrating factor for the de Sitter universe

Using the variable \( u(\tau, R) \equiv 1/F \), we have
\[ \frac{\partial u}{\partial R} = \frac{\partial}{\partial \tau} \left[-HRu\coth(H\tau)\right]; \] (A.1)
assume the ansatz
\[ u(\tau, R) = T(\tau)S(R), \] (A.2)
then it is
\[ T \frac{dS}{dR} = -RS \frac{dT}{d\tau} \left[H\coth(H\tau)T\right]. \] (A.3)
Dividing both sides by \( RST \) gives
\[ \frac{1}{RS} \frac{dS}{dR} = \frac{1}{T} \frac{dT}{d\tau} \left[H\coth(H\tau)T\right]; \] (A.4)
the left-hand side depends only on \( R \) while the right-side depends only on \( \tau \), hence it must be
\[ \frac{1}{RS} \frac{dS}{dR} = \lambda = -\frac{1}{T} \frac{dT}{d\tau} \left[H\coth(H\tau)T\right], \] (A.5)
where \( \lambda \) is a separation constant. The function \( S(R) \) obeys
\[ \frac{1}{S} \frac{dS}{dR} = \lambda R, \] (A.6)
which integrates to
\[ \ln|S| = \frac{\lambda}{2} R^2 + C_1 \] (A.7)
(with \( C_1 \) an integration constant) and
\[ S = A_1 \exp \left(\frac{\lambda R^2}{2}\right). \] (A.8)
The time part \( T(\tau) \) satisfies the equation
\[ \frac{dT}{d\tau} \left[H\coth(H\tau)T\right] = -\lambda T, \] (A.9)
which yields
\[ H \coth (H \tau) \frac{dT}{d \tau} = - \left( \lambda + \frac{d}{d \tau} [H \coth (H \tau)] \right) T \]  
(A.10)

and
\[ \int \frac{dT}{T} = - \int \frac{\lambda \tau}{H \coth (H \tau)} - \int \frac{d [H \coth (H \tau)]}{H \coth (H \tau)}, \]  
(A.11)

giving
\[ T = \frac{A_2}{H} \tanh (H \tau) [\cosh (H \tau)]^{-\lambda / H^2}. \]  
(A.12)

The general solution for \( u(\tau, R) \) is, therefore,
\[ u(\tau, R) = \frac{A_1 A_2}{H} \exp \left( \frac{AR^2}{2} \right) \tanh (H \tau) [\cosh (H \tau)]^{-\lambda / H^2}. \]  
(A.13)

As \( A_{1,2} \) and \( H \) are constants, \( F(\tau, R) \) is of the form
\[ F(\tau, R) = A \exp \left[ - \left( \frac{\lambda}{2} R^2 \right) \right] \tanh (H \tau) [\cosh (H \tau)]^{\lambda / H^2}, \]  
(A.14)

where \( A \) is an integration constant.
