We present the results of our lattice QCD study of the hadronic matrix elements relevant to the physical radiative $J/\psi \to \eta_c \gamma$ and $h_c \to \eta_c \gamma$ decays. From computations with $N_f = 2$ dynamical quark in twisted mass QCD at four lattice spacings, we were able to take the continuum limit and obtained $\Gamma(J/\psi \to \eta_c \gamma) = 2.64(11)$ keV and $\Gamma(h_c \to \eta_c \gamma) = 0.72(5)$ MeV. We also computed the hyperfine splitting and found that it does not depend from the sea quark mass and we obtain $\Delta = m_{J/\psi} - m_{\eta_c} = 112 \pm 4$ MeV.

1. Introduction

The radiative decay of \( J/\psi \to \eta_c \gamma \) has been subject of extensive theoretical and experimental studies since many years. The current experimental results quoted by PDG \([1]\) is,

\[
\Gamma(J/\psi \to \eta_c \gamma) = 1.58(37) \text{ keV}. \tag{1.1}
\]

This value is obtained after averaging two experimental results, namely \( \Gamma(J/\psi \to \eta_c \gamma) = 1.18(33) \text{ keV} \) by Crystal Ball \([3]\), and the more recent value obtained by CLEOc 1.91(28)(3) keV \([3]\). The currently running KEDR experiment \([4]\) instead suggests a larger value, 2.2(6) keV. It is fair to say that the current experimental situation is unclear and dedicated charm experiment at BESIII is expected to clarify the situation.

Prior to 2012 the theoretical situation concerning prediction of \( \Gamma(J/\psi \to \eta_c \gamma) \) was not better. Dispersive analysis of \( \Gamma(\eta_c \to 2\gamma) \) obtained an upper bound for the width \( \Gamma(J/\psi \to \eta_c \gamma) < 3.2 \text{ keV} \) \([5]\). Two different QCD sum rule calculations resulted in \((1.7 \pm 0.4) \text{ keV}\) \([6]\) and \((2.6 \pm 0.5) \text{ keV}\) \([7]\). An effective theory of non relativistic QCD found \((1.5 \pm 1.0) \text{ keV}\) \([8]\). Lastly, two different potential quark model calculations exist, predicting an even larger value for the decay width, 3.3 keV \([9]\), and 2.85 keV \([10]\). To all of these predictions the error must be regarded not as an estimate of uncertainty intrinsic to the method, but only as susceptibility of the method to the variation of external parameters entering the prediction. The global picture of the theoretical predictions for the \( \Gamma(J/\psi \to \eta_c \gamma) \) is puzzling and inconclusive, and necessitates a fully non perturbative analysis from the first principles of QCD.

The first extensive study of the radiative decays of charmonia on the lattice has been reported in ref. \([11]\), where the authors computed relevant matrix elements for a number of decay channels in the quenched approximation of QCD and with one lattice spacing only. That computation has been extended to the case of \( N_f = 2 \) dynamical light quark flavors at single lattice spacing in ref. \([12]\). In this paper we will focus on \( J/\psi \to \eta_c \gamma \) and \( h_c \to \eta_c \gamma \), for which we compute the desired form factors for four lattice spacings that we could extrapolate to the continuum limit. Our result for \( \Gamma(J/\psi \to \eta_c \gamma) \) allow for a clear comparison between theory and experiment, as soon as the results from KEDR and BESIII become available. Our \( \Gamma(h_c \to \eta_c \gamma) \) will provide us with a prediction for \( h_c \) lifetime, and both could be compared with experimental measure when it becomes available.

This presentation is based on our recent paper \([13]\) where the interested reader can find details of all the numerically computed data entering our calculation.

2. Hadronic Matrix Elements

The transition matrix element responsible for the \( J/\psi \to \eta_c \gamma^* \) decay reads,

\[
\langle \eta_c(k)|J_{\mu}^{em}|J/\psi(p, \epsilon_{\lambda}) \rangle = e \mathcal{D}_{c} \epsilon_{\nu a b} \epsilon^{a}_{\lambda} p^\beta k^\nu \frac{2 V(q^2)}{(m_{J/\psi} + m_{\eta_c})}, \tag{2.1}
\]

where \( J_{\mu}^{em} = \mathcal{D}_{c} \bar{c} \gamma_{\mu} c \) is the relevant piece of the electromagnetic current, with \( \mathcal{D}_{c} = 2/3 \) in units of \( e = \sqrt{4\pi \alpha_{em}} \). Information regarding the non-perturbative QCD dynamics is encoded in the form factor \( V(q^2) \) and represents the most challenging part on the theory side. For the physical process,

Radiative decays of charmonia on the lattice

\( \Gamma(J/\psi \rightarrow \eta_c \gamma) = \frac{8}{27} \alpha_{em} (m_{J/\psi} + m_{\eta_c}) \left( \frac{\Delta}{m_{J/\psi}} \right)^2 |V(0)|^2, \quad \Delta = m_{J/\psi} - m_{\eta_c}. \) \tag{2.2}

Similarly \( h_c \rightarrow \eta_c \gamma \) transition matrix element is parametrized by two form factors \( F_{1,2}(q^2), \)

\[ \frac{\langle \eta_c(k)|J_{\mu}^{em}|h_c(p, \epsilon_{\lambda}) \rangle}{ie D_c} = m_{h_c} F_1(q^2) \left( \epsilon_{\mu}^{\lambda*} - \frac{\epsilon_{\mu}^{\lambda} q}{q^2} q_{\mu} \right) + F_2(q^2)(\epsilon_{\lambda}^{\mu*} q) \left[ \frac{m_{h_c}^2 - m_{\eta_c}^2}{q^2} q_{\mu} - (p + k)_{\mu} \right] \] \tag{2.3}

The decay rate for the on-shell photon is [11]

\[ \Gamma(h_c \rightarrow \eta_c \gamma) = 8\alpha_{em}(m_{h_c}^2 - m_{\eta_c}^2) |F_1(0)|^2 / (27m_{\eta_c}^2). \] \tag{2.4}

We can compute the form factor \( V(q^2) \) and \( F_1(q^2) \) directly at \( q^2 = 0 \) by using twisted boundary conditions [14] on one propagator, which will be labelled in the following by a superscript “\( \theta \)”.

3. Two-point correlation functions

As in [5], we use the maximally twisted mass QCD [6] gauge field configurations produced by ETM collaboration [17]. We extract mass of charmonia from the two point correlation functions:

\[ C^\Gamma(t) = \sum_i \text{Tr} \left[ O^\Gamma(\vec{0},0) O^\Gamma(x,t) \right], \quad O^\Gamma(x) = \overline{c}(x) \Gamma c(x), \] \tag{3.1}

in which the Dirac structures \( \Gamma \) are chosen as \( \gamma_5, \gamma_i, \sigma_{ij}, i \in (1,2,3) \) to provide the coupling to the charmonium states with quantum numbers \( J^{PC} = 0^{-+}, 1^{--}, \) and \( 1^{++} \), for \( \eta_c, J/\psi \) and \( h_c \), respectively. We implement the Gaussian smearing on the fermionic fields \( c \) entering [5,1] and compute the quark propagators using stochastic techniques [17]. Charm quark mass, \( \mu_c \), at each of our lattices has been fixed according to the result of ref. [18] where it was shown that the charm quark computed from the comparison of the lattice results with the physical \( m_{\eta_c} \) fully agrees with the value obtained by using the physical \( m_{D_s} \) or \( m_{D} \). Therefore, we can say that \( m_{\eta_c} \) obtained by computing the effective mass \( m_{\eta_c}^{\text{eff}} \) from correlation function \( C^\Gamma(t) \), and then by fitting \( m_{\eta_c}^{\text{eff}}(t) \) at large time separations to a constant, is merely a verification that, after a smooth continuum extrapolation, we indeed reproduce \( m_{\eta_c}^{\text{exp}} = 2.980(1) \) GeV. To extract the values of \( m_{J/\psi} \) and \( m_{h_c} \) we proceed along the same line, computing \( m_{J/\psi,h_c}^{\text{eff}}(t) \) using the appropriate correlation function, and then fitting them at sufficiently large time separation.

In fig. [6] we show an example of two effective mass plots, as obtained by using all four lattice spacings explored in this work and for one value of the sea quark mass, which we choose to be the least light ones, for the case of \( \eta_c \) and of \( h_c \) mesons. We see that the effective masses for the pseudoscalar are excellent while the signal for \( h_c \) is good but more noisy. The quality in the case of \( J/\psi \) (not shown) lies between the two illustrated. The effective masses are then combined to

\[ R_{J/\psi}(t) = \frac{m_{J/\psi}^{\text{eff}}(t)}{m_{\eta_c}^{\text{eff}}(t)}, \quad R_{h_c}(t) = \frac{m_{h_c}^{\text{eff}}(t)}{m_{\eta_c}^{\text{eff}}(t)}. \] \tag{3.2}
We then fit $R_{J/\psi,\eta_c}(t)$ plateaus to a constant $R_{J/\psi,\eta_c}$, extrapolating to the continuum limit, we get

$$R_{J/\psi,\eta_c} = R_{J/\psi,\eta_c}^{\text{cont.}} \left[ 1 + b_{J/\psi,\eta_c} m_q + c_{J/\psi,\eta_c} a^2 / a_{\beta=3.9}^2 \right],$$  

(3.3)

$$R_{J/\psi} = 1.0377(6) \ [1.0391(4)]^{\text{exp.}}, \quad R_{\eta_c}^{\text{cont.}} = 1.187(11) \ [1.1829(5)]^{\text{exp.}}.$$  

(3.4)

In eq. (3.3) the parameter $b_{J/\psi,\eta_c} \approx 0$ measures the dependence on the sea quark mass, $m_q \equiv m_q^\text{MS}(2 \text{ GeV})$, while the parameter $c_{J/\psi,\eta_c} \approx 3\%$ measures the leading discretization effects. Division by $a_{\beta=3.9} = 0.086 \text{ fm}$ is made for convenience. The linear fit (3.3) describes our data very well except for the results obtained at $\beta = 3.8$, that can be either excluded from the extrapolation (above results), or included adding a term proportional to $a^4$, leading to a fully consistent result with the one quoted above. Having neglected the disconnected contributions to the correlation functions, the fact that our lattice results agree with the experimental values (3.4) can be viewed as a verification that they are indeed very small.

From eq. (3.4), one can infer the hyperfine splitting:

$$\Delta = m_{J/\psi} - m_{\eta_c} = m_{\eta_c} (R_{J/\psi} - 1),$$  

(3.5)

which after linear fit to a parameterization similar to that of eq. (3.3) gives

$$\Delta^{\text{cont.}} = (112 \pm 4) \text{ MeV} \ [116.6 \pm 1.2]^{\text{PDG.}},$$  

(3.6)

in good agreement with the experimental result written in brackets [1], and in excellent agreement with the result of BESIII [19], $\Delta = (112.4 \pm 1.16) \text{ MeV}$. Note also that from the fit of our data we
find $\Delta = 1.0(3)$ GeV$^{-1}$, in qualitative agreement with ref. [20] where a tiny decrease of $\Delta$ is found while lowering the sea quark mass. Note, however, that this observation ($h_\Delta \gtrapprox 0$) disagrees with earlier findings of ref. [21].

4. Radiative Transition Form Factors

To extract the desired hadronic matrix element (2.1) we computed the three point correlators

$$C_{ij}(\vec{q},t) = \sum_{x,y} \langle V_i(x) J_j^{em}(y) \rangle e^{i\vec{q} \cdot (x-y)} = \sum_{x,y} \langle \text{Tr} \left[ S_c(y;0) \gamma_i S_c(0,x) \gamma_j S_c^\theta(x,y) \gamma_5 \right] \rangle ,$$

(4.1)

where

$$P = \bar{c} \gamma c, \quad V_i = \bar{c} \gamma_i c$$

are the interpolating operators fixed at $t = 0$ and $t = t_v = T/2$ ($T$ being the time extension of our lattices). Using the fact that our three-momentum $\vec{q} = \hat{\theta}/L$ is isotropic, we averaging 6 equivalent contributions, $C_{12}, C_{23}, C_{31}, -C_{21}, -C_{32}, -C_{13}$ to $C_V$,

$$C_V(\vec{q};t) = \frac{2S^S}{2E_{\eta_c}^S} \frac{\theta_0}{L} \frac{e^{-\left[E_{\eta_c}+(m_{J/\psi}-E_{\eta_c})t\right]}}{m_{J/\psi}+m_{\eta_c}} V(0) ,$$

(4.2)

where the last expression is valid for sufficiently separated operators in the correlation function (4.1). By renormalizing the local electromagnetic current and combining appropriately two and three points correlators, we can build a ratio $R_{J/\psi}$ where we eliminate the source terms, obtaining $V(0)$ from a fit to a constant as shown in fig. [2].

Extrapolation the physical limit ($m_{\text{sea}} \equiv m_q \to 0, a \to 0$) is performed using a form similar to eq.(3.3). We do not observe any dependence of $V(0)$ on the light sea quark mass. Instead the discretization effects are rather large, with $c_V = -23\%$. Our final result is:

$$V(0) = 1.94(4) .$$

(4.3)

We now turn to the discussion of the form factor $F_1(0)$, relevant to the $h_c \to \eta_c \gamma$ decay, as defined...
in eq. (2.3). To that end we compute the three point correlators

\[
C_{ijk}(\vec{q};t) = \sum_{i,j} \langle T_{ij}^\dagger(0) j_{k}^\text{em}(x) P(y) \rangle e^{i\vec{q} \cdot (\vec{x} - \vec{y})} = -\langle \sum_{i,j} \text{Tr} \left[ S_c(y;0) \gamma_i \gamma_j S_c(0,x) \gamma_k \gamma_5 S_c(0,y) \gamma_5 \theta^5(x,y) \gamma_5 \right] \rangle. \tag{4.4}
\]

\(F_1(0)\) is then obtained fitting to a constant the ratio obtained dividing the combination

\[
C_{F_1} = \frac{C_{123} + C_{231} + C_{312}}{3} - \frac{C_{131} + C_{212} + C_{323} + C_{232} + C_{313} + C_{121}}{6}
\]

with the two point functions (see fig. 3). We perform the continuum and chiral extrapolations, in a way analogous to eq. (3.3). Again, the form factor \(F_1(0)\) is insensitive to the variation of the light sea quark mass. Contrary to \(V(0)\), the discretization effects turn out to be smaller: we find \(c_{F_1} \approx 2\%\), and our final results is

\[
F_1(0) = -0.57(2). \tag{4.5}
\]

5. Phenomenology

5.1 Decays of \(J/\psi\)

Concerning the radiative decay \(J/\psi \rightarrow \eta_c \gamma\), by inserting our value (4.3) in eq. (2.2) we get

\[
\Gamma(J/\psi \rightarrow \eta_c \gamma) = 2.64(11) \text{ keV} \quad [1.58(37) \text{ keV}]^{\exp}; \tag{5.1}
\]

where we used the measured \(\text{Br}(J/\psi \rightarrow \eta_c \gamma) = (1.7 \pm 0.4)\%\), the full width \(\Gamma_{J/\psi} = 92.9 \pm 2.8 \text{ keV}\) \[\text{I}\], the physical values of \(m_{J/\psi} = 3096.92(1) \text{ MeV}\) and \(\Delta = 116.6 \pm 1.2 \text{ MeV}\).

Our result for the decay rate is larger than the experimental one, and the agreement is only at 2\(\sigma\). The various effective approaches presented in the introduction agree with ours too, except that we have smaller and controlled uncertainty. We hope more effort on the experimental side will be devoted to clarify the disagreement among various experiments.
5.2 $h_c \rightarrow \eta_c \gamma$

$h_c$ escaped the experimental detection for a long time and only recently CLEO succeeded to isolate this state \[23\] and observed that its prominent mode is precisely $h_c \rightarrow \eta_c \gamma$, the branching fraction of which was later accurately measured at the BESIII experiment, with a result: $\text{Br}(h_c \rightarrow \eta_c \gamma) = (53 \pm 7)\%$. \[19\]. We obviously cannot compute the branching ratio on the lattice, but with our form factor result (4.5) we can compute the decay width using eq. (2.4). We get

$$\Gamma(h_c \rightarrow \eta_c \gamma) = 0.72(5) \text{ MeV}. \quad (5.2)$$

This can be combined with the measured $\text{Br}(h_c \rightarrow \eta_c \gamma)$ to estimate the width of $h_c$. We obtain:

$$\Gamma_{h_c} = \frac{\Gamma(h_c \rightarrow \eta_c \gamma)}{\text{Br}(h_c \rightarrow \eta_c \gamma)} = 1.37 \pm 0.11 \pm 0.18 \text{ MeV} = 1.37 \pm 0.22 \text{ MeV}, \quad (5.3)$$

where the first error comes from our determination of the form factor $F_1(0)$, and the second one reflects the experimental uncertainty in the branching ratio. This constitutes a prediction that will be interesting to check against experiment once the latter becomes available.

To compare with other lattice results we convert the value reported in ref. \[11\] to our dimensionless form factor and obtain $F_1(0) = -0.53(3)$, which agrees very well with our result. Similar conversion of the result of ref. \[12\] would result in $F_1(0) = -0.33(1)$, much smaller value than ours, whether we compare it with the values we obtain at $\beta = 4.05$ or the one in the continuum.
6. Summary and future perspectives

We presented results of our analysis of the radiative decays of charmonia by means of QCD simulations on the lattice. Using several lattice spacings of twisted mass QCD with $N_f = 2$ dynamical flavors we were able to extrapolate the relevant form factors to the continuum limit.

We emphasize that our results are obtained without inclusion of disconnected diagrams.

Acknowledgments

Computations are performed using GENCI (CINES) Grant 2012-056806.
