We put forward a gauge-invariant theoretical framework for studying time-resolved thermoelectric transport in an arbitrary multiterminal electronic quantum system described by a non-interacting tight-binding model. The system is driven out of equilibrium by an external time-dependent electromagnetic field (switched on at time $t_0$) and possibly by static temperature or electrochemical potential biases applied (from the remote past) between the electronic reservoirs. Numerical simulations are conducted by extending to energy transport the wave-function approach developed by Gaury et al. and implemented in the t-Kwant library. We provide a module that allows us to compute the time-resolved heat currents and powers in addition to the (already implemented) charge currents, and thus to simulate dynamical thermoelectric transport through realistic devices, when electron-electron and electron-phonon interactions can be neglected. We apply our method to the non-interacting Resonant Level Model and verify that we recover the results reported in the literature for the time-resolved heat currents in the expected limits. Finally, we showcase the versatility of the library by simulating dynamical thermal transport in a Quantum Point Contact subjected to voltage pulses.

I. INTRODUCTION

Since its early stages in the sixties, research in time-dependent quantum nanoelectronics has predominantly focused on charge transport. Milestone achievements in the AC regime include e.g. the realization of electron pumps, the measurement of the relaxation times of RC and LC quantum circuits, the observation of radiative signatures of dynamical Coulomb Blockade and the dynamical measurement of the fractional charge of anyons. In the last decade, the experimental realization of single-electron sources has opened up a new research avenue in time-dependent nanoelectronics with potential applications to quantum computing. On the theory side, the usual frameworks to handle time-dependent transport in quantum electronic systems are the Non Equilibrium Green’s Function (NEGF) approach and the time-dependent scattering formalism, combined with the Floquet theory for time-periodic perturbations. In practice, the NEGF equations are extremely difficult to integrate, even numerically, so that alternative computational strategies have been developed. In particular, a novel wave-function based approach implemented in the t-Kwant library has recently made possible the simulation of time-resolved quantum transport in realistic mesoscopic devices.

Dynamical charge transport has thus been the subject of an intense experimental and theoretical activity in the last decades. In comparison, the study of energy and heat transport in time-dependent quantum electron systems is an emerging research topic. Experimental investigations in the field are challenging and currently at their infancy. A breakthrough has been achieved recently by Karimi et al. with the measurement of heat and temperature fluctuations in superconducting quantum circuits. Nevertheless, the literature in the field is largely dominated by theoretical works, in particular those studying mesoscopic systems with periodic driving. They can be roughly ranged into three categories: A first one investigating the fundamentals of quantum thermodynamics, a second one assessing the applicative potential of high-frequency nanoelectronics for AC-driven thermoelectric, heat pumping, or Josephson-effect-based refrigeration, and a third one analyzing energy current and noise as new probes of mesoscopic electron systems. From a technical point of view, a wide range of approaches have been pursued to deal with dynamical energy and heat transport in mesoscopic electron systems subjected to time-dependent bias and gate voltages, e.g. the Floquet theory in the AC regime, the master equation approach often assuming slow driving and weak system-reservoir coupling, the well-established (but cumbersome) NEGF technique, and more recently the wave-function and the auxiliary-mode approaches. The effect of Coulomb interaction has been included within different frameworks, near the adiabatic regime and beyond, interestingly, alternative methods have also been developed to describe transient particle and heat currents in response to the application of a temperature gradient. However, to date, the different methods listed above have only been applied to paradigmatic systems ranging mostly from the single site Resonant Level Model (RLM) to the one-dimensional chain.

In addition to the technical difficulty of solving the time-dependent quantum problem, the study of energy transport and conversion in open electronic quantum systems driven by time-dependent potentials is hindered by fundamental issues about the non-equilibrium thermodynamical description of such systems. In particular, the question of the proper definition of a time-dependent heat current (in consistency with thermodynamic requirements) is still under debate. A major difficulty arises from the ill-defined splitting between...
the central system and the electronic reservoirs in the strong coupling regime. Using the time-dependent RLM as a prototypical model, it was argued in Refs.\textsuperscript{63}\textsuperscript{73} that half of the contribution coming from the energy stored in the system-reservoir coupling region should be included in the definition of the heat current flowing into a given reservoir. This result, derived in the case where the time dependence is restricted to the central region, was later questioned in Refs.\textsuperscript{61}\textsuperscript{74} when the system-reservoir coupling is also made time-dependent. It was finally generalized to the case of time-dependent coupling by the inclusion of an extra term in the heat current definition.\textsuperscript{62}\textsuperscript{74}\textsuperscript{82} Recently, Bruch \textit{et al.}\textsuperscript{63} developed an alternative approach based on the Landauer-Büttiker scattering theory that circumvents the problem of the system-reservoir splitting.

In the present manuscript, we put forward a general framework for the simulation of time-resolved thermoelectric transport in realistic mesoscopic devices subjected to external time-dependent electromagnetic fields. The system under consideration is made of an arbitrary (non-interacting) electron scattering region coupled through ideal (non-interacting) leads to electronic reservoirs at local equilibrium. Spin is not included. Till a given time \( t_0 \), the tight-binding Hamiltonian describing the system is considered as time-independent but the system is possibly driven in an non-equilibrium steady-state by the application of (static) electrochemical potential or temperature gradients between the reservoirs. After \( t_0 \), an external time-dependent electromagnetic field is applied. It may account for the presence of voltage pulses in the leads, time-varying electrostatic gates in the vicinity of the electron gas, or time-dependent magnetic fields in the scattering region. Our first task consists in building a thermoelectric framework that involves quantities (particle, energy, and power densities, particle and energy currents) that are all invariant under an arbitrary gauge transformation of the external electromagnetic field. For that purpose, we follow Refs.\textsuperscript{62}\textsuperscript{63} and define an energy operator that differs in general from the Hamiltonian operator, since the expectation value of the Hamiltonian is generally not gauge invariant. Secondly, to compute the different quantities numerically in an efficient way, we leverage the wave-function approach developed in Refs.\textsuperscript{25}\textsuperscript{27} for the simulation of time-dependent quantum transport. Till recently,\textsuperscript{63} this approach had only been considered within the context of charge transport.\textsuperscript{29}\textsuperscript{33} Its generalization to energy transport was addressed in Ref.\textsuperscript{63} for the study of a molecular network model. Here, we formulate a general gauge-invariant framework for simulating time-dependent thermoelectric transport in an arbitrary (non-interacting) electron system. We report on its practical implementation as a thermoelectric extension of the t-Kwant simulation library, discuss how it converges to the usual Landauer-Büttiker approach in the static limit, and check the validity of our approach by using the Resonant Level Model (RLM) as a testbed. A short investigation of time-dependent heat transport in a Quantum Point Contact (QPC) is also provided for illustrating the potential of our t-Kwant based numerical tool. However, little emphasis is put in this article on physical interpretations for specific examples. This is left for future works. Our approach which inherits the benefits of t-Kwant brings within reach the simulation of time-resolved heat and thermoelectric transport in large realistic systems. It can handle arbitrary time-dependent perturbations, beyond the single-frequency AC limit and the adiabatic regime. Moreover, it does not rely on the wide-band limit hypothesis which is commonly assumed in works using the NEGF technique.

The outline of the paper is as follows. We define our general non-interacting and time-dependent tight-binding model in Sec.\textsuperscript{II}. Then in Sec.\textsuperscript{III} we draw up a gauge-invariant thermoelectric framework in terms of the lesser Green’s function of the system. The numerical method used to calculate the time-dependent (particle, energy, and heat) currents as well as the time-dependent powers is introduced in Sec.\textsuperscript{IV}. It is based on the wavefunction approach developed in Refs.\textsuperscript{25}\textsuperscript{27} which draws upon a reformulation of the NEGF equations in terms of the time-dependent scattering states. We review briefly the approach and explain how to use it for energy transport. In Sec.\textsuperscript{V} we apply our method to the Resonant Level (toy) Model and benchmark our results against the ones obtained with other techniques in previous works. We show that we reproduce the NEGF results in the wide-band limit and the results of Ref.\textsuperscript{63} beyond this limit. Finally in Sec.\textsuperscript{VI} we demonstrate the feasibility of large scale simulations by computing time-dependent heat currents in a QPC subjected to a temperature gradient and to a voltage pulse. We conclude in Sec.\textsuperscript{VII} and discuss briefly possible continuations of this work.

II. TIGHT-BINDING MODEL

We model noninteracting spinless electrons in an open system made of a scattering region \( \mathcal{S} \) connected to an arbitrary number \( M \) of semi-infinite leads \( \mathcal{L}_\alpha \) (\( \alpha = 1 \) to \( M \)). The system is discretized on a lattice (with lattice spacing \( a = 1 \)) and from the remote past till a given time \( t_0 \), it is described by the general quadratic Hamiltonian

\[
\hat{H}(t \leq t_0) = \hat{H}^0 = \sum_{i,j} H_{ij}^0 \hat{c}_i^\dagger \hat{c}_j
\]

\( \hat{c}_i^\dagger \) [resp. \( \hat{c}_i \)] being the creation [resp. annihilation] operator of an electron on site \( i \) at position \( r_i \). The leads have a translation-invariant structure made up of an infinite repetition of interconnected identical unit cells and hopping terms between two different leads are set to zero. Importantly, the couplings between the (first cell of the) leads and the scattering region is included in the static Hamiltonian \( \hat{H}^0 \). For this reason, our approach is similar to the so-called partition-free approach.\textsuperscript{109}\textsuperscript{110}\textsuperscript{115} \( \hat{H}^0 \) also accounts for the presence of any static electromagnetic
fields due e.g. to surrounding metallic gates or to the application of voltage biases between leads. Finally, each lead $\mathcal{L}_\alpha$ is attached to a reservoir in thermodynamic equilibrium characterized by an electrochemical potential $\mu_\alpha$ and a temperature $T_r$.

For times $t$ larger than $t_0$, an external time-dependent electromagnetic field is applied

$$E(r, t) = -\nabla V(r, t) - \frac{\partial A}{\partial t}(r, t) \quad (2a)$$
$$B(r, t) = \nabla \times A(r, t) \quad (2b)$$

$V(r, t)$ and $A(r, t)$ being the electromagnetic scalar and vector potentials at position $r$ at time $t$. The system Hamiltonian becomes

$$\hat{H}(t > t_0) = \sum_{i,j} H_{ij}(t) \hat{c}_i^\dagger \hat{c}_j$$

(3)

with

$$H_{ij}(t) = H_{ij}^0 + H_{ij}^t(t). \quad (4)$$

The Hamiltonian $\hat{H}(t) = \sum_{i,j} H_{ij}(t) \hat{c}_i^\dagger \hat{c}_j$ accounts for the presence of the external time-dependent electromagnetic field when $t > t_0$. In the scattering region, the field may be fully arbitrary and we have

$$H_{ij}^t(t) = eV_i(t)\delta_{ij} + H_{ij}^0(e^{i\phi_{ij}(t)} - 1)(1 - \delta_{ij}) \quad (5)$$

where $i$ and $j$ both lie in $\mathcal{S}$ (or one of them lies in the first cell of one lead). In Eq. (5), $e$ denotes the electron charge, $V_i(t) = V(r_i, t)$ and $\phi_{ij}(t) = (e/\hbar) \int_{r_i}^{r_j} A(r, t) \cdot dr$ is a Peierls phase accounting for $B(r, t)$. In the leads $\mathcal{L}_\alpha$, no time-dependent magnetic fields but only homogeneous time-dependent electric potentials $V_i(t) = V_\alpha(t)$ are supposed to be applied so that

$$H_{ij}^t(t) = eV_\alpha(t)\delta_{ij} \quad (i \in \mathcal{L}_\alpha, j \in \mathcal{L}_\alpha). \quad (6)$$

If needed, the abrupt drop of $V_i(t)$ at the interface between the leads and the scattering region $\mathcal{S}$ can be easily absorbed by including the first cells of the leads into $\mathcal{S}$ and by defining an effective screened potential $V_i(t)$ in the vicinity of the interface. Besides, in an actual device, a time-dependent voltage source may induce a variation of the chemical potential in the electronic reservoir, in addition to a variation of the electric potential. This case is not handled in the present paper as it would require modeling relaxation inside the reservoirs. Yet a qualitative discussion of the role of the electrostatics in realistic devices (reported in Sec.8.4.4 of Ref.28) shows that the above model has broad applicability in the field of time-dependent quantum nanoelectronics.

III. GAUGE-INvariant TIME-RESOLVED THERMOELECTRIC FRAMEWORK

Here we construct the theoretical framework that will be used to describe time-dependent thermoelectric transport in the generic tight-binding model defined above.

Our aim is to formulate a theory that is invariant under any gauge transformation of the external electromagnetic field. For that purpose, we follow Refs.29 and define an energy operator that differs in general from the Hamiltonian operator. We start this section with a succinct reminder of gauge invariance in quantum mechanics, then we draw our theoretical picture of time-dependent thermoelectrics from the local to the global scale.

A. Gauge transformations

We consider an arbitrary local gauge transformation of the electromagnetic field

$$V(r_i, t) \rightarrow \tilde{V}(r_i, t) = V(r_i, t) - \frac{\partial \Lambda(r_i, t)}{\partial t} \quad (7a)$$
$$A(r_i, t) \rightarrow \tilde{A}(r_i, t) = A(r_i, t) + \nabla \Lambda(r_i, t) \quad (7b)$$

where $\Lambda(r_i, t)$ is an arbitrary, differentiable, real function of space and time. Under Eq. (7), the Hamiltonian $\hat{H}(t)$ transforms as

$$\hat{H}(t) \rightarrow \tilde{\hat{H}}(t) = \sum_{i,j} \tilde{H}_{ij}(t) \hat{c}_i^\dagger \hat{c}_j \quad (8)$$

where

$$\tilde{H}_{ii}(t) = H_{ii}(t) - e \frac{\partial \Lambda_i(t)}{\partial t} \quad (9a)$$
$$\tilde{H}_{ij}(t) = H_{ij}(t)e^{i\frac{\pi}{2}[\Lambda_i(t)-\Lambda_j(t)]} \quad (9b)$$

and $\Lambda_i(t) = \Lambda(r_i, t)$. In particular, for $t \leq t_0$ when $V(r_i, t) = 0$ and $A(r_i, t) = 0$, the gauge-transformed static Hamiltonian $\tilde{\hat{H}}(t \leq t_0) = \tilde{\hat{H}}^0$ may become artificially time-dependent. In the rest of the manuscript, we fix the gauge when $t \leq t_0$ and no time-dependent electromagnetic field is applied. We choose the natural gauge in which $\Lambda_i(t \leq t_0) = 0$.

The electromagnetic gauge transformation (7) can also be understood as a change of basis of the one-body orbitals on sites $i$ associated to the operators $\hat{c}_i$. Under Eq. (7) a unitary transformation $\hat{U}(t) = \exp\left(i\frac{\pi}{2} \sum_i \Lambda_i(t) \hat{c}_i^\dagger \hat{c}_i \right)$ is made on the annihilation operator

$$\hat{c}_i \rightarrow \tilde{\hat{c}}_i = \hat{U} \hat{c}_i \hat{U}^\dagger = e^{-i\frac{\pi}{2} \Lambda_i(t)} \hat{c}_i \quad (10)$$

so that the transformed Hamiltonian $\tilde{\hat{H}}$ can be written as

$$\tilde{\hat{H}} = \hat{U} \hat{H} \hat{U}^\dagger - i\hbar \hat{U} \frac{\partial \hat{U}^\dagger}{\partial t} \quad (11)$$

after having noticed that

$$i\hbar \frac{\partial \hat{U}^\dagger}{\partial t} = e \sum_i \frac{\partial \Lambda_i}{\partial t} \hat{c}_i^\dagger \hat{c}_i = e \sum_i (V_i - \tilde{V}_i) \hat{c}_i^\dagger \hat{c}_i \quad (12)$$
The Schrödinger equation
\[
\hbar \frac{\partial |\Psi(t)\rangle}{\partial t} = \hat{H}(t)|\Psi(t)\rangle
\] (13)
written here for an arbitrary solution $|\Psi(t)\rangle$, turns out to be invariant in form under the local gauge transformation [7]
\[
\hat{\Omega} \rightarrow \hat{\Omega} = \hat{U}\hat{\Omega}\hat{U}^\dagger
\] (16)
under Eq. [7] has a gauge invariant expectation value
\[
\langle \Psi|\hat{\Omega}|\Psi\rangle = \langle \hat{\Omega}|\hat{\Omega}|\hat{\Omega}|\Psi\rangle
\] (17)
the Hamiltonian does not (see Eq. [11]): its expectation value is in general not gauge invariant
\[
\langle \Psi|\hat{H}|\Psi\rangle \neq \langle \hat{\Omega}|\hat{H}|\hat{\Omega}|\Psi\rangle
\] (18)
and thus it cannot be considered as the energy operator [22].

B. Local quantities

In this section, we define the energy density and the local energy current carried by electrons inside the scattering region. We also derive the related continuity equation. It involves the local power injected in the system by the time-dependent external electromagnetic field. The different quantities are constructed following Refs. [22,23] so as to be gauge invariant. They are formally written in terms of the lesser Green’s function of the system. The continuity equation for the electron density is also recalled for completeness.

1. Particle density and local particle current

We introduce the lesser Green’s function
\[
G_{ij}^c(t,t') = \frac{i}{\hbar} \langle c_i(t')\hat{c}_j(t)\rangle
\] (19)
where $\hat{c}_i(t)$ is the annihilation operator in the Heisenberg representation. The change over time of the electron density
\[
\rho_i^N(t) = \langle \hat{c}_i(t)\hat{c}_i(t)\rangle = -i\hbar G_{ii}^c(t,t)
\] (20)
can be calculated by using the equation of motion
\[
\frac{d\hat{O}_N}{dt} = \frac{\partial \hat{O}_N}{\partial t}\bigg|_H + i\frac{\hbar}{2}[\hat{H}_N,\hat{O}_N]
\] (21)
here written for an arbitrary operator $\hat{O}$. $\hat{O}_N$ and $\hat{H}_N = \sum_{i,j} H_{ij}(t)\hat{c}_i(t)\hat{c}_j(t)$ correspond to $\hat{O}$ and $\hat{H}$ in the Heisenberg representation. The subscript $\mathcal{H}$ will be dropped in the rest of the manuscript. We find the continuity equation for the particle number
\[
\frac{d\rho_i^N}{dt} + \sum_{j \neq i} I_{ij}^N(t) = 0
\] (22)
where
\[
I_{ij}^N(t) = 2\Re[H_{ji}(t)G_{ij}^c(t,t)]
\] (23)
is the local particle current between sites $i$ and $j$, that satisfies $I_{ii}^N = -I_{ij}^N$. Using Eqs. (19), (20) and (21), it is easy to check that $\rho_i^N$ and $I_{ij}^N$ are gauge independent quantities.

2. Energy density, local energy current, and power density

In the static case, the energy operator coincides with the Hamiltonian operator. Actually, as pointed out in Ref. [22], this is only true if the scalar and vector potentials used to describe the static electromagnetic field are taken time independent but it is customary and natural to choose such a gauge for static fields.

In the time-dependent case, we follow Refs. [22,23] and define the energy operator $\hat{\varepsilon}$ as
\[
\hat{\varepsilon}(t) = \hat{H}(t) - e\hat{V}(t)
\] (24)
where $\hat{V}(t) = \sum_i V_i(t)\hat{c}_i$. The sum is made here over all sites $i$ in the whole system, including the leads $\mathcal{L}_\alpha$ where $V_i = V_\alpha$. By construction, $\langle \hat{\varepsilon} \rangle$ is gauge invariant. Indeed
\[
\langle \Psi|\hat{H} - e\hat{V}|\Psi\rangle = \langle \hat{\Omega}|\hat{H} - e\hat{V}|\hat{\Omega}|\Psi\rangle
\] (25)
in virtue of Eqs. (11), (12), and (15).

With this definition, the energy operator reads $\hat{\varepsilon}(t) = \sum_{i,j} \varepsilon_{ij}(t)\hat{c}_i(t)\hat{c}_j(t)$ with
\[
\varepsilon_{ii}(t) = H_{ii}^0
\] (26a)
\[
\varepsilon_{ij}(t) = H_{ij}(t) \quad \text{if } i \neq j
\] (26b)
and the gauge transformed energy operator reads $\tilde{\varepsilon}(t) = \sum_{i,j} \tilde{\varepsilon}_{ij}(t)\hat{c}_i(t)\hat{c}_j(t)$ with
\[
\tilde{\varepsilon}_{ii}(t) = H_{ii}^0
\] (27a)
\[
\tilde{\varepsilon}_{ij}(t) = H_{ij}(t)e^{\frac{i}{\hbar}[(\Lambda_i(t)) - \Lambda_j(t)]} \quad \text{if } i \neq j
\] (27b)
We now write the energy operator $\hat{\varepsilon}$ as a sum of local energy density operators $\hat{\varepsilon}_i$

$$\hat{\varepsilon} = \sum_i \hat{\varepsilon}_i$$ (28)

with

$$\hat{\varepsilon}_i(t) = \varepsilon_{ii}(t)\hat{c}_i^\dagger \hat{c}_i + \frac{1}{2} \sum_{j \neq i} \left( \varepsilon_{ij}(t)\hat{c}_i^\dagger \hat{c}_j + \varepsilon_{ji}(t)\hat{c}_j^\dagger \hat{c}_i \right)$$ (29)

containing both the on-site potential energy $\varepsilon_{ii}$ on site $i$ and half of the kinetic energy $\varepsilon_{ij}$ stored in the hoppings. Note that the definition of the energy density operator is not unique: There exist other $\hat{\varepsilon}_i$ that yield Eq. (28) and there is a priori no physical but only technical grounds to favor one choice over the others, as noticed in Ref. [83]. Our definition (29) corresponds to the discretized version on a lattice of the energy density of the second kind put forward in Ref. [83] which leads to a symmetrized energy current density ($I^E_{ij}$ below). The same definition has been used in e.g. Ref. [38,63,64].

To be fully precise, Ref. [38,63,64] dealt with the inherent ambiguity in the definition of the Hamiltonian density operator $H_i$ (so as $H = \sum_i H_i$) but the same discussion holds for $\hat{\varepsilon}_i$.

Let us now introduce $\rho^E_i = \langle \hat{\varepsilon}_i \rangle$ the (gauge invariant) energy density on site $i$ and let us write down the continuity equation for the energy with the help of Eqs. (19), (21), and (29). We find

$$\frac{d\rho^E_i}{dt} + \sum_{j \neq i} I^E_{ij}(t) = S^E_i(t)$$ (30)

where the local energy current $I^E_{ij}$ between sites $i$ and $j$ is given by

$$I^E_{ij}(t) = \sum_k \text{Re} \left[ \varepsilon_{kj}(t)\varepsilon_{ji}(t)G^E_{ik}(t,t) - \varepsilon_{ki}(t)\varepsilon_{ij}(t)G^E_{jk}(t,t) \right]$$ (31)

and the power source term $S^E_i$ on site $i$ by

$$S^E_i(t) = \sum_{j \neq i} \left\{ \hbar \text{Im} \left[ \frac{\partial \varepsilon_{ij}}{\partial t} G^E_{ji}(t,t) \right] + \text{Re} \left[ eV_i(t)\varepsilon_{ij}(t)G^E_{ji}(t,t) + eV_j(t)\varepsilon_{ji}(t)G^E_{ij}(t,t) \right] \right\} .$$ (32)

Using Eqs. (23) and (26), the source term can be written as

$$S^E_i(t) = \sum_{j \neq i} \left[ \frac{1}{2} (V_i(t) - V_j(t)) + \frac{\hbar}{2e} \frac{\partial \delta_{ij}}{\partial t} \right] eI^N_{ji}(t)$$ (33)

given by Eq. (2a). Eqs. (30) to (33) are derived in Appendix A. It is worth noting that the splitting into local energy current $I^E_{ij}(t)$ and source term $S^E_i(t)$ from the time derivative of the energy density in the continuity equation (30) is not unique. However the choice made above has several advantages:

1. * $I^E_{ij}$ and $S_i$ are gauge invariant quantities.
2. The energy change over the full system is given by only the external power source and not the energy currents, i.e.

$$\sum_i \frac{d\rho^E_i}{dt} = \sum_i S^E_i(t) .$$ (34)

3. The source term $S_i$ coincides with the electric power density supplied by the external time-dependent electromagnetic field.

4. $I^E_{ij} = -I^E_{ji}$ to fit the interpretation of a net current flowing from $i$ to $j$. Moreover $I^E_{ij} = 0$ if the sites $i$ and $j \neq i$ are disconnected (i.e. if $H_{ij} = 0$). The identification of a local energy current $I^E_{ij}$ out of the divergence $\sum_{j \neq i} I^E_{ij}$ is however not unequivocal. Another choice $I^E_{ij} \neq I^E_{ji}$ was made in Ref. [83]. It satisfies $\sum_j I^E_{ij} = \sum_j I^E_{ji}$ and $I^E_{ji} = -I^E_{ij}$ but contrary to $I^E_{ij}$, $I^E_{ji}$ can be non-zero between two disconnected sites.

5. In the static case $t \leq t_0$, the local energy current integrated over a lead $\mathcal{L}_\alpha$ (i.e. the energy current flowing in a lead $\mathcal{L}_\alpha$) coincides with the usual static definition of the energy current. This will be discussed in Section C.

C. Global currents

Hereafter, we integrate over space the local quantities introduced above and define in particular the particle, energy, and heat currents flowing in the leads. In the limit where the external electromagnetic field becomes time-independent, we compare those currents to the static ones given by the usual Landauer-Büttiker formula. As the latter formula are derived by taking the Hamiltonian as the energy operator, the two energy currents are different in general. However the two heat currents coincide in the static limit, as well as the two particle currents.

1. Particle currents

We define

$$N_S(t) = \sum_{i \in S} \rho^N_i(t)$$ (35a)

$$N_\alpha(t) = \sum_{i \in \mathcal{L}_\alpha} \rho^N_i(t)$$ (35b)
the particle number at time \( t \) in the scattering region \( S \) and in each lead \( \mathcal{L}_\alpha \). The continuity equation \cite{22} integrated over space yields

\[
I^S_S(t) = -\frac{dN_S}{dt} \tag{36a}
\]

\[
I^N_\alpha(t) = -\frac{dN_\alpha}{dt} \tag{36b}
\]

where

\[
I^N_\alpha(t) = \sum_{i \in \mathcal{L}_\alpha} \sum_{j \in S} I^N_{ji}(t) \tag{37}
\]

is the (incoming) particle current in the lead \( \mathcal{L}_\alpha \) (i.e. flowing towards the scattering region) and

\[
I^S_S(t) = \sum_{i \in S} \sum_{j \in \mathcal{L}_\alpha} I^S_{ji}(t) \tag{38}
\]

the displacement current. The total particle number is conserved and we have

\[
I^S_S(t) + \sum_\alpha I^N_\alpha(t) = 0. \tag{39}
\]

2. Energy currents

We proceed similarly for the energy-related quantities and define

\[
E_S(t) = \sum_{i \in S} \rho^E(t) \tag{40a}
\]

\[
E_\alpha(t) = \sum_{i \in \mathcal{L}_\alpha} \rho^E_i(t) \tag{40b}
\]

the energy at time \( t \) in the scattering region \( S \) and in each lead \( \mathcal{L}_\alpha \). By integrating spatially the continuity equation \cite{30}, we get

\[
\frac{dE_S}{dt} + I^E_S(t) = S^E_S(t) \tag{41a}
\]

\[
\frac{dE_\alpha}{dt} + I^E_\alpha(t) = S^E_\alpha(t) \tag{41b}
\]

where

\[
I^E_S(t) = \sum_{i \in S} \sum_{j \in \mathcal{L}_\alpha} I^E_{ji}(t) \tag{42a}
\]

\[
I^E_\alpha(t) = \sum_{i \in \mathcal{L}_\alpha} \sum_{j \in S} I^E_{ji}(t) \tag{42b}
\]

are respectively the energy current in the scattering region and the (incoming) energy current in the lead \( \mathcal{L}_\alpha \), while

\[
S^E_S(t) = \sum_{i \in S} S^E_i(t) \tag{43a}
\]

\[
S^E_\alpha(t) = \sum_{i \in \mathcal{L}_\alpha} S^E_i(t) \tag{43b}
\]

are the external power source terms. The energy currents in the leads and in the scattering region cancel each other, thus the conservation equation reads

\[
\frac{dE_S}{dt} + \sum_\alpha \frac{dE_\alpha}{dt} = S^E_S(t) + \sum_\alpha S^E_\alpha(t) \tag{44}
\]

i.e. the variation of the energy stored in the whole system equals the power supplied by the external electromagnetic field. Note that if for instance \( V_\alpha(t) = V_\alpha(t) \) are applied in the leads \( \mathcal{L}_\alpha \) but not in the scattering region \( (V_i(t) = 0 \) if \( i \in S \)), and if no time-dependent magnetic field is applied, then the source terms reduce to

\[
S^E_\alpha(t) = \frac{\epsilon}{2} V_\alpha(t) I^N_\alpha(t) \tag{45a}
\]

\[
S^E_S(t) = \frac{\epsilon}{2} \sum_\alpha V_\alpha(t) I^N_\alpha(t) \tag{45b}
\]

and the total source term is \( S^E_S + \sum_\alpha S^E_\alpha = \epsilon \sum_\alpha V_\alpha I^N_\alpha \).

3. Heat currents

We define the (incoming) time-dependent heat current in the lead \( \mathcal{L}_\alpha \) as

\[
I^H_\alpha(t) = I^E_\alpha(t) - S^E_\alpha(t) - \mu_\alpha I^N_\alpha(t) \tag{46}
\]

where \( \mu_\alpha \) is the electrochemical potential of the reservoir attached to \( \mathcal{L}_\alpha \) defined for \( t \leq t_0 \) in Sec.\cite{31}. This definition leads to the following formulation of the first law of thermodynamics

\[
\frac{dE_S}{dt} = S^E_S(t) + \sum_\alpha S^E_\alpha(t) + \sum_\alpha \mu_\alpha I^N_\alpha(t) + \sum_\alpha I^H_\alpha(t) \tag{47}
\]

where the first three terms on the right hand side of Eq.\cite{17} correspond to the rate of work supplied to the scattering region \( S \) by its environment. \( I^H_\alpha(t) \) defined above is gauge invariant since \( I^E_\alpha(t), S^E_\alpha(t) \) and \( I^N_\alpha(t) \) are. In a gauge where the leads are time-independent, the following equality holds

\[
I^H_\alpha(t) = -\frac{d}{dt} \langle \tilde{H}_\alpha + \frac{\tilde{\epsilon}}{2} \tilde{H}_S \rangle - \mu_\alpha I^N_\alpha(t) \tag{48}
\]

where \( \tilde{H}_\alpha \) and \( \tilde{H}_S \) denote respectively the gauge transformed Hamiltonian of the lead \( \mathcal{L}_\alpha \) and the gauge transformed tunneling Hamiltonian between \( \mathcal{L}_\alpha \) and the scattering region \( S \). Note that \( \tilde{H}_S \) may depend on time but not \( \tilde{H}_\alpha \) by construction. The term on the right-hand side of Eq.\cite{18} was used to define the lead heat current in Refs\cite{32,33,34,35}, in the case where the time-dependent perturbations are confined to the scattering region. It was argued in Ref\cite{36} that an extra term has to be added in the heat current definition when the tunneling Hamiltonian is also time-dependent. However in our case, this extra term is zero\cite{37} because the time dependency in the
hopping terms of our model Hamiltonian only appears through a time-dependent phase, \( \hat{H}_{ij}(t) = H_{ij}^{0}e^{i\phi_{ij}(t)} \) (whose origin is a time-dependent magnetic field or gauge transformation). Therefore, Eq. (46) is a gauge invariant formulation of the lead heat current which coincides with the definition used in Refs. 85,86 when a gauge in which the leads are time-independent is chosen. This point will be discussed in more details in Appendix [13]. Besides, we will see in the next subsection that \( I_{\alpha}^{H}(t) \) also coincides with the heat current given by the Landauer-Büttiker formula in the particular limit where \( \hat{H}(t) \) becomes time-independent. Finally, it is noteworthy that if we include the first cell of each lead into the scattering region, and define thereby new leads \( \mathcal{L}_{\alpha} \), then \( S_{\alpha}^{E}(t) = 0 \) and we have \( I_{\alpha}^{H}(t) = I_{\alpha}^{E}(t) - \mu_{\alpha}I_{\alpha}^{N}(t) \).

4. Static limit

When \( t \leq t_{0} \) and no external time-dependent electromagnetic field is applied, the system Hamiltonian is time independent i.e. \( \hat{H}(t \leq t_{0}) = \hat{H}^{0} \). Within the static Landauer-Büttiker formalism, the particle, energy, and heat currents in the lead \( \mathcal{L}_{\alpha} \) read\[85,86\]

\[ I_{\alpha}^{N, st}(t) = \sum_{\beta \neq \alpha} \frac{dE}{h} [f_{\mu_{\alpha},T_{\alpha}}(E) - f_{\mu_{\beta},T_{\beta}}(E)] T_{\alpha\beta}(E) \] (49a)

\[ I_{\alpha}^{E, st}(t) = \sum_{\beta \neq \alpha} \frac{dE}{h} [f_{\mu_{\alpha},T_{\alpha}}(E) - f_{\mu_{\beta},T_{\beta}}(E)] E T_{\alpha\beta}(E) \] (49b)

\[ I_{\alpha}^{H, st} = I_{\alpha}^{E, st} - \mu_{\alpha}I_{\alpha}^{N, st} \] (49c)

where \( f_{\mu,T}(E) = \left[ 1 + \exp \left( \frac{E - \mu}{k_{B}T} \right) \right]^{-1} \) is the Fermi function \( (k_{B} \) being the Boltzmann constant), the sum over \( \beta \) is a sum over leads \( \mathcal{L}_{\beta} \) and \( T_{\alpha\beta}(E) \) is the probability for an electron at energy \( E \) to be transmitted from the lead \( \mathcal{L}_{\beta} \) into the lead \( \mathcal{L}_{\alpha} \). It is straightforward to show that the particle \( I_{\alpha}^{N} \), energy \( I_{\alpha}^{E} \), and heat \( I_{\alpha}^{H} \) currents, defined above in Eqs. (49b), (49c), and (49c) respectively, equal the standard static current formula

\[ I_{\alpha}^{N}(t \leq t_{0}) = I_{\alpha}^{N, st} \] (50a)

\[ I_{\alpha}^{E}(t \leq t_{0}) = I_{\alpha}^{E, st} \] (50b)

\[ I_{\alpha}^{H}(t \leq t_{0}) = I_{\alpha}^{H, st} \] (50c)

This is true even in the time-dependent gauge (see the comment below Eq. (9)).

Let us now consider the case for \( t > t_{0} \) where an external time-dependent electromagnetic field is applied and let us assume that the field converges to a static limit at long times i.e \( \hat{H}(t \rightarrow \infty) = \hat{H}^{st} \). In this new static configuration, the static particle \( I_{\alpha}^{N, st} \), energy \( I_{\alpha}^{E, st} \), and heat currents \( I_{\alpha}^{H, st} \) are given by the Landauer-Büttiker formula [19] with \( \mu_{\alpha} \rightarrow \mu_{\alpha} + eV_{\alpha} \) and \( T_{\alpha\beta} \rightarrow T_{\alpha\beta} \). Here, \( V_{\alpha} \equiv V_{\alpha}(t \rightarrow \infty) \) in the leads \( \mathcal{L}_{\alpha} \) while \( T_{\alpha\beta} \) denote the transmissions of the system defined by \( \hat{H}^{st} \). In Appendix VII we show

\[ I_{\alpha}^{N}(t \rightarrow \infty) = I_{\alpha}^{N, st} \] (51a)

\[ I_{\alpha}^{E}(t \rightarrow \infty) = I_{\alpha}^{E, st} - eV_{\alpha}I_{\alpha}^{N, st} + S_{\alpha}^{E}(t \rightarrow \infty) \] (51b)

\[ I_{\alpha}^{H}(t \rightarrow \infty) = I_{\alpha}^{E, st} - (\mu_{\alpha} + eV_{\alpha})I_{\alpha}^{N, st} = I_{\alpha}^{H, st} \] (51c)

Thus in the static limit \( t \rightarrow \infty \), the energy currents \( I_{\alpha}^{E}(t \rightarrow \infty) \) in the leads \( \mathcal{L}_{\alpha} \) differ from the usual static energy currents \( I_{\alpha}^{E, st} \). This is due to the fact that we defined the energy operator as given by Eq. (24), and not as the Hamiltonian operator. However, the heat currents in the leads converge to the usual static heat currents in the static limit.

IV. NUMERICAL METHOD

We now discuss how to compute in an efficient way the time-dependent quantities introduced in Sec. [III]. We use for that purpose the wave-function based approach developed in Refs. 25,27 which has been shown to be formally equivalent to the NEGF formalism but much more efficient from a computational point of view. This approach is at the root of the numerical package t-Kwant [28] which extends to the time domain the quantum transport package Kwant 85,86. To date, t-Kwant has been used for calculating time resolved particle density and particle current in various systems.29,30,31,32,33,34,35,36,37,38 The case of particle current noise has also been dealt with in Ref. 41. Hereafter, we present succinctly the t-Kwant algorithm and explain how to use it for the calculation of the time resolved energy density, power density, energy current and heat current. Note that the same wave-function based approach has recently been used in Ref. 43 for calculating energy currents in molecular networks. We report here on its implementation in the t-Kwant package.

A. Choice of the electromagnetic gauge

All quantities introduced in Sec. [III] i.e. \( \rho_{i}^{N}, \rho_{i}^{E}, I_{ij}^{N}, I_{ij}^{E}, \) and \( S_{i}^{E} \) have been shown to be gauge invariant. We are therefore free to choose a convenient electromagnetic gauge for numerical calculation. For \( t \leq t_{0} \), the t-Kwant algorithm requires to work in the natural gauge in which the system Hamiltonian is time-independent (i.e. \( \Lambda_{i}(t \leq t_{0}) = 0 \) everywhere). Another prerequisite for t-Kwant is the absence of time dependency in the leads. This can be always achieved by fixing the gauge function \( \Lambda_{i}(t) \) in the leads to

\[ \Lambda_{i}(t) = \phi_{i}(t) \] if \( i \in \mathcal{L}_{\alpha} \] (52)

where \( \phi_{i}(t) = \int_{0}^{t} du V_{i}(u) \). Indeed, under the gauge transformation (7), the Hamiltonian defined in Eqs. (3)- (6) transforms as \( \hat{H}(t) \rightarrow \hat{H}(t) \) according to Eq. (9), and
one finds eventually time-independent leads in the new gauge

\[ \tilde{H}_{ij}(t) = H_{ij}^0 \quad \text{if } i \in \mathcal{L}_\alpha, j \in \mathcal{L}_\alpha \]  

while the system-lead coupling terms acquire an additional time-dependent phase

\[ \tilde{H}_{ij}(t) = H_{ij}(t)e^{i(\phi_{ij}(t) - \Lambda_j(t))} \quad \text{if } i \in \mathcal{L}_\alpha, j \in S. \]  

There is however no restriction on the gauge function \( \Lambda_j(t) \) in the scattering region \( S \) for \( t > t_0 \). It can be chosen arbitrarily.

B. Main steps of the t-Kwant algorithm

In this section, we do not present any original result but outline the main steps of the t-Kwant algorithm following Refs.\textsuperscript{[25,22]}. We use boldface letters to denote matrices, e.g. \( \tilde{H} \) is the matrix whose elements are \( \tilde{H}_{ij} \). Without loss of generality, we also fix \( t_0 = 0 \) in order to lighten the equations below.

The central objects of the t-Kwant numerical technique are the time-dependent scattering states \( \Psi^{m,\alpha,E}(t) \), solutions of the Schrödinger equation

\[ i\hbar \frac{\partial}{\partial t} \tilde{\Psi}^{m,\alpha,E}(t) = \tilde{H}(t)\Psi^{m,\alpha,E}(t) \]  

with the initial condition

\[ \tilde{\Psi}^{m,\alpha,E}(t = 0) = \Psi^{m,\alpha,E,0}. \]  

The tildes on top of \( \Psi^{m,\alpha,E} \) and \( \tilde{H} \) are written to remind us that the t-Kwant gauge \textsuperscript{[52]} is used. The stationary scattering states \( \Psi^{m,\alpha,E,0} \) labelled by their energy \( E \) and their incoming mode \( m, \alpha \) (in lead \( \mathcal{L}_\alpha \)) characterize the static problem for \( t \leq 0 \)

\[ H_{ij}^0 \Psi^{m,\alpha,E,0} = E \Psi^{m,\alpha,E,0}. \]  

They can be calculated with the Kwant library. Note that while \( E \) corresponds to the energy of the stationary wave-function \( \Psi^{m,\alpha,E,0} \), it cannot be interpreted as the energy of the time-evolved scattering state \( \tilde{\Psi}^{m,\alpha,E}(t) \) since energy is not conserved in a time-dependent setup. In practice, Eq.\textsuperscript{(53)} is numerically intractable as it is defined on the whole (infinite) lattice. To circumvent this problem, a change a variable \( \tilde{\Psi}^{m,\alpha,E}(t) = e^{iEt/h} \Psi^{m,\alpha,E}(t) - \Psi^{m,\alpha,E,0} \) is made. The new wave-functions \( \tilde{\Psi}^{m,\alpha,E}(t) \) satisfy the Schrödinger-like differential equation

\[ i\hbar \frac{\partial}{\partial t} \tilde{\Psi}^{m,\alpha,E}(t) = [\tilde{H}(t) - E] \tilde{\Psi}^{m,\alpha,E}(t) + S^{m,\alpha,E}(t) \]  

with the initial condition

\[ \tilde{\Psi}^{m,\alpha,E}(t = 0) = 0 \]  

and an additional source term

\[ S^{m,\alpha,E}(t) = [\tilde{H}(t) - H_{ij}^0] \Psi^{m,\alpha,E,0} \]  

which is non zero only in a finite central region since the leads are time independent in the t-Kwant gauge (see Sec.IV A). For this reason and as \( \tilde{\Psi} \) (adapted wave-function) changes everywhere and \( \tilde{\Psi}^{m,\alpha,E}(t) \) is composed of outgoing modes only, it is sufficient to solve Eqs.\textsuperscript{(58)-(60)} in a finite system around \( S \) i.e. it is possible to truncate the leads (after having calculated \( \tilde{\Psi}^{m,\alpha,E,0} \)). It is necessary however to get rid of spurious reflections of outgoing waves on the truncated lead boundaries. This can be done in different ways\textsuperscript{[25]}. The most efficient one consists in adding an imaginary onsite potential \( i\Sigma_x \) over the first lead unit cells (labelled \( x = 1, 2, \ldots \) from the scattering region) and to make it vary smoothly with \( x \) in order to absorb the outgoing waves and suppress reflections. Eventually, one solves

\[ i\hbar \frac{\partial}{\partial t} \tilde{\Psi}^{m,\alpha,E}(t) = [\tilde{H}(t) - E - i\Sigma] \tilde{\Psi}^{m,\alpha,E}(t) + S^{m,\alpha,E}(t) \]  

together with Eqs.\textsuperscript{(58)-(60)} in a finite region made of \( S \) and a finite portion of the leads. This is done with the Dormand-Prince (Runge-Kutta) method. The sink term which reads \( \Sigma = \Sigma_x \chi_{ij} \) in the first lead cells (and \( \Sigma = 0 \) elsewhere) can be designed in such a way that the reflection amplitude of outgoing waves is arbitrarily close to zero. Its expression is given in Ref.\textsuperscript{[25]}, together with more details about the source-sink algorithm outlined above.

Once the time-dependent wave-functions \( \tilde{\Psi}^{m,\alpha,E}(t) \) are computed, the particle density \( \rho^{N}(t) \) and the particle current \( I^{N}_{ij}(t) \) given by Eqs.\textsuperscript{(20) and (23)} respectively can be deduced using\textsuperscript{[25]}

\[ G^{\leq}_{ij}(t, t') = i \sum_{\alpha} \sum_{m} \int \frac{dE}{h} f_{\alpha}(E) \left[ \tilde{\Psi}^{m,\alpha,E}(t') \right]^* \tilde{\Psi}^{m,\alpha,E}(t) \]  

where \( f_{\alpha}(E) = f_{\mu,\gamma}(E) \) is a shorthand notation for the Fermi function and \( \tilde{\Psi}^{m,\alpha,E}(t) \) denotes the wave-function value at site \( i \). Eq.\textsuperscript{(62)} is the cornerstone of the present manuscript as it relates the NEGF approach (used in Sec.III) to the t-Kwant wave-function approach (used hereafter for numerical implementation). \( \rho^{N}_{ij}(t) = -i\hbar G^{\leq}_{ij}(t, t) \) is directly given by Eq.\textsuperscript{(62)} while \( I^{N}_{ij}(t) \) reads in terms of the scattering states

\[ I^{N}_{ij}(t) = -2 \sum_{\alpha} \sum_{m} \int \frac{dE}{h} f_{\alpha}(E) \times \text{Im} \left[ \left( \tilde{\Psi}^{m,\alpha,E}(t') \right)^* \tilde{H}_{ji}(t) \tilde{\Psi}^{m,\alpha,E}(t) \right]. \]  

Hence both quantities can be computed with t-Kwant by integrating over the scattering states which were initially occupied at \( t = 0 \). In practice, the integration is preferably done in momentum instead of energy (to avoid divergent behavior of the integrand in the vicinity of band
openings). We emphasize that Eq.\[63\] can also be written without the tildes since \(I^N_{\gamma}(t)\) is gauge invariant. The same goes for \(\rho^N_{\gamma}(t) = -i\hbar G^<_{\gamma}(t,t)\). However, technically, the calculations are done in the t-Kwant gauge. This is the reason why we kept the tildes in the formula.

C. Generalization to energy transport

The local energy density \(\rho^E = \langle \hat{\varepsilon}_i \rangle\) and the local energy currents \(I^E_{ij}(t)\) written as a function of the lesser Green’s function \(G^<_{ij}(t,t)\) in Eqs.\[29\] and \[43\] respectively can be readily expressed in the wave-function formalism with the help of Eq.\[62\]. One finds\[63\]

\[
\rho^E_{\gamma}(t) = \sum_{\alpha} \sum_{m_\alpha} \int \frac{dE}{2\pi} f_{\alpha}(E) \times \sum_j \Re \left[ \left( \tilde{\Psi}^{m_\alpha E} \right)^* \tilde{\varepsilon}_{ij}(t) \tilde{\Psi}^{m_\alpha E} \right] \tag{64}
\]

and

\[
I^E_{ij}(t) = \sum_{\alpha} \sum_{m_\alpha} \int \frac{dE}{\hbar} f_{\alpha}(E) \times \sum_k \Im \left[ \left( \tilde{\Psi}^{m_\alpha E} \right)^* \tilde{\varepsilon}_{kj}(t) \tilde{\varepsilon}_{ji}(t) \tilde{\Psi}^{m_\alpha E} \right] - \left( \tilde{\Psi}^{m_\alpha E} \right)^* \tilde{\varepsilon}_{kj}(t) \tilde{\varepsilon}_{ji}(t) \tilde{\Psi}^{m_\alpha E} \tag{65}
\]

Both quantities can be computed with t-Kwant, in the same spirit as \(\rho^N_{\gamma}(t)\) and \(I^N_{ij}(t)\) but with an additional sum over the system sites. The electric power density \(S^E(t)\) given by Eq.\[43\] can be computed as well. As before, all tildes can be dropped in Eqs.\[64\] and \[65\] but in practice, the calculation is done in the t-Kwant gauge \(i.e\), with the tilded quantities. Those local quantities can eventually be summed up over space to deduce the lead energy currents \(I^E_{\alpha}(t)\) and the lead heat currents \(I^H_{\alpha}(t)\). We have implemented new (Cython) classes in t-Kwant under the energy module to compute these quantities (see Appendix E for more details). In the following, we perform t-Kwant simulations of (electronic) heat transport in the paradigmatic time-dependent RLM, in order to validate our approach and our numerical implementation. We also report on an exploratory investigation of time-dependent heat transport in a QPC driven by voltage pulses. Without discussing deeply the physics involved, we illustrate the strong potential of the t-Kwant (extended) platform for the study of dynamical thermoelectrics and caloritronics.

V. RESONANT LEVEL MODEL AS A BENCHMARK

The (non-interacting) time-dependent RLM has been extensively studied in the literature to simulate dynamical charge transport (see e.g. Refs.\[28, 105\] and more recently dynamical energy transport\[96, 106, 107\] in a single level quantum dot or molecular junction connected to two electronic reservoirs. Hereafter we use this model as a testbed to benchmark our numerical approach described above. We consider two cases: (i) when (only) the dot level \(\epsilon_0(t)\) is varied in time as \(\epsilon_0(t) = \epsilon_0 + eV_0 \Theta(t)\), and (ii) when the time-dependent step-like perturbation is performed in the leads. We calculate the time-dependent energy and heat currents with our numerical approach and show that we reproduce in the expected limits the results obtained previously in the literature.

A. Model

We consider a one-dimensional chain made of a central site 0 with on-site energy \(\epsilon_0(0)\) connected through a nearest-neighbor hopping term \(\gamma_c\) to two semi-infinite left \((L, \text{on sites} i \leq -1)\) and right \((R, \text{on sites} i \geq 1)\) leads with on-site energies \(\epsilon_L(t)\) and \(\epsilon_R(t)\), and a nearest-neighbor hopping term \(\gamma\). The Hamiltonian reads

\[
\hat{H}(t) = \hat{H}_0(t) + \sum_{\alpha=L,R} \hat{H}_\alpha(t) + \sum_{\alpha=L,R} \hat{H}_{\alpha\alpha} \tag{66}
\]

where

\[
\hat{H}_0(t) = \epsilon_0(t) \hat{c}_0^\dagger \hat{c}_0 \tag{67}
\]

is the dot Hamiltonian,

\[
\hat{H}_\alpha(t) = \sum_{i \geq 1} \left[ \epsilon_\alpha(t) \hat{c}_i^\dagger \hat{c}_i + \gamma \hat{c}_i^\dagger \hat{c}_{i+1} + \gamma \hat{c}_{i-1}^\dagger \hat{c}_i \right] \tag{68}
\]

the Hamiltonian of the lead \(\alpha = L \text{ or } R\), and

\[
\hat{H}_{\alpha\alpha} = \gamma_c \epsilon_0^2 + h.c. \tag{69}
\]

the tunneling Hamiltonian between the dot and the lead \(\alpha\). In Eqs.\[68\] and \[69\], \(a - [+]|\) sign has to be taken if \(\alpha = L [R]\). The parameters \(\epsilon_0(t)\) and \(\epsilon_\alpha(t)\) are constant in time for \(t \leq t_0(=0)\). Note that within the t-Kwant approach, the time-dependence of the lead on-site energies \(\epsilon_\alpha(t) = \epsilon_\alpha + eV_\alpha(t) \Theta(t)\) is gauged out \((\epsilon_\alpha(t) \rightarrow \epsilon_\alpha)\) while the dot-leading hopping term \(\gamma_c\) acquires a dynamical phase \((\gamma_c \rightarrow \gamma_c e^{-i \gamma_c \int_0^t d\tau e^{i\omega_0 \tau}}\), see Sec.\[IV A\]. Finally, each lead \(\alpha\) is attached from the remote past to an electronic reservoir at equilibrium with static electrochemical potential \(\mu_\alpha\) and temperature \(T_\alpha\) defined for \(t \leq 0\). They remain at equilibrium for \(t > 0\). Only the electric part of the electrochemical potential may become time-dependent (depending on the gauge). The chemical potential and the temperature are supposed to remain constant.

B. Results for a time-dependent dot energy level

Let us first consider the case where \(\epsilon_L(t) = \epsilon_R(t) = 0\) while a step-like variation \(\epsilon_0(t) = \epsilon_0 + eV_0 \Theta(t)\) of the
This configuration has the advantage of being analytically tractable with the NEGF technique in the so-called wide-band limit approximation. Moreover, since the time-dependent perturbations are restricted to the dot level $\epsilon_0(t)$, the energy operator $\hat{e}$ coincides in this case with the Hamiltonian operator in the leads, and we have $E_\alpha = (H_\alpha + \frac{1}{2} \hat{H}_{0\alpha})$ where $E_\alpha$ is defined by Eq. (40b). Hereafter, we calculate with t-Kwant the time-dependent heat current $I^H(t) = -\frac{dE_\alpha}{dt} - \mu_L I_L^N(t)$ in e.g. the left lead (see Eqs. (16) and (41b)) and compare it to the one obtained within the NEGF formalism under the wide-band limit approximation (see Appendix D). A similar comparison is done for the particle current $I_L^N(t)$ and for an alternative heat current $\tilde{I}_L^H(t) = -\frac{d\langle H_L \rangle}{dt} - \mu_L I_L^N(t)$ which does not include the contribution of the lead-dot tunneling Hamiltonian $\hat{H}_{0L}$. Such a definition of the heat current was considered in e.g. Ref. 42. Note that in the wave-function formalism, we have for the present model

$$\frac{d\langle \hat{H}_L \rangle}{dt} = 2 \sum_\alpha \sum_{m_\alpha} \int \frac{dE}{\hbar} f_\alpha(E) \times \gamma \gamma_c \text{Im} \left[ \langle \Psi_{m_\alpha E} \rangle \Psi_{m_\alpha E}^* \right]. \quad (70)$$

This allows us to compute $\tilde{I}_L^H(t)$ with t-Kwant. $I_L^N(t) = I_{0-1}^N(t)$ and $I_L^H(t) = I_{0-1}^E(t) - S_{E_0} E_0(t) - \mu_L I_L^N(t)$ are calculated using Eqs. (59), (63), and (65).

To make the comparison between the t-Kwant and the NEGF results in the wide-band limit, we follow the scaling approach used in Ref. 42. We vary simultaneously the hopping terms in the chain by replacing $\gamma$ and $\gamma_c$ parameters with

$$\tilde{\gamma} = \lambda \gamma \quad \text{(71a)}$$

$$\tilde{\gamma}_c = \sqrt{\lambda} \gamma_c \quad \text{(71b)}$$

where $\lambda$ is a scaling factor. When $\lambda$ is increased, the bandwidth $[-\tilde{\gamma}, 2\tilde{\gamma}]$ of the leads widens while the ratio $\Gamma = 4\tilde{\gamma}^2/\tilde{\gamma}$ remains fixed. In the limit $\lambda \gamma_0/\Gamma \to \infty$ (keeping $\Gamma$ finite), the retarded self-energy $\Sigma^R(E)$ of the (idemntical) time-independent left and right leads,

$$\Sigma^R(E) = \frac{\tilde{\gamma}^2}{\tilde{\gamma}} \left[ \frac{E}{2\tilde{\gamma}} - i \sqrt{1 - \left( \frac{E}{2\tilde{\gamma}} \right)^2} \right] \quad \text{if} \quad |E|/|\tilde{\gamma}| \leq 1, \quad (72)$$

converges to $-i\tilde{\gamma}/\tilde{\gamma}$ i.e. the real part of $\Sigma^R(E)$ becomes zero and its imaginary part becomes energy independent. This corresponds to the wide-band limit hypothesis.

In Fig. 1, we plot $I_L^N(t)$, $I_L^H(t)$, and $\tilde{I}_L^H(t)$ calculated with t-Kwant for various values of the ratio $\lambda \gamma_0/\Gamma = \lambda \gamma_0 / \gamma_c^2/4$, keeping the other parameters fixed. We check that in the wide-band limit $\lambda \gamma_0/\Gamma \gg 1$, the t-Kwant results (black lines in Fig. 1) converge to the NEGF results given in Appendix D. Moreover, in the inset of Fig. 1(c), we compare $I_L^H(t)$ and $\tilde{I}_L^H(t)$ and show that both quantities coincide in the long...
time limit $\Gamma t/\hbar \to \infty$. This is illustrated in the wide-band limit $\lambda \gamma/\Gamma \to \infty$ but holds for any value of $\lambda \gamma/\Gamma$ (though the smaller $\lambda \gamma/\Gamma$, the slower the convergence). Such an equality between $I^H (t)$ and $\tilde{I}^H (t)$ at long times is expected as the energy may be stored only temporarily in the lead-dot coupling region. Finally, we also check that in the long time limit $\Gamma t/\hbar \to \infty$, the $t$-Kwant particle and heat currents converge to the static particle and heat currents $I^H_{N/H,s_2}$ given by the Landauer-Büttiker formula (horizontal dashed lines in Fig.1), as expected from Eqs.\((51a)\) and \((51c)\).

C. Results for a time-dependent voltage bias

We continue studying the RLM but now consider that a voltage bias is suddenly applied in the left lead, i.e. $\epsilon_L(t) = eV_L \Theta(t)$, while $\epsilon_R(t) = \epsilon_0$ and $\epsilon_R(t) = 0$ (see Insert of Fig.2). This model under the same configuration has been studied in Ref.\(^{22}\) with an exact (partition-free) numerical approach\(^{22}\) which is formally equivalent to the $t$-Kwant approach. The authors calculated the time-dependent particle currents $I^N_{\alpha}(t)$ in the leads $\alpha = L$ and $R$, as well as some time-dependent heat current\(^{22}\)

\[
Q_{\alpha}(t) = -\frac{d}{dt} \langle H_{\alpha} \rangle - \mu_{\alpha} I^N_{\alpha}(t).
\]

In the present case, $Q_{\alpha}(t)$ and the gauge invariant heat currents $I^H_{\alpha}(t)$ are linked by the relations (see Appendix \(B\))

\[
\begin{align}
I^H_{L}(t) &= Q_L(t) - eV_L I^N_L(t) + eV_L N_L \delta(t) \tag{73a} \\
I^H_{R}(t) &= Q_R(t) \tag{73b}
\end{align}
\]

where $N_L$ is the particle number in the left lead defined in Eq.\((45b)\). Note that $Q_L(t)$ contains the term $-\partial (\langle H_L \rangle)/\partial t$ (see Eq.\((21)\)), which cancels out the $\delta(t)$ term in Eq.\((73a)\). Using $I_0(t)$ and $Q_0(t)$ data\(^{20}\) issued from Ref.\(^{22}\), we build up $I^H_{\alpha}(t)$ data for $t > 0$ according to Eq.\((73)\) and compare them to the ones calculated with $t$-Kwant. We find a perfect agreement (see Fig.2). This provides a supplementary validity check of our approach and highlights the difference between the gauge invariant heat current $I^H_{\alpha}(t)$ and the gauge dependent heat current $Q_{\alpha}(t)$ when a time-dependent voltage is applied in the lead $\alpha$.

VI. QUANTUM POINT CONTACT

To illustrate the potential of our $t$-Kwant based numerical approach, we simulate hereafter dynamical (electronic) heat transport in a QPC attached to two reservoirs held at different temperatures. We focus on the possibility of extracting heat from the cold reservoir by Peltier effect and ask whether or not Peltier cooling may be enhanced by applying time-resolved voltage pulses to one of the two electrodes attached to the QPC (instead of a constant voltage bias across the system).

We consider a nanoribbon of length $L$ and width $W$ connected through semi-infinite leads to two left ($L$) and right ($R$) electronic reservoirs maintained at temperatures $T_L \lesssim T_R$ and electrochemical potentials $\mu_L \geq \mu_R$ (see Fig.3(a)). The system is discretized on a square lattice (with lattice spacing $a = 1$). For times $t \leq 0$, no time-dependent perturbation is applied and the system Hamiltonian $\hat{H}(t \leq 0) = \hat{H}^0$ reads

\[
\hat{H}^0 = \sum_i \left( 4\gamma + U_i \right) \hat{c}_i^\dagger \hat{c}_i - \gamma \sum_{(i,j)} \hat{c}_{i}^\dagger \hat{c}_j
\]

where $\gamma$ is the nearest-neighbor hopping term and $U_i$ is the QPC confining potential modeled by

\[
U_i = \begin{cases} 
\left( \frac{\mu}{\tau_p} \right)^2 \left[ 1 - 3 \left( \frac{2\mu}{\tau_p} \right)^2 + 2 \left( \frac{2\mu}{\tau_p} \right)^3 \right] & \text{if } |x_i| < \frac{l_x}{2} \\
0 & \text{if } |x_i| \geq \frac{l_x}{2}.
\end{cases}
\]

Here $l_x$ and $l_y$ are two parameters controlling the QPC shape and the site of coordinates $(x_i, y_i) = (0, 0)$ is taken at the center of the ribbon. The staircase-like transmission function $T(E)$ of the QPC in the static configuration (computed with Kwant) is plotted in Fig.3(b) for a given set of parameters used hereafter. We also fix $T_L \approx T_R$ and choose $\mu_R$, so as $T(E = \mu_R) \approx 0.6$ (guided by the fact that thermoelectric effects are to be sought near transmission steps in the adiabatic regime). The value of $\mu_L \geq \mu_R$ is determined by the condition $I^H_{L}(t \leq 0) = 0$.

From time $t = 0$, we apply in the left lead a gaussian voltage pulse $V_L(t) = V_L \exp\left[-4 \ln(2) \frac{(t - \tau_p)^2}{\tau_p^2}\right]$ of width $\tau_p$, amplitude $V_p$ and center $3\tau_p$. Therefore, the system Hamiltonian becomes $\hat{H}(t > 0) = \hat{H}^0 + \sum_{i \in L} V_L(t) \hat{c}_i^\dagger \hat{c}_i$.

Using $t$-Kwant and the embedded energy module, we...
compute the time-resolved particle ($I_L^N$) and heat ($I_L^H$) currents in the left lead. Data are shown in panels (d) to (f) of Fig.3 for different pulse parameters ($\tau_p, V_p$) with fixed $n_p = (e/h) \int V_L(t) dt = (eV_p\tau_p)/(4\hbar\sqrt{\pi \ln 2})$ (total number of electrons injected by the voltage pulse in the left lead). To avoid spurious effects that appear when the edges of the system’s conduction band are probed, we consider relatively long pulses with $h/\tau_p, V_p \lesssim \mu_L, \mu_R$ (but short enough to investigate the non-adiabatic regime). The t-Kwant currents are compared to the adiabatic currents $I_{L,\text{N}}^{\text{st}}(V_L(t))$ and $I_{L,\text{H}}^{\text{st}}(V_L(t))$ given by the Landauer-Büttiker formula (see Section IIIC4). The latter depend parametrically on time through $V_L(t)$. They are computed for static systems by using Kwant and a numerical integrator over the energy. For small $\tau_p$ (short pulses, see panel (d)), the particle current $I_L^N(t)$ shows a first positive peak centered around $3\tau_p$ corresponding to the injected pulse and some time later, a second negative peak corresponding to the reflected part of the pulse. Both peaks are well resolved in this (non-adiabatic) regime. They contribute to two main negative peaks in the heat current $I_L^H(t)$. For large $\tau_p$ (long pulses, see panel (g)), the t-Kwant currents converge to the adiabatic currents characterized by a single peak centered at $3\tau_p$. We note that the particle current converges more slowly to its adiabatic limit than the heat current. The crossover between the two regimes is shown in panels (e) and (f). Obviously, the time-resolved t-Kwant currents in the non-adiabatic regime depend on the position of the interface in the left lead at which they are calculated (green dashed line in Fig.3(a)). However, the currents integrated over time are independent of this position. In panel (c) of Fig.3 we plot $\int dt [I_L^N(t) - I_L^N(t = 0)]$ as a function of $\tau_p$ ($I_L^H(t = 0) = 0$ by construction). We find that heat can be extracted from the cold reservoir ($\int dt I_L^H(t) > 0$) in the limit of long pulses only and for all $\tau_p$, we have $\int dt I_L^H(t) \leq \int dt I_L^{H,\text{st}}(V_L(t))$. Thus, the application of short voltage pulses involving a non-adiabatic response of the quantum system turns out to be detrimental to Peltier cooling (at least for the set of parameters considered here). A detailed study of Peltier and Seebeck thermoelectric effects in a time-dependent QPC is left for future works. The present preliminary investigation shows the feasibility of further studies. Indeed, the set of t-Kwant curves shown in panels (d) to (g) of Fig.3 required a few hours (d) to a few days (g) of computation time on a single CPU core.

**VII. CONCLUSION**

We have built up a gauge invariant theoretical framework for studying time-dependent thermoelectric transport through a broad class of electronic quantum systems, in the absence of electron-electron and electron-phonon interactions. To simulate this approach on
large scale, we have adopted the wave-function formulation of time-dependent quantum transport drawn up in Refs. [25–27], which is formally equivalent to the NEGF formalism, the Floquet theory (for periodic perturbations), and the partition-free approach. We have thereby implemented a complementary energy module to the t-Kwant library, the latter being until then employed for time-dependent particle transport. We have checked that the built-in platform reproduces the expected results for the time-resolved heat currents in the Resonant Level Model and have performed preliminary investigations of dynamical heat transport in a larger system made up of about one thousand sites. The approach benefits from t-Kwant advantages in terms of versatility, user-friendliness, and computational efficiency. It provides a numerical testbed for the study of time-dependent thermoelectrics and caloritronics in realistic electronic quantum systems, beyond the adiabatic limit.

For the sake of simplicity, we have ignored the spin degree of freedom and considered a spinless model throughout the paper. Yet, there is no technical limitation at Kwant’s or t-Kwant’s level as both softwares have been devised in such a way that it is easy from a user or a developer point of view to account for spin, orbital, or electron-hole degrees of freedom. The difficulty arises from the choice of the energy operator $\hat{\varepsilon}$ and from the interpretation of the different terms in the energy continuity equation. While for instance the inclusion of the Zeeman term is straightforward, the one of spin-orbit coupling is less obvious.

Another natural extension of this work shall be the inclusion of the Coulomb interaction at the mean field level. Indeed it was argued by Büttiker et al. [101,102] that a proper treatment of electrostatics is needed to restore (i) particle current conservation i.e. $\sum_j I_j^N(t) = 0$ and (ii) the condition of (strong) gauge invariance i.e. the absence of particle current generation upon varying the potential in all the leads simultaneously. This is also true for electronic heat current though (i) may not be verified due to dissipation. Importantly, condition (ii) is a stronger form of gauge invariance than the one considered in the present paper and it is not satisfied within our non-interacting theory. To go further, one could follow the approach used in Ref. [91] and solve the time-dependent Hartree problem with t-Kwant in order to describe eventually time-dependent heat and thermoelectric transport together with electrostatic effects.

We thank Fabienne Michelini for interesting discussions about the energy current definition as well as Florian Eich and his co-authors for sharing the data of Ref. [69] used in Fig. 2.

Appendix A: Derivation of the energy continuity equation [40]

Using the equation of motion [21] for $\dot{\varepsilon}_i$ and the definition [24] of the energy operator, we find

$$\frac{d\hat{\varepsilon}_i}{dt} - \frac{i}{\hbar} \langle [\hat{\varepsilon}(t), \hat{\varepsilon}_i(t)] \rangle = \frac{i}{\hbar} \langle [e\hat{V}(t), \hat{\varepsilon}_i(t)] \rangle + \langle \frac{\partial \hat{\varepsilon}_i}{\partial t} \rangle. \quad (A1)$$

We identify the right-hand side of the above equation with the source term $S_i^E$ and $\langle [\hat{\varepsilon}, \hat{\varepsilon}_i] \rangle$ with $I_j^E$. With this choice, the equality $\sum_{j} I_j^E = 0$ is straightforward. After a few lines of calculation, we get

$$\frac{i}{\hbar} \langle [\hat{\varepsilon}, \hat{\varepsilon}_i] \rangle = \sum_{k,j} \text{Re} \left[ \varepsilon_{ki} \varepsilon_{ij} G_{jk}^< + \varepsilon_{kj} \varepsilon_{ji} G_{ik}^< \right] \quad \text{(A2)}$$

$$\frac{i}{\hbar} \langle [e\hat{V}, \hat{\varepsilon}_i] \rangle = \sum_{j} \text{Re} \left[ eV_i \varepsilon_{ij} G_{ji}^< + eV_j \varepsilon_{ji} G_{ij}^< \right] \quad \text{(A3)}$$

$$\langle \frac{\partial \hat{\varepsilon}_i}{\partial t} \rangle = \sum_{j} \hbar \text{Im} \left[ \frac{\varepsilon_{ij}}{\partial t} G_{ji}^< \right]. \quad \text{(A4)}$$

Here the explicit time dependency of the different terms have been omitted for compactness. Eqs. (A3) and (A4) lead to Eq. (32) after noticing that the terms for $j = i$ are zero. Eq. (A2) does not allow us to identify immediately the local energy current $I_j^E$ as we seek an expression of $I_j^E$ that satisfy $I_j^E = -I_{ji}^E$. To go further, we use the fact that $\sum_{k,j} \text{Re} [\varepsilon_{ki} \varepsilon_{ij} G_{jk}^<] = 0$ since $\varepsilon^*_{ij} = \varepsilon_{ji}$ and $[G_{jk}^<]^* = -G_{kj}^<$, and we rewrite Eq. (A2) as

$$\frac{i}{\hbar} \langle [\hat{\varepsilon}, \hat{\varepsilon}_i] \rangle = \sum_{k,j} \text{Re} \left[ \varepsilon_{kj} \varepsilon_{ji} G_{ik}^< - \varepsilon_{ki} \varepsilon_{ij} G_{jk}^< \right] \quad \text{(A5)}$$

to be identified with $-\sum_j I_j^E = -\sum_j I_{ji}^E$. This provides Eq. (31) and completes the proof of Eq. (30). As pointed out in Sec. III B 2, this choice for $I_j^E$ is not unique.

Appendix B: Discussion of the lead heat current definition [46]

The purpose of this Appendix is to compare the lead heat current $I_j^H(t)$ defined by Eq. (46) with the lead heat current $Q_{\alpha}(t)$ used in Refs. [82,90,99] and defined by

$$Q_{\alpha}(t) = -\frac{d}{dt} \langle \hat{H}_{\alpha} + \frac{1}{2} \hat{H}_{S\alpha} \rangle - \mu_{\alpha} I_j^N(t) \quad \text{(B1)}$$

where $\hat{H}_{\alpha}$ is the Hamiltonian of the lead $L_{\alpha}$ and $\hat{H}_{S\alpha}$ the tunneling Hamiltonian between $L_{\alpha}$ and the scattering

ACKNOWLEDGMENTS

We acknowledge the financial support of the CrossDisciplinary Program on Numerical Simulation of CEA, the French Alternative Energies and Atomic Energy Commission. We are grateful to Christoph Groth, Thomas Kloss, Benoît Rossignol, Xavier Waintal, and Josef Weston for introducing us to t-Kwant and for their help in the implementation of the energy-related routines.
which yields $\sum_{i \in L_\alpha} \dot{H}_i = \dot{H}_\alpha + \frac{1}{2} \dot{H}_S$. Using $\rho^E_i = (\dot{H}_i) - eV_\beta \rho^N_i$ (which comes from Eq. (24)) and summing over the sites $i$ in $L_\alpha$, we find with the help of Eqs. (40b) and (46)

$$I^H_\alpha (t) = Q_\alpha (t) + eN_\alpha \frac{\partial V_\alpha}{\partial t} - eV_\alpha I^N_\alpha (t).$$

$I^H_\alpha (t)$ is gauge invariant while the three terms on the right-hand side of Eq. (B3) are not. However in the t-Kwant gauge (52) in which the leads are time-independent, $I^H_\alpha (t) = Q_\alpha (t)$ where $Q_\alpha (t)$ is defined by Eq. (B1) upon replacing $\dot{H}$ by the gauge-transformed Hamiltonian $\dot{H}$ given in Sec. IV A. Thereby we recover Eq. (48).

As a side note, let us add that the counterpart of the proof given below does not require to work in the t-Kwant gauge (52).

We prove Eq. (51a) in two steps. We focus first on the particle current for this static problem is given by Eq. (63)

$$I^N_{ji} (t) = \sum_{\beta \neq i} \int \frac{dE}{h} f_{\beta + eV_\beta, T_\beta} (E) \times \text{Im} \left[ (\Psi^{m_\beta E, \tilde{\alpha}}_j)^* H^{\tilde{\alpha}}_{ji} \Psi^{m_\beta E, \tilde{\alpha}}_i \right].$$

where $\Psi^{m_\beta E, \tilde{\alpha}}_i$ is the stationary scattering state at site $i$ corresponding to an incoming mode $m_\beta$ in lead $L_\beta$ with energy $E$ i.e.

$$H^{\tilde{\alpha}}_i \Psi^{m_\beta E, \tilde{\alpha}}_i = E \Psi^{m_\beta E, \tilde{\alpha}}_i.$$ (C2)

Note that the static electric potential $V_\beta$ is included in the leads (i.e. $H^{\tilde{\alpha}}_i = H^0_i + eV_\beta$ if $i \in L_\beta$) and in the reservoirs through the Fermi-Dirac distribution. We now make use of the periodic pattern of each semi-infinite lead built of identical unit cells, labeled $x = 1, 2, \ldots$ from the scattering region. In the stationary case, the total particle current $I^N_{\tilde{\alpha}} (t)$ in the lead $L_\alpha$ (given by Eqs. (38) and (C1)) is invariant along the lead axis and we have for any $x$

$$I^N_{\tilde{\alpha}} = -2 \sum_{\beta} \sum_{m_\beta} \int \frac{dE}{h} f_{\beta + eV_\beta, T_\beta} (E) \times \text{Im} \left[ (\Psi^{m_\beta E, \tilde{\alpha}}_{\alpha, x-1})^* W_\alpha \Psi^{m_\beta E, \tilde{\alpha}}_{\alpha, x} \right].$$ (C3)

$\Psi^{m_\beta E, \tilde{\alpha}}_{\alpha, x}$ being the scattering state in the $x$-th cell of the lead $L_\alpha$ corresponding to an incoming mode $m_\beta$ in lead $L_\beta$ with energy $E$ and $W_\alpha$ the coupling matrix connecting neighboring unit cells in $L_\alpha$. Using the notations of Ref. 23 we write the scattering state $\Psi^{m_\beta E, \tilde{\alpha}}_{\alpha, x}$ as a superposition of plane waves

$$\Psi^{m_\beta E, \tilde{\alpha}}_{\alpha, x} = \delta_{\alpha \beta} \frac{\epsilon^{\text{in}}_{m_\alpha}}{\sqrt{h_{\alpha m_\beta}}} e^{-ik^{\text{in}}_{m_\beta} x} + \sum_{m_\alpha} \frac{\epsilon^{\text{out}}_{m_\alpha}}{\sqrt{h_{\alpha m_\beta}}} e^{ik^{\text{out}}_{m_\alpha} x} S^{\alpha m_\beta}_{m_\alpha m_\beta}$$ (C4)

where the sum runs over the modes $m_\alpha$ in lead $L_\alpha$. The vectors $\epsilon^{\text{in}}_{\alpha, m_\alpha} (E)$ and $\epsilon^{\text{out}}_{\alpha, m_\alpha} (E)$ defined on one unit cell are the transverse parts of the incoming and outgoing modes $m_\alpha$ with energy $E$ in lead $L_\alpha$. $k^{\text{in}}_{m_\alpha} (E)$, $k^{\text{out}}_{m_\alpha} (E)$, and $v^{\alpha}_{\alpha, m_\alpha} (E)$, $v^{\alpha}_{\alpha, m_\alpha} (E)$ are the corresponding mode momenta and velocities. $S^{\alpha m_\beta}_{m_\alpha m_\beta} (E)$ is the scattering amplitude of an electron injected at energy $E$ from the lead $L_\beta$ in mode $m_\beta$ into the mode $m_\alpha$ in lead $L_\alpha$. By inserting Eq. (C4) into Eq. (C3) and by using the relations

$$i (\epsilon^{\text{in}}_{m_\alpha})^* \epsilon^{\text{in}}_{m_\alpha} = \delta_{m_\alpha m_\beta} h_{\alpha m_\beta}$$ (C5)

$$i (\epsilon^{\text{out}}_{m_\alpha})^* \epsilon^{\text{out}}_{m_\alpha} = \delta_{m_\alpha m_\beta} h_{\alpha m_\beta}$$ (C6)

$$i (\epsilon^{\text{out}}_{m_\alpha})^* \epsilon^{\text{in}}_{m_\alpha} = 0$$ (C7)

it can be shown that $I^N_{\tilde{\alpha}}$ reduces to the standard Landauer-Büttiker formula

$$I^N_{\alpha} (t) = \sum_{\beta \neq \alpha} \int \frac{dE}{h} \tilde{T}_{\alpha \beta} (E) \left[ f_{\beta + eV_\alpha, T_\alpha} (E) - f_{\beta + eV_\beta, T_\beta} (E) \right]$$ (C8)

where $\tilde{T}_{\alpha \beta} = \sum_{m_\alpha} \sum_{m_\beta} |S^{\alpha m_\beta}_{m_\alpha m_\beta}|^2$. 

### Appendix C: Convergence to the static limit

We assume that the Hamiltonian $\dot{H} (t)$ defined in Sec. II converges to a static limit $\dot{H} (t \to \infty) = \dot{H}^{\tilde{\alpha}}$ at long times. We derive Eq. (51b) with the help of Eqs. (63) and (65) upon omitting the tildes in those equations since the proof given below does not require to work in the t-Kwant gauge (52).

#### 1. Particle current

We prove Eq. (51a) in two steps. We focus first on the static problem defined by $\dot{H}^{\tilde{\alpha}}$ for all times. The local particle current for this static problem is given by Eq. (63)
Let us now consider the time-dependent problem defined by $\hat{H}(t)$. In that case, the local particle current $I_{ji}^N(t)$ given by Eq.\{63\} reads

$$I_{ji}^N(t) = 2 \sum_{\beta} \sum_{m_{\beta}} \int \frac{dE}{\hbar} f_{\mu_{\beta},T_\beta}(E) \left[ \Psi_j^{m_{\beta},E}(t)^* H_{ji}(t) \Psi_i^{m_{\beta},E}(t) \right].$$

(C9)

To calculate $I_{ji}^N(t \to \infty)$ using $\dot{H}(t \to \infty) = \dot{H}^{\text{st}}$, it is important to notice first that $E$ in the equation above labels the energy of an incoming mode $m_{\beta}$ in lead $L_{\beta}$ in the remote past i.e. for $t \leq t_0$. In that case, the on-site potential in $L_{\beta}$ is $H_{ii}(t \leq t_0) = H_{ii}^0$ while $H_{ii}^{\text{st}} = H_{ii}^0 + \epsilon_{\beta}$ (if $i \in L_{\beta}$). For this reason,

$$e^{i\theta_E(t)} \Psi_j^{m_{\beta},E}(t) \xrightarrow{t \to \infty} \Psi_j^{m_{\beta},E+E_{\beta},st}$$

(C10)

where $\theta_E(t)$ is an (irrelevant) spatially constant phase. Doing the change of variable $E' = E + \epsilon_{\beta}$ in Eq.\{C9\} and comparing with Eq.\{C11\}, we find $I_{ji}^N(t \to \infty) = I_{ji}^{N,st}$. We deduce Eq.\{51a\} by using Eqs.\{38\} and \{C8\}.

### 2. Energy current

Let us consider first the static problem defined by $\hat{H}^{\text{st}}$ for all time. For this static problem, we define the energy operator as $\hat{\epsilon} = \hat{H}^{\text{st}}$. With this definition, the local energy current given by Eq.\{65\} simplifies to

$$I_{ji}^{E,st} = 2 \sum_{\beta} \sum_{m_{\beta}} \int \frac{dE}{\hbar} f_{\mu_{\beta},+\epsilon_{\beta},T_\beta}(E) E \left[ \Psi_j^{m_{\beta},E,st}(t)^* \Psi_i^{m_{\beta},E,st}(t) \right]$$

(C11)

after using the static Schrödinger equation (C2). To calculate the energy current $I_{ji}^{E,st}$ in the lead $L_{\alpha}$ with Eq.\{22\}, it is convenient to redefine the scattering region $S$ as we did previously to write down Eq.\{C3\} by including into it the first cell $x = 1$ of $L_{\alpha}$ (or an arbitrary number of cells $x = 1, 2, \ldots$). This does not change $I_{ji}^{E,st}$ as the static energy current calculated with $\hat{\epsilon} = \hat{H}^{\text{st}}$ is invariant along the lead axis. By using Eqs.\{C11\} and \{C4\}-\{C7\}, we find

$$I_{ji}^{E,st} = \sum_{\beta \neq \alpha} \int \frac{dE}{\hbar} E \hat{T}_{\alpha\beta}(E)$$

$$\times \left[ f_{\mu_{\alpha}+\epsilon_{\alpha},T_{\alpha}}(E) - f_{\mu_{\beta}+\epsilon_{\beta},T_{\beta}}(E) \right].$$

(C12)

Note that Eq.\{C12\} is the usual Landauer-Büttiker formula for the lead energy current in the static case, which we recovered upon defining in this case the energy operator as $\hat{\epsilon} = \hat{H}^{\text{st}}$.

Let us consider on the other hand the time-dependent problem defined by $\dot{H}(t)$. The energy operator is now defined by Eq.\{24\}. Using Eqs.\{63\}, \{C10\}, and finally \{C2\}, we find for the local energy currents in the long time limit

$$I_{ji}^{E}(t \to \infty) = I_{ji}^{E,st} - \frac{e}{2}(V_i + V_j)I_{ji}^{N,st}$$

(C13)

where $V_i \equiv V_i(t \to \infty)$ is a shorthand notation for the long time limit of the external time-dependent scalar potentials $V_i(t)$. We deduce from Eq.\{42b\}

$$I_{\alpha}^{E}(t \to \infty) = I_{\alpha}^{E,st} - eV_\alpha I_{\alpha}^{N,st} + S_{\alpha}^{E}(t \to \infty)$$

(C14)

since $V_i = V_\alpha$ if $i \in L_{\alpha}$ and $\frac{\partial \phi_{\alpha}}{\partial t} \to 0$ in the static limit $t \to \infty$. This concludes the proof of Eq.\{51b\}.

### Appendix D: Resonant Level Model within the Non Equilibrium Green’s Function formalism

In this appendix, we give the RLM formula for the lead particle current $I_{\alpha}^{L}(t)$ and the lead heat currents $I_{\alpha}^{H}(t)$, $\dot{I}_{\alpha}^{H}(t)$ that are used in Fig.1 to plot the NEGF curves. The model under consideration is the one introduced in Sec.\{V\}A with $\epsilon_{0}(t) = \epsilon_{0} + eV_\alpha(t)$ and $\epsilon_{i}(t) = \epsilon_{i}(t) = 0$. The lead Hamiltonians $\hat{H}_\alpha$ and the tunneling Hamiltonians between the dot and the leads $\hat{H}_{\alpha\beta}$ are written in the reciprocal space, as

$$\hat{H}_\alpha = \sum_{k_\alpha} \epsilon_{k_\alpha} \hat{c}_{k_\alpha}^\dagger \hat{c}_{k_\alpha}$$

(D1)

$$\hat{H}_{\alpha\beta} = \sum_{k_\alpha} V_{k_\alpha} \hat{c}_{k_\alpha}^\dagger \hat{c}_{0} + h.c.$$

(D2)

where $\hat{c}_{k_\alpha} = \sum_{j \in \alpha} e^{ijk_\alpha} \hat{c}_j$ is the annihilation operator of an electron with momentum $k_\alpha$ in lead $\alpha = L$ or $R$, $V_{k_\alpha} = \gamma_\alpha \sin(k_\alpha)$ the hybridization term, and $\epsilon_{k_\alpha} = -2\gamma_\alpha \cos(k_\alpha)$ the dispersion relation (with a lattice spacing fixed to unity). Then the currents are calculated within the NEGF formalism under the wideband limit approximation, i.e. assuming that $\Gamma_{\alpha}(E) = -2\text{Im}\Sigma_{\alpha}(E) = 2\pi \sum_{k_\alpha} |V_{k_\alpha}|^2 \delta(E - \epsilon_{k_\alpha})$ is energy independent ($\Gamma_{L} = \Gamma_{R} = \Gamma/2$). This is true in the limit $\lambda\gamma/\Gamma \gg 1$ as noticed in Sec.\{V\}B. We refer to the seminal paper\{12\} of Jauho et al. for the derivation of the particle current and to Refs.\{39\}-\{42\} for its extension to the energy and heat currents. We gather here the results. Introducing the notations $\hat{K}_{\alpha}^N = \hat{N}_\alpha = \sum_{k \in \alpha} \hat{c}_{k}^\dagger \hat{c}_k$, $\hat{K}_{\alpha}^E = \hat{H}_\alpha + \frac{1}{2} \hat{H}_{\alpha\beta}$, and $\hat{K}_{\alpha}^{\text{st}} = \hat{H}_{\alpha}$, we have for $\lambda = N$, $E$ and $\dot{E}$

$$\left\langle \frac{d\hat{K}_{\alpha}^{\lambda}}{dt} \right\rangle = \sum_{\beta} \int \frac{dE}{2\pi} f_{\beta}(E) \hat{T}_{\alpha\beta}(E,t)$$

(D3)
Computation time

\[ T_{\alpha\beta}(E, t) = \frac{1}{\hbar} \sum_{\alpha} A(E, t)|A(E, t)|^2 + \delta_{\alpha\beta}\text{Im}A(E, t) \]  
(D4)

\[ T_{\alpha\beta}^E(E, t) = E T_{\alpha\beta}(E, t) + \frac{\Gamma^E}{4}\delta_{\alpha\beta}\text{Im}[A(E, t)\frac{\partial A}{\partial t}](E, t)] \]  
(D5)

\[ T_{\alpha\beta}^E(E, t) = T_{\alpha\beta}^E(E, t) + \frac{\Gamma}{2}\delta_{\alpha\beta}\text{Re}\left[\frac{\partial A}{\partial t}(E, t)\right] \]  
(D6)

while the spectral density \( A(E, t) \) reads

\[ A(E, t) = \frac{E - \epsilon_0 + i\frac{\Gamma}{2} - eV_0 e^{i(E - \epsilon_0 - eV_0 + i\frac{\Gamma}{2})/\hbar}}{(E - \epsilon_0 + i\frac{\Gamma}{2})(E - \epsilon_0 - eV_0 + i\frac{\Gamma}{2})}. \]  
(D7)

We used the formula above to plot the NEGF particle current \( I_{\alpha}^H(t) = -\langle \frac{dN_{\alpha}}{dt} \rangle \) and the NEGF heat currents

\[ I_{\alpha}^H(t) = -\langle \frac{dN_{\alpha}}{dt} \rangle - \mu_{\alpha}(\frac{dN_{\alpha}}{dt}) \]  

and \( \tilde{I}_{\alpha}^H(t) = -\langle \frac{dN_{\alpha}}{dt} \rangle - \mu_{\alpha}(\frac{dN_{\alpha}}{dt}) \rangle \) in Fig. [4] (circles). The integrals over the energy were computed numerically.

Appendix E: Energy-related functionalities in the t-Kwant software: overview and performance

To calculate our newly defined energy related quantities, we have implemented additional Cython classes in t-Kwant under the `operator.energy` module.

Density, Source and CurrentDivergence can be called for calculating respectively \( \rho_i^E, S_i^E \), and \( \sum_{j\neq i} I_{ji}^E \) over a given list of sites \( \{i\} \); Current for calculating the current \( I_{\alpha}^E(t) \) flowing through a given list of hoppings between sites \( \{(j, i)\} \); LeadHeatCurrent for calculating the heat current \( I_{\alpha}^H(t) \) in a given lead \( \alpha \). Since the classes that are called to evaluate the particle and energy operators all have a similar structure, another class generalizing the former ones has also been implemented but not yet used.

The calculation of the many-body expectation values of the various operators involves an integration over the energy \( E \) and a sum over the modes \( m_\alpha \) injected at this energy from all the leads \( \mathcal{L}_\alpha \). Since the resolution of the Schrödinger-like differential equation (61) giving the evolution in time of the scattering states \( \Psi_{\text{scat}}^E(t) \) is the most time-consuming task of the t-Kwant algorithm (see below), it is crucial to use as few scattering states as possible to evaluate the expectations values. For this purpose, a Gauss-Kronrod adaptive scheme is used when integrating the contribution of each state over the energy. It determines the needed number \( N_{\text{scat}} \) of scattering states for a given precision on the expectation values. Moreover, the time-evolution of the scattering states can be done in parallel on multi-core computers, each core dealing with a subset of the scattering states. Both functionalities implemented in the core version of t-Kwant are leveraged to compute the expectation values of the energy operators.

Hereafter, we analyse the extra CPU time cost due to the evaluation of the energy operators. Given that the computation times for evolving the scattering states (between times \( t_{n-1} \) and \( t_n \)) and for calculating a many-body expectation value (at a time \( t_n \)) grow linearly with the total number \( N_{\text{scat}} \) of scattering states, we compare these two computation times for only one wave function \( \Psi \). The wave function is initialized (at \( t_0 = 0 \)) with uniformly distributed random complex values on each system site, in the \([-1, 1] \times [-i, i]\) complex square. The computation time for the stationary problem, done once for a given system, is not considered here. Investigations of the t-Kwant CPU times are done for a closed (i.e. without leads) square system with \( N = L^2 \) sites lying on a square lattice. The onsite potential \( H_{ii} \) is disordered and shifted by a time-dependent perturbation for \( t \geq t_1 \) as

\[ H_{ii}(t > 0) = w_i + \Theta(t - t_1)[\sin(\alpha t)e^{-\beta t^2} + \eta(1 + \tanh(\delta t))] \]  
(E1)

where \( t_1 = 0.8, \alpha = 8, \beta = 15, \eta = 0.3, \delta = 10, \) and \( w_i \) are random values that are normally distributed around zero with a standard deviation of 0.025. Hopping terms between sites \( i \neq j \) are fixed to \( H_{ij} = \gamma (=1) \) up to the \( z \)-th nearest neighbors and are zero beyond. Each site \( i \) thus have \( M_z \) connected neighbors. We note \( M_z = \sum_i M_i^z \).

In Fig. 4 we compare the computation times used for making the wavefunction \( \Psi(t) \) evolve by a time step and for calculating its contribution to the various particle and energy operators. Its contribution reads for instance

\[ \sum_j \text{Re}[\Psi_i^* \epsilon_{ij} \Psi_j] \]  

for the energy density operator evaluated on site \( i \) (see Eq. (61)). Each point in Fig. 4 is ob-
tained by averaging the computation times of 200 measurements performed at times $t_n$ (or over the intervals $[t_n, t_{n+1}]$) for the evolution of $\Psi(t)$ evenly spaced between $t_0 = 0$ and $t_{\text{max}} = 2$. CPU times are expressed in seconds and result from simulations run on a single core (Intel Xeon Silver 4114 CPU @ 2.20GHz, 32 Go RAM).

We check on the left panel of Fig.4(i) that the CPU time used for evolving a wavefunction by a time step grows linearly with the number of sites $N$ (as already reported in Refs. [25,26]), and (ii) that the CPU times corresponding to the computation of the contributions to the various operators grow linearly with the size of the lists of sites or hoppings on which they are calculated. The relative positions of the straight lines in this panel (obtained for $z = 1$) show us that it takes (much) longer to calculate the energy operators than the particle ones (which is obvious in view of the mathematical expression of the operators) but that the global CPU time used by the simulation is nevertheless dominated by the calculation of the wavefunction evolution. In the right panel of Fig.4 we investigate how this picture is modified when second ($z = 2$), third ($z = 3$), and fourth ($z = 4$) nearest-neighbors are included. The CPU time used for the wavefunction evolution is unaffected (except for $z = 4$ due to unknown – probably memory – reasons), as well as the CPU time corresponding to the particle density and the CPU time per hopping corresponding to the particle current. On the contrary, the CPU times corresponding to the energy operators are much increased since their expressions involve a sum over neighboring sites. It is to be noted at that stage that often, in practice, the operators only need to be calculated on a subsystem while the wavefunction has to be calculated necessarily over the $N$ sites of the system. For instance, the lead (particle, energy, heat) currents are calculated at the interface between the leads and the scattering region which involves a negligible number of hoppings in comparison to the total number $M_L/2$ of hoppings in the system. For this reason, we conclude that evaluating operators has a low-to-negligible impact on the global t-Kwant computation time for most practical situations. For Completeness, let us add that the CPU times needed for evaluating the operators and evolving the scattering states depend at a quantitative level on the simulated systems and on the hardware used. Additional (not shown) data indicate that this should not affect qualitatively the conclusion given above.
The set of fixed parameters corresponds to the one used in Ref.\textsuperscript{92}.

Eqs. (64) and (65) for \(\rho^N_i\) and \(I^N_i\), as well as their counterparts for \(\rho^E_i\) and \(I^E_i\), can be derived in the wave-function formalism, without invoking the lesser Green’s function. The proof goes in two steps. We start from the one-body problem in the continuum\textsuperscript{119} and discretize on a lattice the probability density \(\rho^N(r, t) = \psi^* \psi\), the probability current density \(j^N(r, t) = \text{Re}[\psi^* \nabla \psi]\), the energy density \(\rho^E(r, t) = \text{Re}[\psi^* \varepsilon \psi]\), and the (symmetrized) energy current density \(j^E(r, t) = \frac{1}{2} \text{Re}[\{\varepsilon \psi^* \} \{\varepsilon \psi\} + \psi^* \varepsilon \psi]\), where \(\psi(r, t)\) is the particle wave-function, \(\varepsilon = (-i \hbar \nabla - eA)/m\) the velocity operator and \(\varepsilon(r, v, t)\) the energy operator of the one-body continuous problem. Those quantities satisfy the continuity equations \(d\rho^N/dt + \nabla \cdot j^N = 0\) and \(d\rho^E/dt + \nabla \cdot j^E = e \cdot j^N \cdot E\). Thereby we obtain the one-body contributions of \(\rho^N_i, I^N_i, \rho^E_i\), and \(I^E_i\) by identifying \(\nabla \cdot j^N[k]\) with the one-body part of \(\sum_{j \neq i}^{} I^N_j[k]\). Then, the full \(\rho^N_i, I^N_i, \rho^E_i,\) and \(I^E_i\) corresponding to the many-body (non-interacting) problem are deduced by filling up the one-body states according to the Fermi-Dirac statistics.

We implemented additionally a general operator Cython class that can be used to calculate quantities of the form

\[
\sum_{\{i_0, \ldots, i_{n+1}\}} \phi_{i_0} O^{(0)}_{i_0i_1} O^{(1)}_{i_1i_2} \cdots O^{(n)}_{i_ni_{n+1}} \psi_{i_{n+1}} \pm \text{c.c.}
\]

where \(\phi(t)\) and \(\psi(t)\) are wavefunctions calculated by t-Kwant. \(O^{(0)}(t), \ldots, O^{(n)}(t)\) and \((i_0, \ldots, i_{n+1})\) are respectively quadratic operators and tuple of sites in \(S\) that are to be defined when using the class. Subclasses inheriting from this general class can be easily implemented to define \(e.g.\) the particle and energy operators or other operators enabling the computation of correlation functions. It comes however at the cost of an unfriendly implementation of the general class and of (slightly) longer computation times (when used for the particle and energy operators, in comparison to the direct implementation).
