A double power-law fit to the computed stellar log(τ/y)-log(m/m⊙) relation

R. Caimmi*

April 30, 2015

Abstract

The computed log(τ/y)-log(m/m⊙) relation for the stellar initial mass range, 0.6 ≤ m/m⊙ ≤ 120.0, and the stellar initial metallicity range, 0.0004 ≤ Z ≤ 0.0500, tabulated in an earlier attempt (Portinari et al. 1998) is fitted to a good extent by a four-parameter curve, expressed by a double power-law, for assigned stellar initial metallicity, which can be reduced to a three-parameter curve, expressed by a single power-law, for the whole set of stellar initial metallicities. The relative errors, R[log(τ/y)] = 1−log(τfit/y)/log(τ/y), do not exceed about 2% and 4%, respectively. The extent to which the interpolation curve, expressed by a single power-law, can be extrapolated towards both high-mass and low-mass stars, is also investigated. High-mass star lifetimes are understimated by a factor less than 2 up to m/m⊙ = 1000 and by a fiducial factor less than 4 up to m/m⊙ → +∞. Low-mass star lifetimes are overestimated by a factor of about 3 down to m/m⊙ = 0.25 and by an unacceptably large factor down to m/m⊙ = 0.08. The interpolation curve, expressed by a single power-law, is related (in differential form) to a generalization of the equation of the exponential decay, which could be the starting point for a theoretical interpretation. As a simple application, the star mass fraction of a single star generation with stellar initial mass function defined by a power-law, is plotted vs. the logarithmic stellar lifetime. The star

mass fraction declines in time at a decreasing rate for mild stellar initial mass function and at an increasing rate for steep stellar initial mass function, where a linear trend is exhibited for a value of the exponent close to the Salpeter's value ($p_{\text{lin}} \approx -2.35$).

*keywords - stars: evolution - stars: formation.*
1 Introduction

For isolated stars, the stellar lifetime is defined as the time needed to move from the zero-age main sequence up to the giant branch and through any subsequent giant evolution. There is no easy way to infer stellar lifetime as a function of stellar initial mass, from a selected star sample belonging to an assigned population. Accordingly, $\tau - m$ or $\log(\tau/y) - \log(m/m_\odot)$ relations, where $\tau$ is the stellar lifetime and $m$ the stellar initial mass, are interpolation curves to the results from stellar evolution models (e.g., Maeder and Meynet 1989; Padovani and Matteucci 1993). For further details, an interested reader is addressed to recent overviews (e.g., Romano et al. 2005).

A systematic dependence of the $\log(\tau/y) - \log(m/m_\odot)$ relation on the stellar initial metallicity, $Z$, is available in tabular form within the mass range, $0.6 \leq m/m_\odot \leq 120.0$, and the initial metallicity range, $0.0004 \leq Z \leq 0.0500$, where the changes due to different initial metallicities can be neglected to a first extent (Portinari et al. 1998). Accordingly, lifetime is a strongly decreasing function of the initial mass and only weakly dependent on the initial metallicity (e.g., Wiersma et al. 2009).

Interpolating the computed $\log(\tau/y) - \log(m/m_\odot)$ relation via a simple, continuous, derivable curve, could be useful in problems where the first derivatives, $d\tau/dm$ or $dm/d\tau$, and higher order derivatives are needed, such as chemical evolution models. The current note focuses on a computed $\log(\tau/y) - \log(m/m_\odot)$ relation where the dependence of stellar lifetime on stellar initial mass and metallicity is exploited (Portinari et al. 1998), aiming to the expression of four-parameter curves involving a double power-law, more specifically an exponential whose argument is, in turn, a power.

To this respect, using standard regression techniques seems to be inappropriate, in that different stellar evolution models yield different results for an assigned choice of input parameters, due to still persisting uncertainties on some physical processes, and standard regression curve procedures would be of little significance in the case under discussion. Then a different strategy must be exploited, where four “crossing” points are specified as belonging to the interpolation curve.

With regard to a fixed stellar initial metallicity, the coordinates of the crossing points can coincide with computer outputs, $[\log(m_U/m_\odot), \log(\tau_U/y)]$, $U = 0, A, B, C$, to be fixed as appropriate. With regard to the whole set of initial metallicities for which the results are available, the ordinates of the crossing points can be determined as average values of their counterparts related to the whole set of initial metallicities, while abscissae remain unchanged, $[\log(m_U/m_\odot), \log(\tau_U/y)]$, $U = 0, A, B, C$, to be fixed as appropriate, where $\log(\tau_U/y) = [\log(\tau_U/y)_1 + ... + \log(\tau_U/y)_N]/N$ and $N = 5$ in
the case under discussion (Portinari et al. 1998).

Four-parameter interpolation curves, for both selected initial metallicities and the whole set of initial metallicities, are derived in section 2. The results are presented in section 3. An illustrative application is shown in section 4. The discussion and the conclusion are performed in section 5.

2 Four-parameter interpolation curves

A complete set of computed stellar lifetime within the initial mass range, \(0.6 \leq m/m_\odot \leq 120.0\), and the initial metallicity range, \(0.0004 \leq Z \leq 0.0500\), is available in tabular form (Portinari et al. 1988). More specifically, stellar evolution has been computed for 30 stellar initial masses, where 15 lie within the range, \(0.6 \leq m/m_\odot \leq 2.0\), 7 within the range, \(2.5 \leq m/m_\odot \leq 9.0\), 6 within the range, \(12.0 \leq m/m_\odot \leq 60.0\), with the addition of \(m/m_\odot = 100.0, 120.0\); initial metallicities have been fixed to \(Z_1 = 0.0004, Z_2 = 0.0040, Z_3 = 0.0080, Z_4 = 0.0200, Z_5 = 0.0500\). It is worth noticing \(Z_4\), initially conceived as solar value, is supersolar according to a recent investigation yielding \(Z_\odot = 0.134\) (Asplund et al. 2009).

The computed \(\log(\tau/\text{yr})-\log(m/m_\odot)\) relation, listed in tabular form in an earlier attempt (Portinari et al. 1998), is plotted in Fig. 1 where different symbols relate to different initial metallicities: \(Z_1\) - crosses; \(Z_2\) - diamonds; \(Z_3\) - triangles; \(Z_4\) - squares; \(Z_5\) - saltires.

The interpolation of the results shall be performed via four-parameter curves defined as (Caimmi 2014):

\[
y = f(x) = C_1 \exp(-C_2 x^\gamma) + C_3 \quad ; \quad x \geq 0 \ ; \quad (1)
\]

where \(C_1, C_2, C_3, \gamma\), are parameters to be determined by fitting to a good extent.

Regression curves based on standard methods, such as least squares procedure, could be of little significance in that different stellar evolution codes with same input parameters yield different results, due to still persisting uncertainties on specific details of stellar evolution theory.

For this reason, a different strategy shall be adopted, namely interpolation curves are constrained to pass through four crossing points, \((x_0, y_0), (x_A, y_A), (x_B, y_B), (x_C, y_C)\), which implies the determination of the unknown parameters. More specifically, the substitution of the coordinates in Eq. (1) yields a system of four transcendental equations in four unknowns, \(C_1, C_2, C_3, \gamma\), as:

\[
y_0 = C_1 + C_3 \quad ; \quad x_0 = 0 \ ; \quad (2)
\]

\[
y_U = C_1 \exp(-C_2 x_U^{\gamma}) + C_3 \quad ; \quad U = A, B, C \ ; \quad (3)
\]
where \( x_0 = 0 \), for convenience.

The combination of Eqs. (1) and (2) yields:

\[
\frac{y - C_3}{C_1} = \frac{C_1 - y_0 + y}{C_1} = [\exp(-C_2)]^x > 0 ;
\]

which is equivalent to:

\[
C_2 = x^{-\gamma} \ln \left( \frac{C_1}{C_1 - y_0 + y} \right) ;
\]

where \( C_1 < 0 \) or \( C_1 > y_0 - y > 0 \) in the case under discussion.

The particularization of Eq. (5) to \((x_U, y_U), (x_V, y_V)\), after performing the ratio on both sides of related equations, produces:

\[
\left( \frac{x_V}{x_U} \right)^\gamma = \frac{\ln[(C_1 - y_0 + y_V)/C_1]}{\ln[(C_1 - y_0 + y_U)/C_1]} ;
\]

with the above mentioned restrictions for \( y_U, y_V \), to ensure positive argument of related logarithm. In the case under discussion, both \( x \) and \( \gamma \) are real, which implies the ratio on the right-hand side of Eq. (6) is non negative i.e. the arguments of the logarithms are both either larger or lower than unity.

The related condition reads:

\[
\max(y_U, y_V) < y_0 ; \quad \min(y_U, y_V) > y_0 ;
\]

which holds in the case under discussion, keeping in mind \( y_U < y_V < y_0 \) with no loss of generality, as shown in Fig. [1]

Taking the logarithm on both sides of Eq. (6) yields:

\[
\gamma \ln \frac{x_V}{x_U} = \ln \frac{C_1 - y_0 + y_V}{C_1} - \ln \frac{C_1 - y_0 + y_U}{C_1} ;
\]

where \( U = A; V = B, C \); with no loss of generality. The cross product of related equations reads:

\[
\ln \frac{x_C}{x_A} \left[ \ln \frac{C_1 - y_0 + y_B}{C_1} - \ln \frac{C_1 - y_0 + y_A}{C_1} \right] = \ln \frac{x_B}{x_A} \left[ \ln \frac{C_1 - y_0 + y_C}{C_1} - \ln \frac{C_1 - y_0 + y_A}{C_1} \right] ;
\]

which, in particular, can be solved for the crossing points, \((0, y_0), (x_A, y_A), (1, y_B), (2, y_C)\), where \( x_B = 1, x_C = 2 \), for convenience.
The intersection between the curve on the left and right-hand side of Eq. (9) yields the value of $C_1$. The value of $C_3$ can be readily inferred from Eq. (2) as:

$$C_3 = y_0 - C_1; \quad (10)$$

and the value of $C_2$ is determined via particularization of Eq. (3) to $(1, y_B)$. The result is:

$$C_2 = \ln \frac{C_1}{C_1 - y_0 + y_B}; \quad (11)$$

finally, $\gamma$ is determined via particularization of Eq. (8) to $U = A; V = B, C$. The result is:

$$\gamma = \left(\ln \frac{x_B}{x_C}\right)^{-1} \left[\ln \ln \frac{C_1 - y_0 + y_C}{C_1} - \ln \ln \frac{C_1 - y_0 + y_B}{C_1}\right]; \quad (12)$$

where $x_B/x_C = 1/2$ in the case under discussion.

With regard to interpolation curves related to selected stellar initial metallicities, the expression of the mathematical variables, $(x, y)$, in terms of the physical variables, $[\log(m/m_\odot), \log(\tau/y)]$, is constrained by the domain of the interpolation curve, defined by Eq. (1), $x \geq 0$, which implies the following:

$$x = \log \left(\frac{m}{m_\odot}\right) - \log \left(\frac{m_0}{m_\odot}\right); \quad y = \log \left(\frac{\tau}{y}\right); \quad (13)$$

where $m_0$ is the sample star exhibiting the lowest mass i.e. the longest lifetime, $m_0/m_\odot = 0.6$ in the case under discussion (Portinari et al. 1998). The crossing points can be explicitly expressed as: $P_0 \equiv [0, \log(\tau_{0.6}/y)],$ $P_A \equiv [-\log 0.6, \log(\tau_{1.0}/y)],$ $P_B \equiv [1, \log(\tau_{6.0}/y)],$ $P_C \equiv [2, \log(\tau_{60.0}/y)],$ where $\tau_{m/m_\odot}$ is the lifetime of a star with selected initial metallicity and initial mass equal to $m$ in solar units.

With regard to interpolation curves related to ordinates of crossing points averaged over the whole set of stellar initial metallicity, the expression of the mathematical variables, $(x, y)$, in terms of the physical variables, $[\log(m/m_\odot), \log(\tau/y)]$, for the abscissa, $x$, is provided by Eq. (13), while the ordinate, $y$, reads:

$$y = \log \left(\frac{\tau}{y}\right) = \frac{1}{5} \sum_{i=1}^{5} \log \left(\frac{\tau}{y}\right) Z_i; \quad (14)$$

where $Z_i, 1 \leq i \leq 5,$ are the stellar initial metallicities for which stellar evolution has been computed (Portinari et al. 1998). The crossing points can
be explicitly expressed as: $P_0 \equiv [0, \log(\tau_{0.6}/y)]$, $P_A \equiv [-\log 0.6, \log(\tau_{1.0}/y)]$, $P_B \equiv [1, \log(\tau_{6.0}/y)]$, $P_C \equiv [2, \log(\tau_{60.0}/y)]$. Within the stellar initial mass range under consideration, $0.6 \leq m/m_\odot \leq 120.0$, the stellar lifetime range reads $6 < \log(\tau/y) < 11$, which implies $y \gg 0$ via Eqs. (13) and (14). Accordingly, use can be made of the relative errors:

$$R(y) = 1 - \frac{y_{\text{fit}}}{y}; \quad (15)$$

where $y$ is inferred from computer output via Eq. (13) or (14), and $y_{\text{fit}}$ is the counterpart of $y$ on the related interpolation curve. The results are fitted to a good extent provided relative errors maintain small enough, within a few percent say.

3 Results

With regard to selected stellar initial metallicities, the interpolated $\log(m/m_\odot)$-$\log(\tau/y)$ relation is plotted in Fig. 1 as full curves, which exhibit negligible difference with the exception of the supersolar stellar initial metallicity, $Z = Z_5$, where slightly lower values are shown. A dotted horizontal line, $\log(\tau/y) = 8$, marks a conventional boundary between long-lived (up) and short-lived (down) stars, which could be of interest for simple chemical evolution models (e.g., Pagel and Patchett 1975; Caimmi 2011) and type Ia supernova progenitor models (e.g., Acharova et al. 2013).

The parameters of the interpolated $\log(m/m_\odot)$-$\log(\tau/y)$ relation, $C_1$, $C_2$, $C_3$, $\gamma$, are listed in Table 1. The parameters lie within narrow ranges, namely $4.92 < C_1 < 5.24$; $0.78 < C_2 < 1.00$; $5.49 < C_3 < 5.71$; $0.96 < \gamma < 1.06$. The special case, $\gamma = 1$, makes the interpolation curve reduce from a double power-law (an exponential whose argument is, in turn, a power) to a simple exponential. The interpolation curve related to averaged ordinates of crossing points and its reduction to a simple exponential, cases 6 and 7 of Table 1, are plotted in Fig. 1 as a dashed and a dotted curve, respectively.

The relative errors, $R(y)$, defined by Eq. (15), as a function of the logarithmic stellar initial mass, $\log(m/m_\odot)$, are plotted in Fig. 2 for interpolation curves related to both selected stellar initial metallicities, cases 1-5 of Table 1 (top panel) and averaged ordinates of crossing points, cases 6-7 of Table 1 (bottom panel), where different symbols are captioned as in Fig. 1. An inspection of Fig. 2 shows the relative errors do not exceed about 2% in the former alternative and less than 4% in the latter one. Then it may safely be thought interpolation curves, expressed by Eq. (14), with values of parameters listed in Table 1 satisfactorily fit to the computed $\log(\tau/y)$-$\log(m/m_\odot)$ relation.
Table 1: Parameters (p) of the interpolated log$(m/m_\odot)$-log$(\tau/\text{yr})$ relation, $C_1$, $C_2$, $C_3$, $\gamma$, for selected stellar initial metallicities, $Z = Z_1-Z_5$ with regard to cases (c) 1-5, and for ordinates of crossing points averaged over the whole set of stellar initial metallicity, case 6, with the addition of the special choice, $\gamma = 1$, leaving the remaining parameters unchanged, case 7. See text for further details.

| c | $Z$     | $C_1$     | $C_2$     | $C_3$     | $\gamma$  |
|---|---------|-----------|-----------|-----------|-----------|
| 1 | $Z_1$   | 5.10551   | 0.785151  | 5.52594   | 0.96950   |
| 2 | $Z_2$   | 5.23694   | 0.784218  | 5.49141   | 0.96686   |
| 3 | $Z_3$   | 5.20510   | 0.824914  | 5.60580   | 0.98915   |
| 4 | $Z_4$   | 5.08428   | 0.904558  | 5.81444   | 1.03125   |
| 5 | $Z_5$   | 4.92130   | 0.995420  | 5.93483   | 1.05302   |
| 6 | $\bar{Z}$ | 5.07899   | 0.862584  | 5.70612   | 1.00322   |
| 7 | $\bar{Z}$ | 5.07899   | 0.862584  | 5.70612   | 1.00322   |

The special case, $\gamma = 1$, deserves further attention in that the interpolation curve reduces to a simple exponential via Eq. (11), as:

$$y = C_1 \exp(-C_2 x) + C_3; \quad (16)$$

and the substitution of Eq. (13) into (16) after some algebra yields:

$$\log \left( \frac{\tau}{\text{y}} \right) = C'_1 \left( \frac{m}{m_\odot} \right)^{-C'_2} + C_3; \quad (17)$$

$$C'_1 = C_1 \exp \left[ C_2 \log \left( \frac{m_0}{m_\odot} \right) \right] ; \quad \frac{m_0}{m_\odot} = 0.6; \quad C'_2 = \frac{C_2}{\ln 10}; \quad (18)$$

which implies stellar lifetime is expressed by a double power-law, more specifically an exponential whose argument is, in turn, a power, as:

$$\frac{\tau}{\text{y}} = \exp_{10} \left[ C'_1 \left( \frac{m}{m_\odot} \right)^{-C'_2} + C_3 \right]; \quad (19)$$

where the parameter values are:

$$C'_1 = 4.19439; \quad C'_2 = 0.374616; \quad C_3 = 5.70612; \quad (20)$$

according to case 7 listed in Table 1.

8
4 A simple application

With regard to a single star generation, let the stellar initial mass function be a power-law as:

\[ \phi \left( \frac{m}{m_\odot} \right) = A \left( \frac{m}{m_\odot} \right)^p ; \]  

(21)

where \( A \) is the star formation efficiency and \(-3 \leq p \leq -2\) for the cases of interest, in particular \( p = -2.35 \) relates to a classical investigation on the solar neighbourhood (Salpeter 1955).

By definition, \( dN = \phi(m/m_\odot) dm(m/m_\odot) \) is the number of stars born within the mass range, \( m/m_\odot \pm dm(m/m_\odot) / 2 \), and the initial mass of the star generation reads:

\[ M^*(0) = A m_\odot \int_{m_\text{mf}/m_\odot}^{m_\text{Mf}/m_\odot} \frac{m}{m_\odot} \left( \frac{m}{m_\odot} \right)^p \frac{dm}{m_\odot} ; \]  

(22)

where \( m_\text{Mf} \) and \( m_\text{mf} \) are the upper and lower stellar initial mass limit, respectively, in solar units.

The mass of the star generation (without stellar remnants) at the time, \( t = \tau(m/m_\odot) \), reads:

\[ M^* \left( \frac{\tau}{\text{y}} \right) = A m_\odot \int_{m_\text{mf}/m_\odot}^{m_\text{Mf}/m_\odot} \frac{m}{m_\odot} \left( \frac{m}{m_\odot} \right)^p \frac{dm}{m_\odot} ; \]  

(23)

where \( \tau(m/m_\odot) \) is the lifetime of a star of mass \( m \) in solar units.

The fractional mass of the star generation, \( s(\tau/\text{y}) = M^*(\tau/\text{y})/M^*(0) \), can be determined from Eqs. (22) and (23) after performing integration. The result is:

\[ s \left( \frac{\tau}{\text{y}} \right) = \frac{(m/m_\odot)^{2+p} - (m_\text{mf}/m_\odot)^{2+p}}{(m_\text{Mf}/m_\odot)^{2+p} - (m_\text{mf}/m_\odot)^{2+p}} ; \quad p \neq -2 ; \]  

(24a)

\[ s \left( \frac{\tau}{\text{y}} \right) = \frac{\ln(m/m_\text{mf})}{\ln(m_\text{Mf}/m_\text{mf})} ; \quad p = -2 ; \]  

(24b)

regardless of the star formation efficiency.

The fractional mass of a star generation, expressed by Eq. (24), is plotted in Fig.3 for \( p = -3.0, -2.9, \ldots, -2.0 \), from top to bottom, with regard to the interpolation curve expressed by a simple exponential, Eq. (16), case 7 of Table 1. Related stellar lifetimes, corresponding to the whole range for which stellar evolution has been computed in the parent paper (Portinari et al. 1998), are marked by dotted vertical lines where \( m_\text{mf}/m_\odot = 0.6 \) and
m_{Mf}/m_{\odot} = 120.0. A restricted number of stellar initial masses are captioned on the top of the box.

An inspection of Fig.3 shows the expected trend: mild stellar initial mass functions ($p \approx -2$) imply a larger fraction of short-lived stars and, in turn, a change in star mass fraction at a decreasing rate. On the other hand, steep stellar initial mass functions ($p \approx -3$) imply a larger fraction of long-lived stars and, in turn, a change in star mass fraction at an increasing rate. Interestingly, the transition case where the $s(\tau/y)\log(\tau/y)$ relation is linear, is close to the Salpeter’s value, $p = p_{\text{lin}} \approx -2.35$.

To gain more insight, the above mentioned special case relates to a straight line passing through the points, $[\log(\tau_{mf}/y), 0]$ and $[\log(\tau_{Mf}/y), 1]$, which can be expressed as:

$$s\left(\frac{\tau}{y}\right) = \frac{\log(\tau/y) - \log(\tau_{mf}/y)}{\log(\tau_{Mf}/y) - \log(\tau_{mf}/y)} ;$$  \hspace{1cm} (25)

where $\tau_{mf} = \tau(m_{mf})$, $\tau_{Mf} = \tau(m_{Mf})$, for brevity. The combination of Eqs. (24a) and (25), after little algebra, yields:

$$\log\left(\frac{\tau}{y}\right) = \frac{\log(\tau_{Mf}/y) - \log(\tau_{mf}/y)}{(m_{Mf}/m_{\odot})^{2+p} - (m_{mf}/m_{\odot})^{2+p}} \left(\frac{m}{m_{\odot}}\right)^{2+p}$$

$$- \frac{\log(\tau_{Mf}/y) - \log(\tau_{mf}/y)}{(m_{Mf}/m_{\odot})^{2+p} - (m_{mf}/m_{\odot})^{2+p}} \left(\frac{m_{mf}}{m_{\odot}}\right)^{2+p} + \log\left(\frac{\tau_{mf}}{y}\right) ;$$  \hspace{1cm} (26)

where $p = p_{\text{lin}}$ via Eq. (25).

The comparison of Eq. (26) with (17) term by term implies the validity of the following relations:

$$C_2' = -2 - p ;$$  \hspace{1cm} (27)

$$C_1' = \frac{\log(\tau_{Mf}/y) - \log(\tau_{mf}/y)}{(m_{Mf}/m_{\odot})^{2+p} - (m_{mf}/m_{\odot})^{2+p}} ;$$  \hspace{1cm} (28)

$$C_3 = -\frac{\log(\tau_{Mf}/y) - \log(\tau_{mf}/y)}{(m_{Mf}/m_{\odot})^{2+p} - (m_{mf}/m_{\odot})^{2+p}} \left(\frac{m_{mf}}{m_{\odot}}\right)^{2+p} + \log\left(\frac{\tau_{mf}}{y}\right) ;$$  \hspace{1cm} (29)

where, in the case under discussion, the left-hand side of Eqs. (27) - (29) is known via Eq. (20) and $m_{mf} = 0.6$, $m_{Mf} = 120.0$. Then $p = p_{\text{lin}}$ can be evaluated via Eqs. (20), (27), and Eqs. (28) and (29) are merely to be verified. The result is:

$$p_{\text{lin}} = -2.374616 ;$$  \hspace{1cm} (30)

where the values of $C_1'$ and $C_3$ coincide with their counterparts expressed by Eq. (20), as expected.
In conclusion, a star generation where the initial mass function is expressed by a power-law within the range, $0.6 \leq m/m_\odot \leq 120.0$, implies a linear dependence of the star mass fraction, $s(\tau/y)$, on the logarithmic stellar lifetime, $\log(\tau/y)$, for an exponent of the initial mass function close to Salpeter’s value, $p_{\text{lin}} \approx -2.35$.

## 5 Discussion and conclusion

Computed stellar $\log(\tau/y)-\log(m/m_\odot)$ relations are interpolated to a good extent by double power-laws and, in particular, by a single power-law, Eqs. (11) and (16), respectively, regardless of the initial stellar metallicity, within the stellar initial mass range, $0.6 \leq m/m_\odot \leq 120.0$. The case of a single power-law is especially attractive due to its simplicity over an extended mass domain.

By comparison, a $\log(\tau/y)-\log(m/m_\odot)$ relation can be used for massive $(m/m_\odot > 6.6)$ stars (e.g., Matteucci and Greggio 1986), while a cumbersome expression is necessary for less massive stars (e.g., Renzini and Buzzoni 1986). In alternative, four different $\log(\tau/y)-\log(m/m_\odot)$ relations can be used within the mass range, $1.3 \leq m/m_\odot \leq 120.0$ (Maeder and Meynet 1989). A three-parameter (depending on the stellar initial metallicity) fit to earlier results from the Padua group (Alongi et al. 1993; Bressan et al. 1993; Bertelli et al. 1994) is restricted to $Z \leq 0.03$ and the extrapolation does not reproduce the correct trend as $m/m_\odot \to +\infty$ (Raiteri et al. 1996).

With regard to the interpolation curve, expressed by Eq. (16), the following relations hold for stellar initial masses outside the domain of computed stellar evolution (Portinari et al. 1998) used in the current attempt:

\[
\log \left( \frac{\tau_0}{y} \right) \to +\infty ; \quad \frac{m}{m_\odot} \to 0 ; \quad (31)
\]

\[
\log \left( \frac{\tau_\infty}{y} \right) = C_3 = 5.70612 ; \quad \frac{m}{m_\odot} \to +\infty ; \quad (32)
\]

which is the correct trend, in the sense that (failed) stars with mass, $m/m_\odot < m_{\text{mf}}/m_\odot \approx 0.08$, never start hydrogen burning and related lifetime can be conceived as infinite. On the other hand, stars with increasingly high mass exhibit finite lifetime regardless of initial metallicity. The comparison between computed lifetimes (Portinari et al. 1998) and their counterparts inferred from the interpolation curve, expressed by Eqs. (16), (20), case 7 of Table 1 is shown in Table 2. It is apparent lifetimes calculated via the single power-law interpolation curve outside the domain towards high stellar masses are
Table 2: Comparison between computed stellar lifetimes (Portinari et al. 1998), $\tau_{Pa98}$, and their counterparts inferred from the single power-law interpolation curve, case 7 of Table 1, $\tau_7$, outside the domain towards high-mass stars. See text for further details.

| $m/m_\odot$ | $\tau_{Pa98}$/y | $\tau_7$/y |
|------------|----------------|-----------|
| 150        | 3.0E6          | 2.2286E6  |
| 200        | 2.7E6          | 1.9162E6  |
| 300        | 2.5E6          | 1.5894E6  |
| 500        | 2.0E6          | 1.3032E6  |
| 1000       | 2.0E6          | 1.0507E6  |
| $+\infty$  | 5.7061E5       |           |

underestimated with respect to computed values, by a factor not exceeding 2 up to $m/m_\odot = 1000$.

Concerning stars with decreasingly low mass, a similar comparison is shown in Table 3 where computed stellar lifetimes are from a different source (Laughlin et al. 1997), restricted to stellar initial metallicity, $Z = 0.02$ (Laughlin and Bodenheimer 1993). It is apparent lifetimes calculated via the single power-law interpolation curve outside the domain towards low stellar masses are unacceptably overestimated with respect to computed values but, interestingly, the discrepancy is within the same order of magnitude for $m/m_\odot = 0.25$, where stellar evolution still attains the giant phase (Laughlin et al. 1997). Accordingly, an absence of the giant phase would imply a different $\log(\tau/y)$-$\log(m/m_\odot)$ relation.

A simple but acceptable linear fit to the results listed in Table 3, leaving aside $m/m_\odot = 0.25$, reads:

$$\log \left( \frac{\tau}{y} \right) = -2 \log \left( \frac{m}{m_\odot} \right) + 10.8 ; \quad (33)$$

which implies $\log(\tau_{1.0}/y) = 10.800$ and $\log(\tau_{0.6}/y) = 11.257$, larger but of about the same order of magnitude with respect to their counterparts determined from stellar evolution (Portinari et al. 1998).

The computed $\log(\tau/y)$-$\log(m/m_\odot)$ relation, represented in Fig. 1, extended to the results listed in Tables 2 and 3, is shown in Fig. 4 where, in addition, the single power-law interpolation curve and the interpolation line, Eqs. (16), (20), and (33), respectively, are also plotted together with the asymptotic limit of the interpolation curve for infinite stellar initial mass. The global trend exhibited by the computed $\log(\tau/y)$-$\log(m/m_\odot)$ re-
Table 3: Comparison between computed stellar lifetimes (Laughlin et al. 1997), \( \tau_{\text{La97}} \), and their counterparts inferred from the single power-law interpolation curve, case 7 of Table 1, \( \tau_7 \), outside the domain towards low-mass stars. See text for further details.

| \( m/m_\odot \) | \( \tau_{\text{La97}}/y \) | \( \tau_7/y \) |
|---|---|---|
| 0.08 | 1.1E13 | 3.24E16 |
| 0.10 | 6.2E12 | 4.40E15 |
| 0.12 | 4.2E12 | 9.72E14 |
| 0.14 | 3.4E12 | 2.93E14 |
| 0.16 | 2.7E12 | 1.10E14 |
| 0.18 | 2.0E12 | 4.78E13 |
| 0.20 | 1.8E12 | 2.35E13 |
| 0.25 | 1.7E12 | 5.71E12 |

The question if the single power-law interpolation curve, expressed by Eqs. (16), (20), arises from a mere coincidence or has a theoretical interpretation, is outside the aim of the current attempt but some considerations can be performed. Differentiating both sides of Eq. (16), after little algebra yields:

\[
\frac{d\bar{\tau}}{d\eta\dot{\bar{\tau}}} = -\lambda \eta^{\beta} \dot{\bar{\tau}} ; \tag{34}
\]

\[
\dot{\bar{\tau}} = \frac{\tau}{y} ; \quad \eta\dot{\bar{\tau}} = \frac{m}{m_\odot} \lambda = C_1' C_2' ; \quad \beta = C_2' + 1 ; \tag{35}
\]

where the special case, \( \beta = 0 \), reduces to the equation of the exponential decay, \( \dot{\bar{\tau}} \) being related to the number of decaying nuclides and \( \eta\dot{\bar{\tau}} \) to the time.
Accordingly, Eq. (34) learns (i) longer stellar lifetimes imply larger change of stellar lifetime with stellar initial mass and vice versa, and (ii) higher stellar initial masses imply lower change of stellar lifetime with stellar initial mass and vice versa. In the author’s opinion, a theoretical explanation of Eq. (16) should necessarily start from the above mentioned points.

The fractional stellar mass as a function of the logarithmic stellar lifetime, shown in Fig. 3, relates to a single star generation and to a power-law stellar initial mass function, which are limiting cases. In reality, multiple star generations appear even in low-mass stellar systems and the stellar initial mass function exhibits a more complex trend with respect to a simple power-law. On the other hand, the ideal situation depicted in Fig. 3 is expected to show a similar trend with respect to the real case, at least for environments where the whole amount of pristine gas was turned into stars in a short time, less than 1 Gyr say, such as the inner halo, the thick disk, and globular clusters. It is worth noticing the stellar mass is less than the total mass, in that the contribution of stellar remnants (white dwarfs, neutron stars, black holes) and baryonic dark matter is neglected: in any case, the related contribution is expected to be of a few percent at most.

With regard to globular clusters with age equal to $\tau_{0.9}$ (first vertical line on the right of $\log(\tau/y) = 10$), an inspection of Fig. 3 shows a present star mass fraction, $0.07 \lesssim s \lesssim 0.35$, according if $-2 \geq p \geq -3$, in particular $s \approx 0.15$ for the Salpeter’s exponent, $p = -2.35$, close to a linear dependence of the star mass fraction on the logarithmic stellar lifetime. Then a mild stellar initial mass function, $p \approx -2.1$, implies an initial mass larger by a factor of about ten, for globular clusters with age equal to $\tau_{0.9}$, in the case under consideration.

The main results of the current note can be summarized as follows.

(1) The computed $\log(\tau/y)$-$\log(m/m_\odot)$ relation for the stellar initial mass range, $0.6 \leq m/m_\odot \leq 120.0$, and the stellar initial metallicity range, $0.0004 \leq Z \leq 0.0500$, tabulated in an earlier attempt (Portinari et al. 1998) is fitted to a good extent by a double power-law for assigned initial metallicity, which can be reduced to a single power-law for the whole set of initial metallicities. The relative errors, $R[\log(\tau/y)] = 1 - \log(\tau_{fit}/y)/\log(\tau/y)$, do not exceed about 2% for the double power-law and 4% for the single power-law.

(2) The interpolation curve, expressed by a single power-law, can be extrapolated towards both high-mass and low-mass stars. In the former alternative, stellar lifetimes are underestimated by a factor less than 2 up to $m/m_\odot = 1000$ (Portinari et al. 1998) and by a fiducial factor less
than 4 up to \( m/m_\odot \to +\infty \). In the latter alternative, stellar lifetimes are overestimated by a factor less than about 3 down to \( m/m_\odot = 0.25 \) and by an unacceptably large factor down to \( m/m_\odot = 0.08 \) (Laughlin et al. 1997).

(3) The first derivative, \( d(\tau/y)/d(m/m_\odot) \), related to the single power-law interpolation curve, is a generalization of the equation of the exponential decay, which could be the starting point for a theoretical interpretation of the \( \log(\tau/y) - \log(m/m_\odot) \) relation.

(4) In the special case of a single star generation with stellar initial mass function defined by a power-law, using the single power-law interpolation curve within the mass range, \( 0.6 \leq m/m_\odot \leq 120.0 \), the star mass fraction declines in time at a decreasing rate for mild stellar initial mass function \( (p \lesssim -2) \) and at an increasing rate for steep stellar initial mass function \( (p \approx -3) \), where a linear trend is exhibited for a value of the exponent close to the Salpeter’s value \( (p_{\text{lin}} \approx -2.35) \).

Figure 1: Computed $\log(\tau/y)-\log(m/m_\odot)$ relation for 30 different stellar initial masses within the range, $0.6 \leq m/m_\odot \leq 120.0$, in connection with 5 different stellar initial metallicities (Portinari et al. 1998). Different symbols relate to different metallicities as indicated. Four-parameter interpolation curves are shown as full for selected stellar initial metallicity; dashed for ordinates of crossing points averaged over the whole set of stellar initial metallicity; dotted for parameters, $C_1$, $C_2$, $C_3$, as in the last case and $\gamma$ set equal to unity. The dotted horizontal line marks a conventional boundary between long-lived (top) and short-lived (bottom) stars. See text for further details.
Figure 2: The relative error, $R(y) = 1 - \log(\tau_{\text{fit}}/y)/\log(\tau/y)$, as a function of the logarithmic stellar initial mass, $\log(m/m_\odot)$, with regard to interpolation curves related to selected stellar initial metallicity (top panel) and to averaged ordinates of crossing points (bottom panel). Different symbols correspond to different stellar initial metallicity as shown in Fig. 1. See text for further details.
Figure 3: Fractional mass of a star generation, $s(\tau/y) = M^*(\tau/y)/M^*(0)$, as a function of the logarithmic stellar lifetime, $\log(\tau/y)$, for a power-law stellar initial mass function with exponent equal to (from top to bottom) $p = -3.0, -2.9, ..., -2.0$, with regard to a computed $\log(\tau/y) - \log(m/m_\odot)$ relation interpolated by a simple exponential, restricted to the domain, $0.6 \leq m/m_\odot \leq 120.0$. Related stellar lifetimes, corresponding to the whole range for which stellar evolution has been computed (Portinari et al. 1998), are marked by dotted vertical lines, a restricted number of which are captioned on the top of the box.
Figure 4: Computed log(τ/y)-log(m/m⊙) relation, plotted in Fig. 4, extended to both lower (Laughlin et al. 1997) and larger (Portinari et al. 1998) stellar initial masses. Lower masses relate to stellar initial metallicities, Z = 0.02. An interpolation straight line and power-law curve, respectively, are also shown (dotted). The asymptotic limit of the interpolation curve towards infinite stellar initial mass is marked by a dotted horizontal line. See text for further details.
