(Dated: )

The relation between 3-cocycles arising in the Dirac monopole problem and nonassociative gauge transformations is studied. It is shown that nonassociative extension of the group U(1) allows to obtain a consistent theory of pointlike magnetic monopole with an arbitrary magnetic charge.

I. INTRODUCTION

In 1931 Dirac [1] introduced a magnetic monopole into the quantum mechanics and found a quantization relation between an electric charge $e$ and magnetic charge $q$, $2\mu = n$, $n \in \mathbb{Z}$, where $\mu = eq$, and $h = c = 1$. One of the widely accepted proofs of the Dirac selection rule is based on group representation theory (see, for example, [2, 3, 4, 5, 6]).

In the presence of the magnetic monopole the operator of the total angular momentum $J$, which includes contribution of the electromagnetic field, obeys the standard commutation relations of the Lie algebra of the rotation group

$$[J_i, J_j] = i\varepsilon_{ijk}J_k.$$ and this is true for any value of $\mu$. Notice that these commutation relations fail on the Dirac string, restricting the domain of definition of the operator $J$ and limiting it to the functions that vanish sufficiently rapidly on the string [4]. Here $J$ may be extended to self-adjoint operator satisfying the commutation relations of the rotation group for an arbitrary $\mu$ [5].

The requirement that $J_i$ generate a finite-dimensional representation of the rotation group yields $2\mu$ being integer and only values $2\mu = 0, \pm 1, \pm 2, \ldots$ are allowed. However, employing infinite-dimensional representations of the rotation group one can relax Dirac’s condition and obtain the consistent monopole theory with an arbitrary magnetic charge [2, 6, 7].

The situation with the translations in the background of the monopole is completely different from the rotations. Since the Jacobi identity fails for the gauge invariant algebra of translations they do not form the Lie algebra, and for the finite translations one has [10, 11, 12, 13]

$$(U_a U_b) U_c \Psi(r) = e^{i\alpha_3(r,a,b,c)} U_a (U_b U_c) \Psi(r) \quad (1)$$

where $\alpha_3$ is the so-called 3-cocycle. For the Dirac quantization condition being satisfied, one has $\alpha_3 = 0$ mod $(2\pi n)$; and Eq. (1) provides an associative representation of the translations, in spite of the fact that the Jacobi identity for the infinitesimal generators continues to fail. The 3-cocycles, besides being appeared in the Dirac monopole background, lead also to a nonassociative algebra of defects in quantum-mechanical systems and are related to axions in string theory [14, 15].

The low-dimensional cocycles are known also in modern physics in relation with the non-Abelian anomalies and Wess-Zumino action. For instance, the Wess-Zumino functional is identified as 1-cocycle and the anomalous Schwinger term as a 2-cocycle [16, 17, 18].

In this letter we introduce nonassociative gauge transformations and give a new interpretation of 3-cocycle linking it with the associator of the gauge loop. We argue that a nonassociative extension of the conventional group U(1) allows an arbitrary magnetic charge.

II. COCYCLES AND MAGNETIC MONOPOLE

Following [17] consider a group $G$ acting on a manifold $\mathcal{M}$ as a group of transformations: $x \to xg$, $x \in \mathcal{M}$, $g \in G$. For an array function $\alpha_n(x;g_1,\ldots,g_n)$, called the $n$-cochain, the coboundary operator $\delta$ is defined as

$$(\delta\alpha_n)(x;g_1,g_2,\ldots,g_{n+1}) = \alpha_n(xg_1;g_2,\ldots,g_{n+1}) - \alpha_n(x;g_1,g_2,\ldots,g_n+1) + \ldots + (-1)^n\alpha_n(x;g_1,\ldots,g_{n+1}), \quad (2)$$

and it is easy to check that $\delta^2 = 0$. A cochain $\alpha_n = \delta\alpha_n$ is called a coboundary, and if $\alpha_n$ satisfies $\delta\alpha_n = 0$, it is called a cocycle. A cocycle is nontrivial if it is not a coboundary, i.e. $\delta\alpha = 0$, but $\alpha \neq \delta\beta$. Notice, that the $n$-cochain can be associated with a differential $n$-form $\omega_n$ as

$$\alpha_n(x;g_1,g_2,\ldots,g_n) = \int_{\Sigma_n} \omega_n, \quad (3)$$

where $\Sigma_n$ is a $n$-simplex with vertices $(x,xg_1,\ldots,xg_1\ldots g_n)$.

The 1-cochain $\alpha_1(x;g)$ appears in the representation $U_g$ of the group $G$ in the space of the functions $\Psi(x)$ on
Associativity is fulfilled if the projective representation reduces to an ordinary one.

If \( \alpha_1(x; g) \) is a trivial cocycle,
\[
\alpha_1(x; g) = \delta \alpha_0(x; g) = \alpha_0(xg) - \alpha_0(x),
\]
then the representation reduces to the usual one
\[
U_g U_g \gamma(x) = U_{g_1} U_g \gamma(x),
\]
by the unitary transformation \( \gamma(x) \rightarrow \exp(i \alpha_0(x)) \gamma(x) \).

A 2-cocycle \( \alpha_2 = \delta \alpha_1 \) defined for a given 1-cocycle \( \alpha_1 \) by
\[
\alpha_2(x; g_1, g_2) = \alpha_1(xg_1; g_2) - \alpha_1(x; g_1g_2) + \alpha_1(x; g_1)
\]
appears in the product of two operators:
\[
U_g U_g \gamma(x) = e^{i \alpha_2(xg_1; g_2)} U_{g_1} U_g \gamma(x).
\]
When the 2-cocycle does not depend on \( x \), Eq. (8) provides a projective representation of the group \( G \), i.e.
\[
U_g U_g = e^{i \alpha_2(g_1; g_2)} U_{g_1} U_g.
\]
The condition of associativity for \( \alpha_3 \) yields \( \alpha_3 = 0 \), and for \( \alpha_2 \) being a trivial 2-cocycle the representation reduces to an ordinary one.

Let \( \alpha_2(x; g_1, g_2) \) be a 2-cocycle, then the 3-cocycle \( \alpha_3 = 0 \), is given by
\[
\alpha_3(x; g_1, g_2, g_3) = \alpha_2(xg_1; g_2, g_3) - \alpha_2(x; g_1g_2g_3) + \alpha_2(x; g_1g_2) \text{ if the monopole is enclosed by the simplexes with vertices being } \Gamma^1(r, r_1, r_2, r_3) \text{ or zero otherwise.}
\]

The cocycles allow to construct the realization of the group \( \text{String} \mathcal{M} \) in the space of complex functions on \( \mathcal{M} \) in the following way. Let \( \gamma \) be the gauge group of maps \( \lambda_\gamma : \mathcal{M} \rightarrow \text{U}(1), \gamma \in \text{String} \mathcal{M} \). Then the extension \( \text{String}^g \mathcal{M} \) is defined as the product of \( \text{String} \mathcal{M} \otimes \mathcal{M} \) with nonassociative multiplication
\[
\left( \gamma_1 \lambda_1 \right) \left( \gamma_2 \lambda_2 \right) = \left( \gamma_1 \gamma_2 \right) \left( \lambda_1 \lambda_2 \right),
\]
where \( \lambda_\gamma (r) = \lambda (r \gamma_1 (r)) \), and \( \lambda \) is a 1(1)-valued function on \( \mathcal{M} \) given by \( \lambda (r \gamma_1 (r)) \) for \( \gamma_1 (r) \). The realization of the group \( \text{String} \mathcal{M} \) is defined as follows:
\[
U_g \gamma \psi (r) = A_1 (r; \gamma) \psi (r), \quad U_g, \gamma \in \text{U}(1)
\]
where \( A_1 (r; \gamma) = \exp (i \alpha_1 (r; \gamma)) \), and the composition law for the two operators \( A_1 \) is taken to be
\[
A_1 (r; \gamma_1) A_1 (r; \gamma_2) = e^{i \alpha_2 (r; \gamma_1, \gamma_2)} A_1 (r; \gamma_1\gamma_2).
\]
The 2-cochain $\alpha_2$ enters in the product of the two operators $U_{g_1}$ as follows:

$$U_{g_1}U_{g_2}\Psi(r) = e^{i\alpha_2(r,\gamma_1,\gamma_2)}U_{g_{12}}\Psi(r). \quad (21)$$

The nonassociativity of multiplication is described by the 3-cocycle $\alpha_3$ which appears in the triple-product:

$$U_{g_1}(U_{g_2}U_{g_3})\Psi(r) = e^{i\alpha_3(r,\gamma_1,\gamma_2,\gamma_3)}(U_{g_1}U_{g_2})U_{g_3}\Psi(r).$$

Just as in Eq. (17) we find that $\alpha_3 = 4\pi\mu$ if the monopole is enclosed by the simplex with vertices being $(r,r_1,r_2,r_3)$ and zero otherwise. The obtained realization is called a nonassociative representation of the group. Associativity is fulfilled if $\alpha_3 = \delta\alpha_2 = 0 \mod (2\pi n)$ and leads to the Dirac’s quantization condition, $2\mu \in \mathbb{Z}$.

III. NONASSOCIATIVE GAUGE TRANSFORMATIONS

We start with some elementary facts from the theory of quasigroups and loops (see, e.g. [20, 21, 22]).

A set $(Q, \cdot)$ with a binary operation $(a, b) \mapsto a\cdot b$ where the equations $a = b, y\cdot a = b$ have unique solutions in $Q$ for all $a, b \in Q$, is called a quasigroup. A loop is a quasigroup with a two-sided identity, $a\cdot e = e\cdot a = a, \forall a \in Q$. A loop $(Q_{\cdot}, e)$ with a smooth functions $\phi(a, b) := a\cdot b$ is called a smooth loop. For $(Q_{\cdot}, e)$ being a local loop with a neutral element $e$ one has the following identity of quasiassociativity

$$a\cdot(b\cdot c) = (a\cdot b)\cdot c$$

where $l_{(a,b)}$ is an associator.

Let $(Q\mathcal{U}(1), \cdot, e)$ be the loop of multiplication by unit-modular complex numbers related with the group U(1) as follows: Let $U_g = \exp(i\theta)$, then we define the operation $\circ$ in QU(1) by

$$U_{g_1} \circ U_{g_2} = e^{i\alpha_2(g_1, g_2)}U_{g_{12}}, \quad (23)$$

$$U_{(g_1, g_2)g_3} = e^{i\Delta(g_1, g_2, g_3)}U_{g_3} \quad U_{g_1}, U_{g_2} \in QU(1), \quad (24)$$

where $U_{g_{12}} = U_{g_1}U_{g_2}$ denotes the conventional multiplication of the elements of the group U(1), $\alpha_2(g_1, g_2)$ is a 2-cochain; and $\Delta(g_1, g_2, g_3)$ will be specified below. Further we assume that the following commutation relations hold:

$$e^{i\alpha_2(g_1, g_2)}U_g = U_ge^{i\alpha_2(g_1, g_2)}, \quad (25)$$

$$e^{i\Delta(g_1, g_2, g_3)}U_g = U_{g}e^{i\Delta(g_1, g_2, g_3)}. \quad (26)$$

For the product of the three elements we find

$$U_{g_1}(U_{g_2}U_{g_3}) = e^{-i(\alpha_2(g_1, g_2) + \alpha_2(g_2, g_3))}U_{g_1} \circ (U_{g_2} \circ U_{g_3}),$$

$$(U_{g_1}U_{g_2})U_{g_3} = e^{-i(\alpha_2(g_1, g_3) + \alpha_2(g_1, g_2))}(U_{g_1} \circ U_{g_2}) \circ U_{g_3}. \quad (27)$$

Using the associativity of multiplication in the group U(1),

$$U_{g_1}(U_{g_2}U_{g_3}) = (U_{g_1}U_{g_2})U_{g_3},$$

we obtain

$$U_{g_1} \circ (U_{g_2} \circ U_{g_3}) = e^{i\alpha_3(g_1, g_2, g_3)}(U_{g_1} \circ U_{g_2}) \circ U_{g_3}, \quad (28)$$

where the 3-cocycle $\alpha_3(g_1, g_2, g_3)$ is given by

$$\alpha_3 = \alpha_2(g_2, g_3) - \alpha_2(g_1, g_2) + \alpha_2(g_1, g_3).$$

From the other hand, the product (28) can be written as

$$U_{g_1} \circ U_{g_2} = U_{g_1, g_2}, \quad (29)$$

where $g_1, g_2 = g_1 + g_2 + \alpha_2(g_1, g_2)$. Taking into account Eqs. (22), (24) and (26), we find that the triple-product satisfies

$$U_{g_1} \circ (U_{g_2} \circ U_{g_3}) = e^{i\Delta(g_1, g_2, g_3)}(U_{g_1} \circ U_{g_2}) \circ U_{g_3},$$

Comparing (27) and (29) we conclude that $\Delta(g_1, g_2, g_3) = \alpha_3(g_1, g_2, g_3)$, and thus, the associator is related to the 3-cocycle as follows:

$$l_{(g_1, g_2, g_3)} = g_3 + \alpha_3(g_1, g_2, g_3). \quad (30)$$

Since the loop QU(1) is isomorphic to the group U(1) if and only if the associator is identity map, one can see that this is equivalent to the vanishing of the 3-cocycle.

Assuming QU(1) to be a local loop, further being called the gauge loop, let us consider the wave function

$$\Psi(r) = e^{i\theta(r)}\psi(r), \quad e^{i\theta} \in QU(1), \quad (31)$$

and define the covariant derivative as

$$D_{\mu}\Psi = \left(\partial_{\mu} - ieA_{\mu}\right)\Psi \quad (32)$$

where $A_{\mu}$ is a “nonassociative” gauge field. Now applying (23) we find that the wave function $\Psi$ and gauge field $A$ transform as

$$U_{g_1} \Psi = e^{i\theta(g_1, g_2)}\Psi, \quad (33)$$

$$A' = A + \nabla\theta + \nabla\alpha_2(g_1, g_2). \quad (34)$$

It is easy to check that the curvature 2-form, $F = dA$, is invariant under the nonassociative gauge transformations.

Gauge loop in Dirac’s monopole problem. - Since the 3-cocycle $\alpha_3(r_1, r_2, r_3)$ emerges in the Dirac monopole problem as a general cocycle [17, 18], i.e. it depends on the point $r$ and the group elements, one has to extend the construction considered above. We generalize it in the following way: Let $Q$ be the local loop of maps $f_\gamma: \mathcal{M} \mapsto QU(1), \gamma \in \text{string}\mathcal{M}$. We define the extension $\text{string}\mathcal{M} \otimes Q$ with

$$\gamma_1(f_{\gamma_1})(f_{\gamma_2}) = (\gamma_1\gamma_2, f_{\gamma_1} \ast f_{\gamma_2}). \quad (35)$$
where the nonassociative product $f_{\gamma_1} * f_{\gamma_2}$ is specified as follows: Let $f_{\gamma}$ be the map

$$f_{\gamma} : r \mapsto U_{g_{\gamma}} = \exp \left( i \alpha_1 (r; \gamma) \right) \in \mathcal{Q},$$

then we define

$$U_{g_{\gamma_1}} * U_{g_{\gamma_2}} = U_{g_{\gamma_1 \cdot \gamma_2}} = e^{i \alpha_2 (r; \gamma_1, \gamma_2)} U_{g_{\gamma_1 \cdot \gamma_2}}, \quad (35)$$

$$g_{\gamma_1 \cdot \gamma_2} = \alpha_1 (r; \gamma_1) + \alpha_2 (r; \gamma_2) + \sigma(C, \Sigma), \quad (36)$$

where $r_1 = r_{\gamma_1}(1)$, and $\sigma(C, \Sigma)$ is the contribution of the Dirac string (see Eq. (15)). The 2-cochain $\alpha_2$ obeys the following commutation relations:

$$U_{g_{\gamma}} e^{i \alpha_2 (r; \gamma_1, \gamma_2)} = e^{i \alpha_2 (r'; \gamma_1, \gamma_2)} U_{g_{\gamma}}', \quad r' = r_{\gamma}(1). \quad (37)$$

For the triple-product we have the same result as has been obtained above (see Eq. (27)):

$$U_{g_{\gamma_1}} * (U_{g_{\gamma_2}} * U_{g_{\gamma_3}}) = e^{i \alpha_3 (r; \gamma_1, \gamma_2, \gamma_3)} (U_{g_{\gamma_1}} * U_{g_{\gamma_2}}) * U_{g_{\gamma_3}} \quad (38)$$

where $\alpha_3 = \pi \mu_3$ is the 3-cocycle.

Dirac’s ideas lead naturally to consideration of a quantum mechanics in which the wave function has a nonintegrable (or path-dependent) phase factor. This formalism has been developed by various authors (see, for example [22, 24, 26, 27, 28, 29, 30, 31] and references therein). In general, the path-dependent wave function can be written as

$$\Psi(r, \gamma) = e^{- i c \int f_{\gamma} A \cdot dr} \psi(r) \quad (39)$$

where the integration is performed along the path $\gamma$ joining the reference point $r_0$ with a point $r$, and $\psi(r)$ is a single-valued function.

Here, instead of taking the reference point for the construction of paths, we employ the group String $\mathcal{M}$ and introduce the path-dependent nonassociative wave function as

$$\Psi(r, \gamma) = e^{i \alpha_1 (r; \gamma)} \Psi(r), \quad \Psi(r, \gamma) \in \mathcal{Q}, \quad \gamma \in \text{String} \mathcal{M}. \quad (40)$$

The realization of the gauge loop $\mathcal{Q}$ in the space of the wave functions $\Psi(r, \gamma)$ is given by

$$U_{g_{\gamma}} * \Psi(r, \gamma) = e^{i \left( \alpha_1 (r; \gamma) + \sigma(C, \Sigma) \right)} \Psi(r, \gamma), \quad (41)$$

where $U_{g_{\gamma}} = \exp(i \alpha_1 (r; \gamma)) \in \mathcal{Q}$. Having nonassociative gauge transformations and wave functions, one can define the nonassociative vector potential as above (see Eqs. (31) - (33)).

IV. CONCLUDING REMARKS

Using of nonassociative structures is unavoidable when the Jacobi identity fails. The emerging difficulties associated with the contradictory nonassociative representations of the gauge group in the presence of the Dirac monopole may be removed by introducing nonassociative gauge transformations, which are related to the theory of quasigroups and loops. In quantum mechanical description of the monopole we deal with nonassociative path-dependent wave function $\Psi(r, \gamma)$, where $\gamma \in \text{String} \mathcal{M}$. Returning to the main subject, we see that nonassociative extension of the conventional group U(1) allows to avoid the Dirac quantization condition and obtain the consistent magnetic monopole theory with an arbitrary magnetic charge.

We close with some remarks about the relevance of this investigation to quantum mechanics and gauge field theory. Since a conventional quantum mechanics requires a linear Hilbert space and associative operators, the Dirac quantization rule is a necessary condition for the existence of quantum mechanics. Relaxation of this condition implies introducing of a nonassociative algebra of observables, and one must define an equivalent to quantum mechanics without Hilbert space. Non-vanishing 3-cocycles arising in quantum field theory force us to go beyond the standard approach and consider nonassociative generalization of the fibre bundle theory and related nonassociative gauge theories [32, 33]. This work is in progress.
