QUANTITATIVE REPRESENTATION STABILITY OVER LINEAR GROUPS

JEREMY MILLER AND JENNIFER C. H. WILSON

Abstract. We introduce a technique for proving quantitative representation stability theorems for sequences of representations of certain finite linear groups. We apply these techniques to the rational homology of congruence subgroups of mapping class groups and congruence subgroups of automorphism groups of free groups. This partially resolves a question raised by Church and Putman–Sam [PS14, Remark 1.8]. We also prove new homological stability results for mapping class groups and automorphism groups of free groups with twisted coefficients.

1. Introduction

Putman–Sam [PS14] introduced techniques for proving representation stability results in the sense of Church–Ellenberg–Farb [CEF15] for sequences of representations of several families of finite linear groups. They applied their tools to prove stability results for the homology groups of congruence...
subgroups of mapping class groups and automorphism groups of free groups. In this paper, we introduce new techniques that allow us to establish explicit stable ranges. Moreover, our methods do not require that we work with homology groups which are finitely generated. These stronger results come at the cost of working with field coefficients of characteristic zero.

1.1. Stability for congruence subgroups. The study of representation stability concerns the following framework: fix a sequence of groups with inclusions

$$G_0 \hookrightarrow G_1 \hookrightarrow G_2 \hookrightarrow G_3 \hookrightarrow \cdots$$

such as symmetric groups $S_n$, general linear groups $\text{GL}_n(k)$, or symplectic groups $\text{Sp}_{2n}(k)$. Fix a commutative ring $R$. Let $\{A_n\}$ be a sequence of $R[G_n]$–modules with the data of $G_n$–equivariant maps $A_n \to A_{n+1}$. The sequence $\{A_n\}$ is said to have generation degree $\leq d$ if, for all $n \geq d$, the $R[G_{n+1}]$–module generated by the image of $A_n$ is all of $A_{n+1}$. Informally, we say that the sequence $\{A_n\}$ stabilizes if its generation degree is finite. In this paper we also discuss a related notion called presentation degree.

The main examples of spaces that we consider are classifying spaces of congruence subgroups of mapping class groups and congruence subgroups of automorphism groups of free groups. Let $\text{Mod}(\Sigma_{g,r})$ denote the mapping class group of $\Sigma_{g,r}$, the compact orientable surface of genus $g$ with $r$ boundary components. The mapping class group acts on $H_1(\Sigma_{g,r})$. For $r \leq 1$, this action preserves the symplectic intersection form and so we get a map

$$\text{Mod}(\Sigma_{g,r}) \to \text{Sp}_{2g}(\mathbb{Z})$$

to the group $\text{Sp}_{2g}(\mathbb{Z})$ of symplectomorphisms of $\mathbb{Z}^{2g}$. Reducing modulo $p$ gives a map

$$\text{Mod}(\Sigma_{g,r}) \to \text{Sp}_{2g}(\mathbb{Z}/p\mathbb{Z})$$

and we denote the kernel by $\text{Mod}(\Sigma_{g,r}, p)$. This group is often called the level $p$ congruence subgroup of $\text{Mod}(\Sigma_{g,r})$. For $r = 0$, the classifying space of this group has the homotopy type of the moduli stack of smooth genus $g$ complex curves with full level $p$ structure. For $r \leq 1$, the homology groups $H_i(\text{Mod}(\Sigma_{g,r}, p); R)$ have the structure of a $R[\text{Sp}_{2g}(\mathbb{Z}/p\mathbb{Z})]$–module. For $r = 1$, the inclusions of surfaces $\Sigma_{g,1} \hookrightarrow \Sigma_{g+1,1}$ induce $\text{Sp}_{2g}(\mathbb{Z}/p\mathbb{Z})$–equivariant maps

$$H_i(\text{Mod}(\Sigma_{g,1}, p); R) \to H_i(\text{Mod}(\Sigma_{g+1,1}, p); R)$$

which allows us to make sense of stability. Our first result is the following.

**Theorem A.** Let $p \in \mathbb{Z}$ be a prime and $R$ a field of characteristic zero. The sequence $\{H_i(\text{Mod}(\Sigma_{g,1}, p); R)\}$ has generation degree $\leq$

$$\begin{cases} 
0 & \text{for } i = 0 \\
5 & \text{for } i = 1 \\
(8)3^{2i-3} & \text{for } i > 1.
\end{cases}$$

See Theorem 3.5 for a version of this theorem which addresses both generation and relation degree. Putman–Sam [PS14, Theorem K] proved that the degree of generation is finite when $R$ is any Noetherian ring, and Theorem A quantifies their result when $R$ is a field of characteristic zero.
A similar story is also true for automorphism groups of free groups. Let $F_n$ denote the free group on $n$ letters. The induced action of Aut($F_n$) on the abelianization $\mathbb{Z}^n$ of $F_n$ gives a surjective map

$$\text{Aut}(F_n) \rightarrow \text{GL}_n(\mathbb{Z}).$$

Reduction mod $p$ gives a surjective map

$$\text{Aut}(F_n) \rightarrow \text{GL}^{\pm}_n(\mathbb{Z}/p\mathbb{Z})$$

to the subgroup $\text{GL}^{\pm}_n(\mathbb{Z}/p\mathbb{Z}) \subseteq \text{GL}_n(\mathbb{Z}/p\mathbb{Z})$ of matrices with determinant $\pm 1$. We refer to the kernel of this map as the level $p$ congruence subgroup of Aut($F_n$) and denote it by Aut($F_n, p$). The standard inclusion $F_n \hookrightarrow F_{n+1}$ gives a $\text{GL}^{\pm}_n(\mathbb{Z}/p\mathbb{Z})$–equivariant map

$$H_i(\text{Aut}(F_n, p); R) \rightarrow H_i(\text{Aut}(F_{n+1}, p); R).$$

We prove the following theorem.

**Theorem B.** Let $p$ be a prime and $R$ a field of characteristic zero. The sequence $\{H_i(\text{Aut}(F_n, p); R)\}$ has generation degree $\leq \begin{cases} 0 & \text{for } i = 0 \\ 4 & \text{for } i = 1 \\ \left(\frac{15}{4}\right) \cdot 3^{2i-3} - \frac{i}{2} & \text{for } i > 1. \end{cases}$

See Theorem 3.7 for a version of this theorem which also addresses relation degree. As before, Putman–Sam [PS14, Theorem I] proved that the degree of generation is finite when $R$ is any Noetherian ring. In Remark 3.8, we discuss a generalization of Theorem B which applies to congruence subgroups of automorphism groups of free products of certain fundamental groups of 3-manifolds ($\mathbb{Z}$, $\mathbb{Z}/2$, $\mathbb{Z}/4$, $\mathbb{Z}/6$, $\pi_1(\Sigma_g)$ etc.). The techniques of Putman–Sam do not apply in this more general context as it is not currently known if the underlying vector spaces are finite dimensional.

### 1.2. Bounding higher syzygies.

To state our main technical tool and to state our homological stability with twisted coefficients theorems, we need the following categories first introduced by Putman–Sam.

We write $\text{Sl}(k)$ to denote the category whose objects are finite-rank free symplectic $k$–modules and whose morphisms are symplectic embeddings.

Given a category $C$ and a commutative ring $R$, the term $C$–module over $R$ will mean a functor from $C$ to the category of $R$–modules. We denote the category of $C$–modules over $R$ by $C$–Mod$_R$. Given a $C$–module $\mathcal{A}$ and an object $V$, let $\mathcal{A}_V$ denote the functor $\mathcal{A}$ evaluated on $V$. In the case $C = \text{Sl}(k)$, we write $\mathcal{A}_n$ to denote $\mathcal{A}_{k^{2n}}$, where we equip $k^{2n}$ with a standard symplectic form; see Section 2.1.

Since the automorphism group of $k^{2n}$ in $\text{Sl}(k)$ is $\text{Sp}_{2n}(k)$, the $R$–module $\mathcal{A}_n$ is naturally a $R[\text{Sp}_{2n}(k)]$–module. Symplectic inclusions $k^{2n} \hookrightarrow k^{2n+2}$ give $R[\text{Sp}_{2n}(k)]$–equivariant maps $\mathcal{A}_n \rightarrow \mathcal{A}_{n+1}$. Thus generation degree is well-defined for $\text{Sl}(k)$–modules. We will use these constructions to study the homology groups $H_i(\text{Mod}(\Sigma_{g,1}, p); R)$, which assemble to form an $\text{Sl}(\mathbb{Z}/p\mathbb{Z})$–module over $R$.

For $\mathcal{A}$ an $\text{Sl}(k)$–module, let

$$H^\text{Sl}_0: \text{Sl}(k)–\text{Mod}_R \rightarrow \text{Sl}(k)–\text{Mod}_R$$
be given by the formula
\[ H_0^{\text{SI}}(A)_V = \text{coker} \left( \bigoplus_{W \subseteq V} A_W \to A_V \right) \]
and let \( H_i^{\text{SI}} \) denote the \( i \)th left derived functor of \( H_0^{\text{SI}} \). Details are given in Section 2.4.

Vanishing of \( H_0^{\text{SI}}(M) \) controls the generation degree of \( M \) and vanishing of both \( H_0^{\text{SI}} \) and \( H_1^{\text{SI}} \) control the presentation degree of \( M \) (see Definition 2.9 and Proposition 2.35). Our main technical tool concerning \( \text{SI}(k) \)–modules is the following theorem.

**Theorem C.** Let \( k \) be a finite field and \( R \) a field of characteristic zero. Let \( A \) be an \( \text{SI}(k) \)–module over \( R \) with \( H_0^{\text{SI}}(A)_n = 0 \) for \( n > d \) and \( H_1^{\text{SI}}(A)_n = 0 \) for \( n > r \). Then for \( i \geq 2 \) the group \( H_i^{\text{SI}}(A)_n \) vanishes for \( n > 3^{i-1} \max(r, d) \).

The above theorem is analogous to the regularity theorem of Church–Ellenberg [CE17, Theorem A] for \( \text{FI} \)–modules, although our techniques are different. This theorem shows that we can bound the generation degrees of modules of higher syzygies in terms of the degrees of generators and relations. It serves the same purpose in this paper that the Noetherian theorems serve in Putman–Sam [PS14].

For \( U \) a subgroup of the group of units of \( k \), let \( \text{GL}_n^U(k) \) denote the subgroup of matrices with determinant in \( U \). Putman–Sam [PS14] introduced a category \( \text{VIC}^U(k) \) whose automorphism groups are \( \text{GL}_n^U(k) \), defined in Definition 2.2. The groups \( H_i(\text{Aut}(F_n, p)) \) assemble to form a \( \text{VIC}^U(Z/pZ) \)–module. We prove the following result concerning syzygies of \( \text{VIC}^U(k) \)–modules.

**Theorem D.** Let \( k \) be a finite field and \( R \) a field of characteristic zero. Let \( A \) be a \( \text{VIC}^U(k) \)–module over \( R \) with \( H_0^{\text{VIC}^U}(A)_n = 0 \) for \( n > d \) and \( H_1^{\text{VIC}^U}(A)_n = 0 \) for \( n > r \). Then for \( i \geq 2 \) the group \( H_i^{\text{VIC}^U}(A)_n \) vanishes for \( n > 3^{i-1} \left( \max(r, d) + \frac{1}{2} \right) - \frac{1}{2} \).

These theorems imply that when \( k \) is a finite field and \( R \) is a field of characteristic zero, the categories of \( \text{SI}(k) \)– and \( \text{VIC}^U(k) \)–modules with finite presentation degree are abelian categories; see Corollary 2.36.

### 1.3. Homological stability with twisted coefficients.

Our techniques can also be applied to prove homological stability theorems with twisted coefficients.

**Theorem E.** Let \( p \in Z \) be prime. Let \( R \) be a field of characteristic zero and let \( A \) be an \( \text{SI}(Z/pZ) \)–module over \( R \) with generation degree \( \leq d \) and relation degree \( \leq r \). Then an inclusion \( \Sigma_{g,1} \hookrightarrow \Sigma_{g+1,1} \) induces an isomorphism
\[
H_i(\text{Mod}(\Sigma_{g,1}); A_g) \to H_i(\text{Mod}(\Sigma_{g+1,1}); A_{g+1})
\]
whenever \( g \geq \begin{cases} \max(d, r) & \text{for } i = 0 \\ \max(8 + d, 5 + r) & \text{for } i = 1 \\ \max((8)3^{2i-2} + d, (8)3^{2i-3} + r) & \text{for } i > 1. \end{cases} \)

Similarly, we prove the following stability theorem for automorphism groups of free groups.
Theorem F. Let $p \in \mathbb{Z}$ be prime. Let $R$ be a field of characteristic zero and let $A$ be a $\text{VIC}^\pm(\mathbb{Z}/p\mathbb{Z})$–module over $R$ with generation degree $\leq d$ and relation degree $\leq r$. Then the inclusion $F_n \hookrightarrow F_{n+1}$ induces an isomorphism

$$H_i(\text{Aut}(F_n); A_n) \rightarrow H_i(\text{Aut}(F_{n+1}); A_{n+1})$$

whenever $n \geq \max(d, r)$ for $i = 0$,

$\max(6 + d, 4 + r)$ for $i = 1$,

$\max((\frac{13}{2})3^{2i-2} - \frac{1}{2} + d, (\frac{13}{2})3^{2i-3} - \frac{1}{2} + r)$ for $i > 1$.

These twisted stability theorems are qualitatively different than stability theorems with polynomial coefficients, for example, the coefficients considered in [RWW17]. See the discussion before Theorem L in [PS14] or Example 1.4 of [MPW17] for an exposition of this difference. In fact, the work of Gan–Watterlond [GW16] implies that there are no non-constant polynomial coefficient systems in our context.

1.4. Outline. In Section 2, we construct bounded resolutions of $\text{Sl}(\mathbb{k})$ and $\text{VIC}^U(\mathbb{k})$–modules. We use these resolutions in Section 3 where we prove representation stability for congruence subgroups of mapping class groups and automorphism groups of free groups. We use these representation stability results in Section 4 to prove twisted homological stability theorems for mapping class groups and automorphism groups of free groups.

1.5. Acknowledgments. We would like to thank Daniel Bump, Thomas Church, Benson Farb, Rohit Nagpal, Peter Patzt, Andrew Putman, and Eric Ramos for helpful conversations.

2. Algebraic results

In this section, we bound the generation degrees of the modules of higher syzygies of $\text{Sl}(\mathbb{k})$ and $\text{VIC}^U(\mathbb{k})$–modules over $R$ that have finite presentation degree. Our main theorems require that $R$ be a field of characteristic zero and that $\mathbb{k}$ be a finite field. However, many of our intermediate results apply in more generality.

2.1. $C$–modules. We begin by defining the categories of interest. All rings are assumed to have unit.

Definition 2.1. Let $R$ and $\mathbb{k}$ be commutative rings. Let $\text{VIC}(\mathbb{k})$ be the category whose objects are finite-rank free $\mathbb{k}$–modules, and whose morphisms $U \rightarrow V$ are defined to be the set

$$\text{Hom}_{\text{VIC}}(U, V) = \left\{ f = (T, C) \mid T: U \rightarrow V \text{ an injective linear map,} \right. C \text{ a specified direct complement of } T(U) \text{ in } V. \right\}$$

Composition of morphisms is defined by the rule

$$(T, C) \circ (S, D) = (T \circ S, C \oplus f(D)).$$

Similarly $\text{Sl}(\mathbb{k})$ denotes the category of finite-rank free symplectic $\mathbb{k}$–modules and injective, isometric embeddings.

We note that the image of a symplectic embedding $f : V \rightarrow W$ has a unique symplectic complement $f(V)^\perp \subset W$.

We will use the following generalization of $\text{VIC}$, defined by Putman–Sam [PS14, Section 1.2].
Definition 2.2. Fix a commutative ring \( \mathbf{k} \) and a subgroup \( U \subseteq \mathbf{k}^\times \). Let

\[
\text{GL}^U_\mathbf{k}(k) = \{ A \in \text{GL}_n(k) \mid \det A \in U \}.
\]

We write \( \text{VIC}^U(\mathbf{k}) \) to denote the following category. Its objects are finite-rank free \( \mathbf{k} \)-modules \( V \) such that nonzero objects are assigned a \( U \)-orientation, a generator of

\[
\bigwedge^{\text{rank}_\mathbf{k}(V)} V \cong \mathbf{k}
\]

defined up to multiplication by \( U \). If \( V \) and \( W \) have the same rank, then \( \text{Hom}_{\text{VIC}^U(\mathbf{k})}(V, W) \) is the set of linear isomorphisms that respect the designated \( U \)-orientations. If \( V \) has strictly smaller rank than \( W \), then a morphism \( V \to W \) is a complemented injective linear map \( f = (T, C) \), for which we assign to \( C \) the unique \( U \)-orientation such that

\[
T(V) \oplus C \cong W
\]

as oriented \( \mathbf{k} \)-modules.

Here \( T(V) \) is equipped with the orientation induced by the \( U \)-orientation on \( V \).

In particular,

\[
\text{End}_{\text{VIC}^U(\mathbf{k})}(k^n) \cong \text{GL}^U_n(\mathbf{k}),
\]

but if \( V \) has strictly smaller rank than \( W \), then

\[
\text{Hom}_{\text{VIC}^U(\mathbf{k})}(V, W) \cong \text{Hom}_{\text{VIC}(\mathbf{k})}(V, W).
\]

When \( U = \{1, -1\} \), we write \( \text{VIC}^U(\mathbf{k}) \) for \( \text{VIC}^U(k) \). Note that when \( U = \mathbf{k}^\times \), the category \( \text{VIC}^U \) is isomorphic to \( \text{VIC} \).

For convenience, we will often work with a skeleton of the category \( \text{VIC}(\mathbf{k}) \) or \( \text{VIC}^U(\mathbf{k}) \), the full subcategory with objects \( \mathbf{k}^d, d \geq 0 \). Given these choices of bases for our objects, when convenient we can represent our morphisms \( (T, C) : \mathbf{k}^d \to \mathbf{k}^n \) by an equivalence class of \((n \times n)\) matrices in \( \text{GL}^U_n(\mathbf{k}) \) where the first \( d \) columns are the matrix representative for \( T \), and the final \( n - d \) columns span \( C \).

Similarly, we may choose a skeleton of \( \text{SL}(\mathbf{k}) \) of symplectic vector spaces \( \mathbf{k}^{2d} \) with symplectic form

\[
\Omega_d = \begin{bmatrix}
0 & 1 \\
-1 & 0 \\
\vdots & \ddots \\
0 & 0 & 1 \\
-1 & 0
\end{bmatrix}.
\]

A morphism \( \mathbf{k}^{2d} \to \mathbf{k}^{2n} \) is given by a \((2n \times 2d)\) matrix \( A \) that satisfies \( A^T \Omega_n A = \Omega_d \).

Remark 2.3. Consider the action of \( \text{End}_{\text{VIC}^U(\mathbf{k})}(k^n) \cong \text{GL}^U_n(\mathbf{k}) \) on the morphisms \( \text{Hom}_{\text{VIC}^U(\mathbf{k})}(\mathbf{k}^d, \mathbf{k}^n) \). A morphism \( f = (T, C) \) has stabilizer \( \text{GL}^U_n(C) \cong \text{GL}^U_{n-d}(\mathbf{k}) \) in \( \text{GL}^U_n(\mathbf{k}) \). Similarly, a morphism \( f \in \text{Hom}_{\text{SL}(\mathbf{k})}(\mathbf{k}^{2d}, \mathbf{k}^{2n}) \) has stabilizer \( \text{Sp}(f(\mathbf{k}^{2d})) \cong \text{Sp}_{2n-2d}(\mathbf{k}) \) in \( \text{Sp}_{2n}(\mathbf{k}) \), where again \( f(\mathbf{k}^{2d}) \) denotes the symplectic complement of \( f(\mathbf{k}^{2d}) \subseteq \mathbf{k}^{2n} \).

Throughout the paper we will let \( \mathcal{C} \) generically refer to the category \( \text{SL}(\mathbf{k}) \) or \( \text{VIC}^U(\mathbf{k}) \), and denote the endomorphisms \( \text{End}_{\text{VIC}^U(\mathbf{k})}(k^n) \cong \text{GL}^U_n(\mathbf{k}) \) or \( \text{End}_{\text{SL}(\mathbf{k})}(k^{2n}) \cong \text{Sp}_{2n}(\mathbf{k}) \) generically by \( G_n \). We stress that for the category \( \text{SL}(\mathbf{k}) \), these indices \( n \) are half the rank of the corresponding symplectic \( \mathbf{k} \)-module \( \mathbf{k}^{2n} \).
Definition 2.4. We write \( \mathbf{CB} \) to denote the subcategory of \( \mathcal{C} \) with the same objects as \( \mathcal{C} \), whose morphisms are all isomorphisms of \( \mathcal{C} \). A \( \mathbf{CB} \)-module \( W \) is therefore a sequence \( W = \{ W_n \} \) of \( G_n \)-representations, and we define the support of a \( \mathbf{CB} \)-module to be the set \( \{ n \in \mathbb{Z}_{\geq 0} \mid W_n \neq 0 \} \).

Definition 2.5. Let \( \mathcal{M}(d) \) denote the representable \( \mathcal{VIC}^U(\mathbb{k}) \)-module
\[
\mathbb{k}^n \mapsto R[\text{Hom}_{\mathcal{VIC}^U(\mathbb{k})}(\mathbb{k}^d, \mathbb{k}^n)]
\]
or the representable \( \mathcal{SI}(\mathbb{k}) \)-module
\[
\mathbb{k}^{2n} \mapsto R[\text{Hom}_{\mathcal{SI}(\mathbb{k})}(\mathbb{k}^{2d}, \mathbb{k}^{2n})].
\]
In both cases such a morphism has stabilizer \( G_{n-d} \) by Remark 2.3, and so there are isomorphisms of \( G_n \)-representations
\[
\mathcal{M}(d)_n \cong R[G_n/G_{n-d}] \cong \text{Ind}_{G_{n-d}}^{G_n} R \cong \text{Ind}_{G_d \times G_{n-d}}^{G_n} R[G_d] \boxtimes R
\]
where \( R \) denotes the trivial \( G_{n-d} \)-representation.

We sometimes write \( \mathcal{M}^{\mathcal{VIC}}(d) \), \( \mathcal{M}^{\mathcal{VIC}^U}(d) \), or \( \mathcal{M}^{\mathcal{SI}}(d) \) for \( \mathcal{M}(d) \) when we wish to specialize to a particular category \( \mathcal{C} = \mathcal{VIC}(\mathbb{k}) \), \( \mathcal{C} = \mathcal{VIC}^U(\mathbb{k}) \), or \( \mathcal{C} = \mathcal{SI}(\mathbb{k}) \).

Definition 2.6. We define the functor
\[
\mathcal{M} : \mathbf{CB} \text{-Mod} \rightarrow \mathcal{C} \text{-Mod}
\]
to be the left adjoint to the forgetful functor
\[
\mathcal{F} : \mathcal{C} \text{-Mod} \rightarrow \mathbf{CB} \text{-Mod}
\]
\[
\mathcal{A} \mapsto \{ \mathcal{A}_n \}
\]
Concretely, given a \( G_d \)-representation \( W \) (viewed as a \( \mathbf{CB} \)-module supported in degree \( d \)), the \( \mathcal{C} \)-module \( \mathcal{M}(W) \) satisfies
\[
\mathcal{M}(W) = \mathcal{M}(d) \otimes_{R[G_d]} W.
\]
As a \( G_n \)-representation,
\[
\mathcal{M}(W)_n \cong \begin{cases} 
0 & n < d \\
\text{Ind}_{G_d \times G_{n-d}}^{G_n} W \boxtimes R & n \geq d.
\end{cases}
\]
Given a general \( \mathbf{CB} \)-module \( W = \{ W_n \} \), the \( \mathcal{C} \)-module \( \mathcal{M}(W) \) is given by the formula
\[
\mathcal{M} : \mathbf{CB} \text{-Mod} \rightarrow \mathcal{C} \text{-Mod}
\]
\[
\{ W_n \} \mapsto \bigoplus_{m \geq 0} \mathcal{M}(W_m)
\]
These formulas follow as in Church–Ellenberg–Farb [CEF15, Definition 2.2.2 and Equation (4)]. Following the terminology of Nagpal–Sam–Snowden [NSS17], we call \( \mathcal{C} \)-modules of this form induced \( \mathcal{C} \)-modules. Again we sometimes write \( \mathcal{M}^{\mathcal{VIC}}(W) \), \( \mathcal{M}^{\mathcal{VIC}^U}(W) \), or \( \mathcal{M}^{\mathcal{SI}}(W) \) for \( \mathcal{M}(W) \) when \( \mathcal{C} = \mathcal{VIC}(\mathbb{k}) \), \( \mathcal{VIC}^U(\mathbb{k}) \), or \( \mathcal{SI}(\mathbb{k}) \).

Proposition 2.7. For any projective \( \mathbf{CB} \)-module \( W \), the \( \mathcal{C} \)-module \( \mathcal{M}(W) \) is projective. In particular, if \( \mathbb{k} \) is a finite commutative ring and \( R \) a field of characteristic zero, then \( \mathcal{M}(W) \) is projective for all \( \mathbf{CB} \)-modules \( W \).
Proof. Since \( \mathcal{M} \) is the left adjoint of the exact forgetful functor, it preserves projectives; see Weibel [Wei95, Proposition 2.3.10]. When the algebras \( R[G_n] \) are semi-simple then all \( \mathbf{C} \mathbf{B} \)-modules are projective. □

From the formula for \( \mathcal{M}(W) \), and because induction of group representations is an exact operation, we deduce the following.

**Proposition 2.8.** The functor \( \mathcal{M} : \mathbf{C} \mathbf{B} \text{-Mod} \to \mathcal{C} \text{-Mod} \) is exact.

We now introduce the concepts of generation, relation, and presentation degree.

**Definition 2.9.** A \( \mathcal{C} \)-module \( \mathcal{A} \) is generated in degree \( \leq d \) if \( \mathcal{A} \) can be expressed as a quotient of a \( \mathcal{C} \)-module of the form \( \mathcal{M}(W) \to \mathcal{A} \) for some \( \mathbf{C} \mathbf{B} \)-module \( W \) supported in degrees \( \leq d \). We say that \( \mathcal{A} \) is related in degree \( \leq r \) if \( \mathcal{A} \) can be expressed as a quotient as above whose kernel is generated in degree \( \leq r \). If \( \mathcal{A} \) is generated in degree \( \leq d \) and related in degree \( \leq r \), we say it has presentation degree \( \leq \max(d, r) \).

**Proposition 2.10.** Let \( \mathcal{A} \) be a \( \mathcal{C} \)-module. The following statements are all equivalent to the condition that \( \mathcal{A} \) is generated in degree \( \leq d \).

(a) \( \mathcal{A} \) is a quotient of an induced \( \mathcal{C} \)-module \( \mathcal{M}(W) \to \mathcal{A} \) with \( W \) supported in degrees \( \leq d \).

(b) For all \( n \geq d \), the \( G_{n+1} \)-representation \( \mathcal{A}_{n+1} \) is generated by the image of \( \mathcal{A}_n \) in \( \mathcal{A}_{n+1} \) under any map induced by a \( \mathcal{C} \)-morphism.

(c) For all \( n \geq d \), the \( \mathcal{C} \) morphisms induce surjections \( \text{Ind}_{G_{n+1}}^{G_n} \mathcal{A}_n \to \mathcal{A}_{n+1} \).

(d) The subset \( \{ \mathcal{A}_n \}_{n=0}^{d} \) of \( \mathcal{A} \) is not contained in any proper \( \mathcal{C} \)-submodule of \( \mathcal{A} \).

(e) The inclusion of \( \mathbf{C} \mathbf{B} \)-modules \( \{ \mathcal{A}_n \}_{n=0}^{d} \to \{ \mathcal{A}_n \} \) induces a surjective map of \( \mathcal{C} \)-modules \( \mathcal{M}(\{ \mathcal{A}_n \}_{n=0}^{d}) \to \mathcal{A} \).

Proof. We can verify directly that if \( W \) is supported in degrees \( \leq d \) then \( \mathcal{M}(W) \) satisfies (b), and hence its \( \mathcal{C} \)-module quotients do. Thus (a) implies (b). Parts (b) and (c) are equivalent by definition of induction. It is straightforward to conclude (d) from (b). Part (d) implies that any map of \( \mathcal{C} \)-modules to \( \mathcal{A} \) that is surjective in the first \( d \) degrees must surject in all degrees, and so implies (e). Part (a) is immediate from part (e). □

**Remark 2.11.** We note that the induced \( \mathcal{C} \)-module \( \mathcal{M}(W) \) is generated in degree \( \leq d \) if and only if \( W \) is supported in degree \( \leq d \).

**Proposition 2.12.** Let \( k \) be a finite field and let \( R \) be a field of characteristic zero. Any induced \( \mathcal{C} \)-module \( \mathcal{M}(W) \) can be realized as both a \( \mathcal{C} \)-module quotient, and a \( \mathcal{C} \)-submodule, of \( \mathcal{C} \)-modules of the form

\[
\bigoplus_{m=0}^{\infty} \mathcal{M}(m)^{\oplus c_m}
\]

for some (possibly infinite) multiplicities \( c_m \). If \( \mathcal{M}(W) \) is generated in degree \( \leq d \), then we can realize it as a quotient or a submodule of \( \mathcal{C} \)-modules of the form

\[
\bigoplus_{m=0}^{d} \mathcal{M}(m)^{\oplus c_m}.
\]
More generally, if \( A \) is any \( \mathbb{C} \)–module generated in degree \( \leq d \), then we can realize \( A \) as a quotient of a \( \mathbb{C} \)–module of the form
\[
\bigoplus_{m=0}^{d} M(m)^{\oplus c_m}.
\]

Notably, the following constructions are valid even if we allow the \( R[G_n] \)–representations \( W_n \) to be infinite-dimensional.

**Proof of Proposition 2.12.** Observe that we can construct a \( \mathbb{CB} \)–module \( \{R[G_m]^{\oplus c_m}\} \) so as to obtain a map of \( \mathbb{CB} \)–modules
\[
R[G_n]^{\oplus c_n} \to W_n
\]
that surjects in each degree \( n \). If \( W \) is supported in degree \( \leq d \) we may take \( c_n = 0 \) for \( n > d \). Applying the functor \( \mathcal{M} \) we obtain a map of \( \mathbb{C} \)–modules,
\[
\mathcal{M} \left( \{R[G_m]^{\oplus c_m}\} \right) = \bigoplus_{m} \mathcal{M} (m)^{\oplus c_m} \to \mathcal{M}(W),
\]
and by Proposition 2.8 this map surjects.

Moreover, since the algebras \( R[G_n] \) are semi-simple by assumption, the maps \( R[G_n]^{\oplus c_n} \to W_n \) split to give an injective map of \( \mathbb{CB} \)–modules \( W \to \{R[G_n]^{\oplus c_n}\} \). Again the induced map
\[
\mathcal{M}(W) \to \bigoplus_{m} \mathcal{M} (m)^{\oplus c_m}
\]
is injective by Proposition 2.8.

Finally, if \( A \) is any \( \mathbb{C} \)–module generated in degree \( \leq d \), then by definition of generation degree we can realize \( A \) as a quotient \( \mathcal{M}(W) \to A \) with \( W \) supported in degree \( \leq d \). Then we may compose this map with the surjection constructed above to obtain the desired surjective map
\[
\bigoplus_{m=0}^{d} \mathcal{M} (m)^{\oplus c_m} \to \mathcal{M}(W) \to A.
\]

\( \square \)

**2.2. Weight and stability degree.** In this subsection, we will introduce concepts of weight and stability degree for \( \mathbb{C} \)–modules, closely analogous to the concepts of the same name used by Church, Ellenberg, and Farb \([CEF15]\) in the study of \( \mathbb{FI} \)–modules. These \( \mathbb{C} \)–module invariants will be our main tool for bounding the generation degrees of the terms in resolutions of \( \mathbb{C} \)–modules.

**Definition 2.13.** A \( \mathbb{C} \)–module \( A \) has weight \( \leq d \) if for each \( n \), the \( G_n \)–representation \( A_n \) is a subquotient of a representation of the form \( \bigoplus_{m \leq d} \mathcal{M}(m)^{\oplus c_m} \) for some (possibly infinite) coefficients \( c_m \).

**Remark 2.14.** It follows from the definition that if \( A \) is a \( \mathbb{C} \)–module of weight \( \leq d \), then any subquotient of \( A \) has weight \( \leq d \).

**Remark 2.15.** By Proposition 2.12, any \( \mathbb{C} \)–module \( A \) generated in degree \( \leq d \) must be a quotient of the form in Definition 2.13, and so \( A \) has weight \( \leq d \).

**Lemma 2.16.** Let \( k \) be a finite commutative ring, and let \( R \) be a field of characteristic zero. Suppose that \( A \) is a \( \mathbb{C} \)–module over \( R \) of weight \( \leq d \), and that \( C_n \) is any subquotient of the \( G_n \)–representation \( A_n \). Then \( C_n = 0 \) if and only if \( (C_n)_{G_{n-d}} = 0 \).
An analogous statement for FI-modules was proved by Church–Ellenberg–Farb [CEF15, Lemma 3.2.7(iv)]. Their proof uses combinatorial properties of the branching rules for induction of symmetric group representations. The following proof instead uses Frobenius reciprocity.

Proof of Lemma 2.16. If \( C_n = 0 \), then its coinvariants must vanish. So suppose that \( (C_n)_{G_n} = 0 \). Note that if \( m \leq d \), then \( (C_n)_{G_n - m} \) is a quotient of \( (C_n)_{G_n - d} \) and therefore also vanishes. To verify that \( C_n \) vanishes, it is enough to show that

\[
\text{Hom}_{R[G_n]}(U, C_n) = 0 \quad \text{for all } G_n\text{-representations } U.
\]

By the definition of weight, and because we are working with finite groups over characteristic zero, any irreducible subrepresentation of \( C_n \) must be contained in a \( G_n \)-representation \( U \) of the form

\[
U = \text{Ind}_{G_m \times G_n - m}^{G_n} R[G_m] \boxtimes R \quad \text{with } m \leq d
\]

so it suffices to check that \( \text{Hom}_{R[G_n]}(U, C_n) = 0 \) in this case. Using Frobenius reciprocity (or the tensor-Hom adjunction), we find

\[
\text{Hom}_{R[G_n]} \left( \text{Ind}_{G_m \times G_n - m}^{G_n} R[G_m] \boxtimes R, C_n \right)
\]

\[
= \text{Hom}_{R[G_m \times G_n - m]} \left( R[G_m] \boxtimes R, \text{Res}_{G_m \times G_n - m}^{G_n} C_n \right)
\]

\[
= \text{Hom}_{R[G_m]} \left( R[G_m], (C_n)_{G_n - m} \right)
\]

\[
= 0
\]

as claimed. \( \square \)

Definition 2.17. A \( C \)-module \( A \) has stability degree \( \leq s \) if for each \( a \geq 0 \), the induced map

\[
(A_n)_{G_n - a} \longrightarrow (A_{n+1})_{G_{n+1} - a}
\]

is an isomorphism for all \( n \geq s + a \). We further say that \( A \) has injectivity degree \( \leq s \) if these maps are injective for \( n \geq s + a \), and surjectivity degree \( \leq s \) if these maps are surjective for \( n \geq s + a \). We use the notation \( \text{InjDeg}(A) \leq s \) (respectively, \( \text{SurjDeg}(A) \leq s \)) to indicate that \( A \) has injectivity degree (respectively, surjectivity degree) \( \leq s \).

Proposition 2.18. Let \( k \) be a finite commutative ring, let \( R \) be a field of characteristic zero, and let \( B \) be a \( C \)-module over \( R \). If \( B \) has surjectivity degree \( \leq s \), then so does any quotient of \( B \). If \( B \) has injectivity degree \( \leq t \), then so does any submodule of \( B \).

Proof. Suppose that \( A \) is a submodule of \( B \) and that \( C \) is a quotient. Since the operation of taking coinvariants by a finite group is exact over characteristic zero, we obtain the following commutative diagrams. For \( n \geq a + t \), the diagram

\[
\begin{array}{ccc}
(A_n)_{G_n - a} & \longrightarrow & (A_{n+1})_{G_{n+1} - a} \\
\downarrow & & \downarrow \\
(B_n)_{G_n - a} & \longrightarrow & (B_{n+1})_{G_{n+1} - a}
\end{array}
\]
implies that the map \((A_n)_{G_{n-a}} \rightarrow (A_{n+1})_{G_{n+1-a}}\) injects.

For \(n \geq a + s\), the diagram

\[
\begin{array}{ccc}
(B_n)_{G_{n-a}} & \rightarrow & (B_{n+1})_{G_{n+1-a}} \\
\downarrow & & \downarrow \\
(C_n)_{G_{n-a}} & \rightarrow & (C_{n+1})_{G_{n+1-a}}
\end{array}
\]

shows that the map \((C_n)_{G_{n-a}} \rightarrow (C_{n+1})_{G_{n+1-a}}\) is surjective. \(\square\)

**Proposition 2.19.** Let \(k\) be a finite commutative ring, let \(R\) be a field of characteristic zero, and let \(f : A \rightarrow B\) be a map of \(C\)-modules over \(R\). Then

\[
\begin{align*}
\text{InjDeg}(\ker f) & \leq \text{InjDeg}(A) \\
\text{SurjDeg}(\ker f) & \leq \max \left( \text{SurjDeg}(A), \text{InjDeg}(B) \right) \\
\text{InjDeg}(\coker f) & \leq \max \left( \text{SurjDeg}(A), \text{InjDeg}(B) \right) \\
\text{SurjDeg}(\coker f) & \leq \text{SurjDeg}(B).
\end{align*}
\]

**Proof.** The results \(\text{InjDeg}(\ker f) \leq \text{InjDeg}(A)\) and \(\text{SurjDeg}(\coker f) \leq \text{SurjDeg}(B)\) follow from Proposition 2.18.

Since taking coinvariants is exact over \(R\), for \(n \geq a + \max \left( \text{SurjDeg}(A), \text{InjDeg}(B) \right)\) we obtain the following commutative diagram with exact columns

\[
\begin{array}{ccc}
(ker f_n)_{G_{n-a}} & \rightarrow & (ker f_{n+1})_{G_{n+1-a}} \\
\downarrow & & \downarrow \\
(A_n)_{G_{n-a}} & \rightarrow & (A_{n+1})_{G_{n+1-a}} \\
\downarrow f_* & & \downarrow f_* \\
(B_n)_{G_{n-a}} & \rightarrow & (B_{n+1})_{G_{n+1-a}}
\end{array}
\]

A routine diagram chase demonstrates that the map \((ker f_n)_{G_{n-a}} \rightarrow (ker f_{n+1})_{G_{n+1-a}}\) surjects, as desired. We also obtain, for \(n \geq a + \max \left( \text{SurjDeg}(A), \text{InjDeg}(B) \right)\) the commutative diagram with exact columns

\[
\begin{array}{ccc}
(A_n)_{G_{n-a}} & \rightarrow & (A_{n+1})_{G_{n+1-a}} \\
\downarrow f_* & & \downarrow f_* \\
(B_n)_{G_{n-a}} & \rightarrow & (B_{n+1})_{G_{n+1-a}} \\
\downarrow & & \downarrow \\
(coker f_n)_{G_{n-a}} & \rightarrow & (coker f_{n+1})_{G_{n+1-a}}
\end{array}
\]

We can verify that the kernel of the map \((coker f_n)_{G_{n-a}} \rightarrow (coker f_{n+1})_{G_{n+1-a}}\) vanishes, which concludes the proof. \(\square\)
Patzt proved the following result on the stability degree of representable $\mathbb{C}$–modules. We remark that, although he only states the results for $\mathbb{k} = \mathbb{Q}$, his proof only uses the assumption that $\mathbb{k}$ is a field.

**Proposition 2.20** (Patzt [Pat16, Proposition 3.11]). Let $R$ be ring and $\mathbb{k}$ a field. Let $\mathbb{C}$ be the category $\text{VIC}(\mathbb{k})$ or $\text{Sl}(\mathbb{k})$. Then the represented $\mathbb{C}$–module $\mathcal{M}(d)$ over $R$ has injectivity degree $\leq 0$, and surjectivity degree $\leq 2d$.

We now explain how to leverage this result to prove an analogous statement for $\text{VIC}^U(\mathbb{k})$.

**Proposition 2.21.** Let $R$ be ring, $\mathbb{k}$ a field, and $U$ a subgroup of $\mathbb{k}^\times$. Then the represented $\text{VIC}^U(\mathbb{k})$–module $\mathcal{M}(d)$ over $R$ has injectivity degree $\leq 2d + 1$, and surjectivity degree $\leq 2d$.

*Proof.* Fix $a \geq 0$. Let $I_m$ denote the $(m \times m)$ identity matrix. By definition the $\text{GL}^U_n(\mathbb{k})$–representation $\mathcal{M}(d)_n$ is a permutation representation with $R$–basis the set of cosets $\text{GL}^U_n(\mathbb{k})/\text{GL}^U_{n-d}(\mathbb{k})$. It follows that its coinvariants $(\mathcal{M}(d)_n)_{\text{GL}^U_{n-d}(\mathbb{k})}$ has $R$–basis the set of double cosets

$$\text{GL}^U_{n-d}(\mathbb{k}) \backslash \text{GL}^U_n(\mathbb{k})/\text{GL}^U_{n-d}(\mathbb{k}).$$

Concretely, this is the set of $(n \times n)$ matrices $B$ with determinants in $U$ defined up the action of

$$\text{GL}^U_{n-a}(\mathbb{k}) \cong \left\{ \begin{pmatrix} I_a & 0 \\ 0 & * \end{pmatrix} \right\}$$

on the left – acting by row operations on the bottom $(n-a)$ rows of $B$ – and the action of

$$\text{GL}^U_{n-d}(\mathbb{k}) \cong \left\{ \begin{pmatrix} I_d & 0 \\ 0 & * \end{pmatrix} \right\}$$

on the right, acting by column operations on the rightmost $(n-d)$ columns of $B$. The map

$$(\mathcal{M}(d)_n)_{\text{GL}^U_{n-d}(\mathbb{k})} \rightarrow (\mathcal{M}(d)_{n+1})_{\text{GL}^U_{n+1-d}(\mathbb{k})}$$

defining stability degree is induced by the map

$$\text{GL}^U_n(\mathbb{k}) \rightarrow \text{GL}^U_{n+1}(\mathbb{k})$$

$$C \mapsto \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix}.$$

We will first establish the bound on surjectivity degree for $\mathcal{M}(d)$, by proving that the map

$$\text{GL}^U_{n-a}(\mathbb{k}) \backslash \text{GL}^U_n(\mathbb{k})/\text{GL}^U_{n-d}(\mathbb{k}) \rightarrow \text{GL}^U_{n+1-a}(\mathbb{k}) \backslash \text{GL}^U_{n+1}(\mathbb{k})/\text{GL}^U_{n+1-d}(\mathbb{k})$$
surjects for $n \geq 2d + a$. When $d = 0$, the domain and codomain are both singleton sets and the result is immediate, so we may assume $d > 0$. Let $B$ be any matrix in $\text{GL}^U_{n+1}(\mathbb{k})$. Patzt proved that $\mathcal{M}^\text{VIC}(d)$
has surjectivity degree \( \leq 2d \); specifically, he found matrices \( A \in \text{GL}_{n+1-a}(k) \), \( D \in \text{GL}_{n+1-d}(k) \), and \( C \in \text{GL}_n(k) \) so that

\[
\begin{bmatrix}
I_n & A \\
0 & D \\
\end{bmatrix} B 
\begin{bmatrix}
I_d & D \\
0 & D \\
\end{bmatrix} = 
\begin{bmatrix}
0 & 0 \\
C & \vdots \\
0 & 0 \\
\end{bmatrix}.
\]

Our goal is to modify \( A, D, \) and \( C \) so that they have determinants in \( U \). Observe that

\[
\left( 
\begin{bmatrix}
1 & \cdots & 1 \\
& \vdots & \ddots \\
& & 1 \\
\end{bmatrix} 
\begin{bmatrix}
I_n & A \\
0 & D \\
\end{bmatrix} 
\right) 
B 
\left( 
\begin{bmatrix}
I_d & D \\
0 & D \\
\end{bmatrix} 
\right) 
= 
\left( 
\begin{bmatrix}
1 & \cdots & 1 \\
& \vdots & \ddots \\
& & 1 \\
\end{bmatrix} 
\begin{bmatrix}
I_n & A \\
0 & D \\
\end{bmatrix} 
\right) 
B 
\left( 
\begin{bmatrix}
I_d & D \\
0 & D \\
\end{bmatrix} 
\right) 
= 
\left( 
\begin{bmatrix}
1 & \cdots & 1 \\
& \vdots & \ddots \\
& & 1 \\
\end{bmatrix} 
\begin{bmatrix}
I_n & A \\
0 & D \\
\end{bmatrix} 
\right) 
= 
\left( 
\begin{bmatrix}
C' & 0 \\
& \vdots \\
& 0 \\
\end{bmatrix} 
\right)
\]

where \( C' \) is obtained by scaling the bottom row of \( C \) by \( \det(C)^{-1} \). Thus \( C' \) has determinant \( 1 \), and the matrix on the right-hand side of the equation is in the image of \( \text{GL}_n(U)(k) \). Since

\[
n + 1 - d \geq 1 + d + a \geq 1
\]

by assumption, the matrix

\[
\left( 
\begin{bmatrix}
I_d & D \\
0 & D \\
\end{bmatrix} 
\right) 
\left( 
\begin{bmatrix}
1 & \cdots & 1 \\
& \vdots & \ddots \\
& & 1 \\
\end{bmatrix} 
\right)
\]

is contained in \( \text{GL}_{n+1-d}(k) \), and moreover has determinant \( 1 \). Since

\[
n + 1 - a \geq 2d + 1 \geq 2
\]

the matrix

\[
\left( 
\begin{bmatrix}
1 & \cdots & 1 \\
& \vdots & \ddots \\
& & 1 \\
\end{bmatrix} 
\begin{bmatrix}
I_n & A \\
0 & D \\
\end{bmatrix} 
\right)
\]

is contained in \( \text{GL}_{n+1-a}(k) \), and must have determinant \( \det(B)^{-1} \in U \). This concludes the proof of the bound on surjectivity degree.

We next prove the bound on injectivity degree. Let \( n \geq 2d + a + 1 \), and we will show that the map on double cosets

\[
\text{GL}_{n-a}^U(k) \backslash \text{GL}_n^U(k) / \text{GL}_{n-d}(k) \rightarrow \text{GL}_{n+1-a}^U(k) \backslash \text{GL}_{n+1}(k) / \text{GL}_{n+1-d}(k)
\]

is injective. Suppose that \([B]\) and \([C]\) are double cosets in \(\text{GL}_n^U(k)\) that map to the same double coset in \(\text{GL}_{n+1}^U(k)\). Since the map on double cosets is surjective for \(n \geq 2d + a\), we may assume without loss of generality that \([C]\) is represented by a matrix of the form

\[
C = \begin{bmatrix}
    0 & & & \\
    \vdots & \ddots & & \\
    & & 0 & \\
    0 & \cdots & 0 & 1
\end{bmatrix} \in \text{GL}_n^U(k).
\]

Patzt proved that \(\mathcal{M}^{\text{VIC}}(d)\) has injectivity degree 0 by exhibiting matrices \(A \in \text{GL}_{n-a}(k)\) and \(D \in \text{GL}_{n-d}(k)\) so that

\[
\begin{bmatrix}
    I_d \\
    A
\end{bmatrix}
\begin{bmatrix}
    I_d \\
    D
\end{bmatrix}
= C.
\]

Now observe that

\[
\begin{pmatrix}
    1 & & & \\
    \vdots & \ldots & & \\
    & & 1 & \\
    & & \det(D)
\end{pmatrix}
\begin{bmatrix}
    I_d \\
    A
\end{bmatrix}
\begin{pmatrix}
    1 & & & \\
    \vdots & \ldots & & \\
    & & 1 & \\
    & & \det(D)^{-1}
\end{pmatrix}
\begin{pmatrix}
    I_d \\
    D
\end{pmatrix}
= \begin{bmatrix}
    1 & & & \\
    \vdots & \ldots & & \\
    & & 1 & \\
    & & \det(D)
\end{pmatrix}
\begin{bmatrix}
    C' & & & \\
    \vdots & \ldots & & \\
    & & 0 & \\
    & & \cdots & 1
\end{bmatrix}
\begin{pmatrix}
    1 & & & \\
    \vdots & \ldots & & \\
    & & 1 & \\
    & & \det(D)^{-1}
\end{pmatrix}
= \begin{bmatrix}
    C' & & & \\
    \vdots & \ldots & & \\
    & & 0 & \\
    & & \cdots & 1
\end{bmatrix}
\]

where

\[
\begin{bmatrix}
    I_d \\
    D
\end{bmatrix}
\begin{pmatrix}
    1 & & & \\
    \vdots & \ldots & & \\
    & & 1 & \\
    & & \det(D)^{-1}
\end{pmatrix}
\] in \(\text{GL}_{n-d}(k)\) has determinant 1,

and

\[
\begin{bmatrix}
    1 & & & \\
    \vdots & \ldots & & \\
    & & 1 & \\
    & & \det(D)
\end{bmatrix}
\begin{bmatrix}
    I_d & & & \\
    & \cdots & & \\
    & & \cdots & \\
    & & & A
\end{bmatrix}
\] in \(\text{GL}_{n-a}(k)\) has determinant \(\det(C') \det(B)^{-1} \in U\).

Thus \([C]\) and \([B]\) are the same double coset in \(\text{GL}_{n-a}(k) \setminus \text{GL}_n^U(k) / \text{GL}_{n-d}(k)\), and we conclude the bound on injectivity degree. \(\Box\)

From Proposition 2.20 and Proposition 2.21 we will deduce the following results for general \(C\)-modules.

**Proposition 2.22.** Let \(R\) be a field of characteristic zero and \(k\) a finite field. Any \(C\)-module \(A\) over \(R\) generated in degree \(\leq d\) has surjectivity degree \(\leq 2d\). If \(A\) is an induced module over \(\text{VIC}(k)\) or \(\text{SI}(k)\), then \(A\) has injectivity degree \(\leq 0\). Induced \(\text{VIC}^U\)-modules generated in degree \(\leq d\) have injectivity degree \(\leq 2d + 1\).
Proof. Since by Proposition 2.12 any \( C \)-module generated in degree \( \leq d \) can be realized as a quotient of a direct sum of \( C \)-modules \( \mathcal{M}(m) \) with \( m \leq d \), the result follows from Proposition 2.20, Proposition 2.21, and Proposition 2.18. If \( A \) is the \( C \)-module \( \mathcal{M}(W) \) for some \( CB \)-module \( W = \{W_n\} \), then by Proposition 2.12 we can realize \( A \) as a submodule of a direct sum of representable \( C \)-modules \( \mathcal{M}(m) \), and the result again follows from Proposition 2.20, Proposition 2.21, and Proposition 2.18. \( \square \)

The following result shows that the stability degree of a general \( C \)-module is controlled by its presentation degree.

**Proposition 2.23.** Let \( k \) be a finite field, and let \( R \) be a field of characteristic zero. Let \( C \) be \( \text{VlC}(k) \) or \( \text{Sl}(k) \), and suppose that \( A \) is a \( C \)-module over \( R \) with generation degree \( \leq d \) and relation degree \( \leq r \). Then \( A \) has stability degree \( \leq \max(2r, 2d) \). If \( C \) is \( \text{VlC}^U(k) \), and \( A \) is a \( C \)-module over \( R \) with generation degree \( \leq d \) and relation degree \( \leq r \), then \( A \) has stability degree \( \leq \max(2r, 2d + 1) \).

**Proof.** By assumption, there exists a partial resolution of \( A \) by induced \( C \)-modules

\[
\mathcal{M}^1 \rightarrow \mathcal{M}^0 \rightarrow A
\]

with \( \mathcal{M}^1 \) generated in degree \( \leq r \) and \( \mathcal{M}^0 \) generated in degree \( \leq d \). When \( C \) is \( \text{VlC}(k) \) or \( \text{Sl}(k) \), \( \mathcal{M}^1 \) and \( \mathcal{M}^0 \) have injectivity degree \( \leq 0 \) and surjectivities degrees \( \leq 2r \) and \( \leq 2d \), respectively, by Proposition 2.22. When \( C \) is \( \text{VlC}^U(k) \), then by Proposition 2.22, \( \mathcal{M}^1 \) has surjectivity degree \( \leq 2d \) and injectivity degree \( \leq 2r + 1 \), while \( \mathcal{M}^0 \) has surjectivity degree \( \leq 2d \) and injectivity degree \( \leq 2d + 1 \). The proof follows from Proposition 2.19. \( \square \)

We will use the following variation of Proposition 2.23 in the proofs of Theorem E and Theorem F.

**Proposition 2.24.** Let \( k \) be a finite field, and let \( R \) be a field of characteristic zero. Suppose that \( A \) is a \( C \)-module with generation degree \( \leq d \) and relation degree \( \leq r \). Then the induced maps on coinvariants

\[
(A_n)_{G_n} \rightarrow (A_{n+1})_{G_{n+1}}
\]

surject for \( n \geq d \) and inject for \( n \geq r \). In particular these induced maps are isomorphisms for all \( n \geq \max(d, r) \).

**Proof.** Suppose first \( A \) is the representable \( C \)-module \( \mathcal{M}(d) \). Then (as in Proposition 2.20 and Proposition 2.21) a basis for the coinvariants \( (A_n)_{G_n} \) is given by the double cosets \( G_n \backslash G_n / G_n - d \); these double cosets are empty for \( n < d \) and a singleton set for \( n \geq d \). Hence the maps

\[
(M(d)_n)_{G_n} \rightarrow (M(d)_{n+1})_{G_{n+1}}
\]

inject for all \( n \geq 0 \) and surject for \( n \geq d \).

Next suppose that \( A \) is an induced \( C \)-module \( \mathcal{M}(W) \) with \( W \) supported in degree \( \leq d \). By Proposition 2.12 we can realize \( A \) as both a quotient and a submodule of \( C \)-modules of the form \( \bigoplus_{m=0}^d \mathcal{M}(m) \otimes_{Cm} \). Then by combining our results on \( \mathcal{M}(d) \) with the proof of Proposition 2.18 in the special case \( a = 0 \), we find that the maps on coinvariants

\[
(M(W)_n)_{G_n} \rightarrow (M(W)_{n+1})_{G_{n+1}}
\]

also must inject for all \( n \geq 0 \) and surject for \( n \geq d \).
Now consider a general \( C \)-module \( A \) that has a partial resolution by induced \( C \)-modules
\[
\mathcal{M}^1 \rightarrow \mathcal{M}^0 \rightarrow A
\]
with \( \mathcal{M}^1 \) generated in degree \( \leq r \) and \( \mathcal{M}^0 \) generated in degree \( \leq d \). By applying the proof of Proposition 2.22 in the special case that \( a = 0 \), we find that the maps
\[
(A_n)_{G_n} \rightarrow (A_{n+1})_{G_{n+1}}
\]
must inject for \( n \geq r \) and surject for \( n \geq d \), as claimed. \( \square \)

2.3. **Bounding syzygies of \( C \)-modules over characteristic zero.** In this subsection, we will bound the degrees of the modules of higher syzygies of \( C \)-modules presented in finite degree.

**Proposition 2.25.** Let \( k \) be a finite commutative ring, let \( R \) be a field of characteristic zero, and let \( A \) be a \( C \)-module over \( R \) of weight \( \leq d \) and stability degree \( \leq s \). Then \( A \) is generated in degree \( \leq (s + d) \).

The following proof uses methods similar to those used by Church–Ellenberg–Farb [CEF15, Proposition 3.3.3] to show that bounds on weight and stability degree of an \( FI \)-module imply a form of multiplicity stability.

**Proof.** By Proposition 2.10, proving that \( A \) is generated in degree at most \((s + d)\) is equivalent to showing that the induced map
\[
I_n : \text{Ind}^{G_{n+1}}_{G_n} A_n \rightarrow A_{n+1}
\]
surjects for \( n \geq s + d \).

Let \( C_{n+1} \) denote the cokernel of this map; our objective is to show that \( C_{n+1} = 0 \) for \( n \geq s + d \).

Recall the definition of stability degree \( \leq s \): for each \( a \geq 0 \),
\[
(A_n)_{G_{n-a}} \xrightarrow{\mathsf{m}} (A_{n+1})_{G_{n+1-a}} \quad \text{for all } n \geq s + a.
\]

This map of coinvariants factors as follows,
\[
(A_n)_{G_{n-a}} \rightarrow \left( \text{Ind}^{G_{n+1}}_{G_n} A_n \right)_{G_{n+1-a}} \xrightarrow{(I_n)_{G_{n+1-a}}} (A_{n+1})_{G_{n+1-a}}.
\]

Since this composite map surjects for \( n \geq s + a \) by assumption, it follows that the map
\[
\left( \text{Ind}^{G_{n+1}}_{G_n} A_n \right)_{G_{n+1-a}} \xrightarrow{(I_n)_{G_{n+1-a}}} (A_{n+1})_{G_{n+1-a}}
\]
surjects once \( n \geq s + a \), and its cokernel vanishes for any \( a \geq 0 \). Taking coinvariants is right exact, so this cokernel is \((C_{n+1})_{GL_{n+1-a}}\).

Set \( a = d \). By Lemma 2.16, since \( C_{n+1} \) is a quotient of \( A_{n+1} \) and \( A \) has weight \( \leq d \), the vanishing of \((C_{n+1})_{G_{n+1-a}}\) for \( n \geq s + d \) ensures the vanishing of \( C_{n+1} \) for \( n \geq s + d \). We conclude that \( A \) is generated in degree \( \leq (s + d) \). \( \square \)

**Theorem 2.26.** Let \( C \) be \( SL(k) \) or \( SLIC(k) \). Let \( k \) be a finite field, and let \( R \) be a field of characteristic zero. Let \( A \) be a \( C \)-module over \( R \) with generation degree \( \leq d \) and relation degree \( \leq r \). Then there exists a resolution of \( A \) by induced modules \( \mathcal{M}^k \)
\[
\cdots \rightarrow \mathcal{M}^2 \rightarrow \mathcal{M}^1 \rightarrow \mathcal{M}^0 \rightarrow A
\]
where \( \mathcal{M}^0 \) is generated in degree \( \leq d \), and for \( k \geq 1 \), \( \mathcal{M}^k \) is generated in degree \( \leq 3^{k-1}r \).
Proof. By assumption we have a short exact sequence $0 \rightarrow \mathcal{K}^0 \rightarrow \mathcal{M}^0 \rightarrow \mathcal{A}$ with $\mathcal{M}^0$ an induced $\mathbb{C}$–module generated in degree $\leq d$ and the kernel $\mathcal{K}^0$ generated in degree $\leq r$. So we can extend the resolution by constructing a map $\mathcal{M}^1 \rightarrow \mathcal{K}^0$ where $\mathcal{M}^1$ is an induced $\mathbb{C}$–module generated in degree $\leq r$.

We proceed by strong induction. Suppose we have an exact sequence

$$\cdots \rightarrow \mathcal{K}^i \hookrightarrow \mathcal{M}^i \twoheadrightarrow \cdots \rightarrow \mathcal{K}^2 \hookrightarrow \mathcal{M}^2 \twoheadrightarrow \mathcal{K}^1 \hookrightarrow \mathcal{M}^1 \twoheadrightarrow \mathcal{K}^0 \hookrightarrow \mathcal{M}^0 \rightarrow \mathcal{A}$$

where $\mathcal{M}_i$ is an induced $\mathbb{C}$–module generated in degree $\leq 3^i-1r$ for $i \leq k$. In particular $\mathcal{M}^k$ is generated in degree $\leq 3^k-1r$, so it has weight $\leq 3^k-1r$ by Remark 2.15 and injectivity degree 0 by Proposition 2.22. The kernel

$$\mathcal{K}^k \hookrightarrow \mathcal{M}^k \twoheadrightarrow \mathcal{M}^{k-1},$$

being a submodule of $\mathcal{M}^k$, has weight $\leq 3^k-1r$ by Remark 2.14 and injectivity degree 0 by Proposition 2.19. The module $\mathcal{M}^k$ has stability degree $\leq (2)3^k-1r$ by Proposition 2.22, so by Proposition 2.19 the kernel $\mathcal{K}^k$ has surjectivity degree $\leq (2)3^k-1r$. Then by Proposition 2.25 the kernel $\mathcal{K}^k$ is generated in degree

$$\leq (2)3^k-1r + 3^k-1r = 3^k r.$$

This implies that we may choose $\mathcal{M}^{k+1}$ to be an induced $\mathbb{C}$–module generated in degree $\leq 3^k r$, which concludes the inductive step. The resulting resolution is shown in Figure 1.

![Figure 1: Bounds on the syzygies of a VIC(k) or Sl(k)-module A presented in finite degree.](image)

Remark 2.27. The same inductive argument given for Theorem 2.26 can also be used to show that if $\mathcal{A}$ is generated in degree $\leq d$ and has injectivity degree $\leq s$, then we can construct a resolution of $\mathcal{A}$ by induced $\mathbb{C}$–modules with $\mathcal{M}^k$ generated in degree $\leq \max(3kd, 3^{k-1}(s + d))$.

Theorem 2.28. Let $\mathcal{C}$ be VIC$^U(k)$. Let $k$ be a finite field, and let $R$ be a field of characteristic zero. Let $\mathcal{A}$ be a $\mathcal{C}$–module over $R$ with generation degree $\leq d$ and relation degree $\leq r$. Then there exists a resolution of $\mathcal{A}$ by induced modules $\mathcal{M}^k$

$$\rightarrow \mathcal{M}^{k} \rightarrow \cdots \rightarrow \mathcal{M}^2 \rightarrow \mathcal{M}^1 \rightarrow \mathcal{M}^0 \rightarrow \mathcal{A}$$

where $\mathcal{M}^0$ is generated in degree $\leq d$, $\mathcal{M}^1$ is generated in degree $\leq r$, and for $k \geq 2$, $\mathcal{M}^k$ is generated in degree $\leq (2)3^{k-2} \max(r, d) + 3^{k-2}r + \frac{1}{2}(3^{k-1} - 1)$.

Proof. The proof proceeds by the same argument as Theorem 2.26, using the bounds in Proposition 2.21 in place of Proposition 2.20. In the case that $d \leq r$, these bounds are shown in Figure 2.

In the case that $d > r$, the bounds are shown in Figure 3. □
Theorem 2.26
Theorem 2.28
and

modules over \( R \) allows us to reformulate 2.4.

Remark 2.30.

Equivalently,

Definition 2.29.

Similarily,

The following proposition summarizes some properties of the functor \( H_0^C \). Several parts are analogous to [CEF15, Definition 2.3.7 and Remark 2.3.8].

Proposition 2.31. Let \( R \) be a commutative ring and consider the categories of \( C \)-modules and \( CB \)-modules over \( R \). The functor \( H_0^C : C \text{-Mod} \to CB \text{-Mod} \) satisfies the following.

i) A \( C \)-module \( A \) is generated in degree \( \leq d \) if and only if \( H_0^C(A) \) is supported in degree \( \leq d \).

ii) Suppose \( k \) is a finite commutative ring, \( R \) is a field of characteristic zero, and \( A \) is a \( C \)-module. There are (non-canonical) splittings

\[
H_0^C(A)_n \to A_n \quad \text{in each degree } n.
\]
iii) If \( k \) is a finite commutative ring and \( R \) is a field of characteristic zero, then any \( C \)-module \( A \) can be realized as a quotient of the induced module

\[ \mathcal{M}(H^0_0(A)) \rightarrow A. \]

For general commutative rings \( R \) and \( k \), the \( C \)-module \( A \) can be realized as a quotient of the induced module

\[ \mathcal{M}\left(\{A_n \mid n \in \text{support}(H^0_0(A))\}\right) \rightarrow A. \]

iv) The functor \( H^0_0 \) is a left inverse to the functor \( \mathcal{M} \), that is,

\[ H^0_0(\mathcal{M}(W)) = W \quad \text{for all CB–modules } W. \]

v) The functor \( H^0_0 \) is the left adjoint to the inclusion of categories

\[ \iota : \text{CB–Mod} \rightarrow \text{C–Mod}, \]

where \( \iota \) is defined such that non-isomorphism \( C \) morphisms act on \( \iota(W) \) by zero.

vi) The functor \( H^0_0 \) is right exact. Hence, the same is true of \( H^0_0 \) when viewed as a functor

\[ H^0_0 : \text{C–Mod} \rightarrow \text{C–Mod}. \]

Proof. By definition, \( H^0_0(A)_n = 0 \) only if the \( R[\mathcal{G}_n] \)-module \( A_n \) is generated by the image of \( A_{n-1} \).

Hence Part i) follows from Proposition 2.10 Part (b). Part ii) follows because \( R[\mathcal{G}_n] \) is semi-simple by assumption, so the natural surjections \( A_n \rightarrow H^0_0(A)_n \) split. The map \( \{H^0_0(A)_n\} \rightarrow \{A_n\} \) of CB–modules constructed in Part ii) then induces the map of \( C \)-modules \( \mathcal{M}(H^0_0(A)) \rightarrow A \) of Part iii), and (as in the equivalence of Proposition 2.10 Part (d) and Part (e)) it is not difficult to deduce from the definition of \( H^0_0 \) that this map must surject. More generally, there is a surjective map of \( C \)-modules

\[ \mathcal{M}\left(\{A_n \mid n \in \text{support}(H^0_0(A))\}\right) \rightarrow A \]

by an argument similar to the proof of Proposition 2.10 Part (e).

Part iv) can be verified directly from the formula for \( \mathcal{M}(W) \). Part v) follows as in [CEF15, Definition 2.3.7 and Remark 2.3.8]. To deduce Part vi), observe that \( H^0_0 : \text{C–Mod} \rightarrow \text{CB–Mod} \) is the left adjoint to \( \iota \), and therefore right exact [Wei95, Theorem 2.6.1]. Since exactness is defined pointwise on \( C \)-modules, the same result implies that \( H^0_0 \) is exact as a functor \( \text{C–Mod} \rightarrow \text{C–Mod}. \)

By Proposition 2.31 vi), we may make the following definition.

**Definition 2.32.** Define the functors \( H^*_0 : \text{C–Mod} \rightarrow \text{C–Mod} \) to be the left derived functors of \( H^0_0 \).

To compute the \( C \)-homology of a \( C \)-module \( A \), we may take an acyclic resolution \( \mathcal{P}^* \rightarrow A \), apply \( H^0_0 \) to each term and pass to homology. The following proposition shows that we take the terms \( \mathcal{P}^i \) to be any induced modules.

**Proposition 2.33.** Induced \( C \)-modules over \( R \) are \( H^*_0 \)-acyclic.

**Proof.** Let \( W \) be a CB–module. It suffices to show that \( H^k_0(\mathcal{M}(W)) = 0 \) for all \( k > 0 \). Let

\[ \cdots \rightarrow P^2 \rightarrow P^1 \rightarrow P^0 \rightarrow W \]
be a projective resolution of $W$ by $\text{CB}$–modules. Since $\mathcal{M}$ is exact by Proposition 2.8, we can promote this resolution to a resolution of $\mathcal{M}(W)$ by induced $\mathbb{C}$–modules

$$\cdots \longrightarrow \mathcal{M}(P^2) \longrightarrow \mathcal{M}(P^1) \longrightarrow \mathcal{M}(P^0) \longrightarrow \mathcal{M}(W).$$

By Proposition 2.7, this is a projective resolution. Applying $H^0_\mathbb{C}$, however, recovers our original resolution

$$\cdots \longrightarrow P^2 \longrightarrow P^1 \longrightarrow P^0.$$ 

This resolution is exact by construction, and so we find $H^0_\mathbb{C}(\mathcal{M}(W)) = H_k(P^*) = 0$ for $k > 0$. 

**Proposition 2.34.** Let $R$ be a field of characteristic zero and $\mathbf{k}$ a finite field. Let $\mathcal{A}$ be a $\mathbb{C}$–module over $R$ generated in degree $\leq d$ and related in degree $\leq r$. Then $H^0_\mathbb{C}(\mathcal{A})_V$ vanishes for $\dim_k V > d$ and $H^1_\mathbb{C}(\mathcal{A})_V$ vanishes for $\dim_k V > r$.

- If $\mathcal{C}$ is SI($k$) or VIC($k$), then for $k \geq 1$, the groups $H^0_\mathbb{C}(\mathcal{A})_V$ vanish once $\dim_k V > 3^{k-1}r$.
- If $\mathcal{C}$ is VIC$^U(k)$, then for $k \geq 2$, the groups $H^1_\mathbb{C}(\mathcal{A})_V$ vanish once

  $$\dim_k V > (2)3^{k-2} \max(r,d) + 3^{k-2}r + \frac{1}{2}(3^{k-1} - 1).$$

**Proof.** By Proposition 2.33, we can compute $H^0_\mathbb{C}(\mathcal{A})_d$ by resolving $\mathcal{A}$ by induced $\mathbb{C}$–modules, applying the functor $H^0_\mathbb{C}$ and taking homology. The result follows from applying $H^0_\mathbb{C}$ to the resolution described in Theorem 2.26 or Theorem 2.28. 

The following proposition relates the vanishing of $H^0_\mathbb{C}(\mathcal{A})_n$ and $H^1_\mathbb{C}(\mathcal{A})_n$ to the generation and relation degree of a $\mathbb{C}$–module $\mathcal{A}$.

**Proposition 2.35.** Suppose that $\mathcal{A}$ is a $\mathbb{C}$–module such that $H^0_\mathbb{C}(\mathcal{A})_n = 0$ for $n > d$ and $H^1_\mathbb{C}(\mathcal{A})_n = 0$ for $n > r$. Then $\mathcal{A}$ is generated in degree $\leq d$ and related in degree $\leq \max(r,d)$.

**Proof.** Proposition 2.31 implies that $\mathcal{A}$ is generated in degree $\leq d$ and that we can find a short exact sequence

$$0 \rightarrow \mathcal{K} \rightarrow \mathcal{M} \rightarrow \mathcal{A} \rightarrow 0$$

with $\mathcal{M}$ an induced $\mathbb{C}$–module which is generated in degree $\leq d$. Consider the associated long exact sequence on homology

$$\cdots \longrightarrow H^0_\mathbb{C}(\mathcal{A})_n \longrightarrow H^0_\mathbb{C}(\mathcal{K})_n \longrightarrow H^0_\mathbb{C}(\mathcal{M})_n \longrightarrow H^0_\mathbb{C}(\mathcal{A})_n \longrightarrow 0.$$

Since $H^0_\mathbb{C}(\mathcal{A})_n = 0$ for $n > r$ and $H^0_\mathbb{C}(\mathcal{M})_n = 0$ for $n > d$, it follows that $H^0_\mathbb{C}(\mathcal{K})_n$ must vanish for $n > \max(r,d)$. The claim follows by Proposition 2.31 i).

Combining Proposition 2.34 and Proposition 2.35 establishes Theorem C and Theorem D.

The following corollaries were suggested to us by Eric Ramos. We state these without explicit ranges although the proofs we give can easily be made effective.

**Corollary 2.36.** Let $\mathbf{k}$ be a finite field and $R$ a field of characteristic zero. Let $\mathcal{C}$ be one of the categories SI($k$) or VIC$^U(k)$. Then the category of $\mathbb{C}$–modules presented in finite degree is an abelian category.
Proof. Let \( f : A \to B \) be a map between \( C \)-modules presented in finite degree. We must check that \( \ker(f) \) and \( \text{coker}(f) \) are presented in finite degree. Note that without any assumptions on \( R \) and \( k \), it is true that the cokernel of a map of \( C \)-modules presented in finite degree is presented in finite degree.

By Theorem C in the case of \( \text{SI} \) and Theorem D in the case of \( \text{VIC} \), we see that \( H^C_C(\text{coker}(f))_n \cong 0 \) for \( n \) sufficiently large. By considering the long exact sequence of \( C \)-homology groups associated to the short exact sequence

\[
0 \to \text{im}(f) \to B \to \text{coker}(f) \to 0,
\]

we see that \( H^C_C(\text{im}(f))_n \cong H^C_0(\text{im}(f))_n \cong 0 \) for \( n \) sufficiently large. Theorem C and Theorem D imply that \( H^C_C(\text{im}(f))_n \cong 0 \) for \( n \) sufficiently large. By considering the long exact sequence of \( C \)-homology groups associated to the short exact sequence

\[
0 \to \ker(f) \to A \to \text{im}(f) \to 0,
\]

we see that \( \ker(f) \) is presented in finite degree.

\[\square\]

Corollary 2.37. Let \( k \) be a finite field and \( R \) a field of characteristic zero. Let \( C \) be one of the categories \( \text{SI}(k) \) or \( \text{VIC}^U(k) \). Let \( B \) be a \( C \)-module and \( A \) a \( C \)-submodule. If \( A \) has finite generation degree and \( B \) has finite presentation degree, then \( A \) has finite presentation degree.

Proof. Let \( K \) denote \( B/A \). By considering the long exact sequence in \( C \)-homology associated to

\[
0 \to A \to B \to K \to 0,
\]

we see that \( K \) has finite presentation degree. Thus, by Theorem C and Theorem D, \( H^C_C(K)_n \cong 0 \) for \( n \) sufficiently large. By again considering the long exact sequence in \( C \)-homology associated to

\[
0 \to A \to B \to K \to 0,
\]

we see that \( A \) has finite presentation degree. \[\square\]

3. Representation stability results

In this section, we apply the algebraic tools developed in the previous section to prove our representation stability theorems.

3.1. Central stability homology. Central stability homology is an invariant of modules over categories such as \( \text{SI}(k) \) or \( \text{VIC}(k) \). In the context of \( \text{SI}(k) \)-modules and \( \text{VIC}(k) \)-modules, it was introduced by Putman–Sam [PS14], though the name central stability homology is due to Patzt [Pat17], based on earlier terminology in the work of Putman [Put15]. In this subsection, we describe basic properties of central stability homology. After a draft of this paper was circulated, we were informed that many of the results of this subsection were independently established by Patzt [Pat17]. In the interest of space, we will not reprove these properties.

Let \( \Delta' \) denote the augmented semi-simplicial category, the category of finite ordered sets and order-preserving injections. We will pick inclusions \( s : \Delta' \to \text{SI}(k) \) and \( v : \Delta' \to \text{VIC}(k) \) as follows. Given an ordered set \( X \), let \( s(X) \) be the free \( k \)-module on \( X \sqcup X \) with \( X \sqcup X \) a symplectic basis. Inclusions of sets induce symplectic embeddings by extending linearly. Let \( v(X) \) be the free \( k \)-module on \( X \). Given
an order preserving injection $\iota : X \to Y$, let $T : v(X) \to v(Y)$ be the linear map induced by $\iota$ and let $C$ be span $(Y - \text{im}(f))$ in $v(Y)$. Define $v(\iota)$ to be $(T, C)$.

**Definition 3.1.** Let $\mathcal{A}$ be an $\text{Sl}(k)$–module. We now define a semi-simplicial $\text{Sl}(k)$–module $\mathbf{C}_\bullet(\mathcal{A})$ whose value on an ordered set $X$ and a symplectic $k$–module $V$ is given by the formula

$$\mathbf{C}_X(\mathcal{A})_V = \bigoplus_{T \in \text{Hom}_{\text{Sl}(k)}(\iota(X), V)} \mathcal{A}(\text{im}(T)\perp).$$

Composition induces the semi-simplicial and $\text{Sl}(k)$–module structure.

Similarly for $\mathcal{A}$ a $\text{VIC}^U(k)$–module, we define $\mathbf{C}_\bullet(\mathcal{A})$ by the formula

$$\mathbf{C}_X(\mathcal{A})_V = \bigoplus_{(T, C) \in \text{Hom}_{\text{VIC}^U(k)}(\iota(X), V)} \mathcal{A}(C).$$

Let $\mathbf{C}_i(\mathcal{A})_V$ denote $\mathbf{C}_X(\mathcal{A})_V$ for $X = \{0, \ldots, i\}$. Let $\mathbf{C}_\bullet(\mathcal{A})_V$ denote the chain complex formed by taking the alternating sum of the face maps and let $H_i(\mathbf{C}_\bullet(\mathcal{A})_V)$ denote its homology $H_i(\mathbf{C}_\bullet(\mathcal{A})_V)$. We call the chain complex $\mathbf{C}_\bullet(\mathcal{A})$ the *central stability chains* on $\mathcal{A}$ and call its homology $H_\bullet(\mathbf{C}_\bullet(\mathcal{A}))$ the *central stability homology*.

Central stability homology is closely related to $\text{Sl}$–homology and $\text{VIC}^U$–homology, and both control the generation degrees of the modules of syzygies.

Patzt [[Pat17, Theorem 5.7]] gave a general criterion for results of the form of the following Theorem 3.2 to hold for a broad class of categories $\mathcal{C}$. He verifies the criterion for the categories $\text{Sl}(k)$ and $\text{VIC}(k)$ [[Pat17, Remark 5.6]]. Miller–Patzt–Wilson [[MPW17, Proposition 3.14]] verified the criterion in the case $\mathcal{C} = \text{VIC}^U(k)$.

**Theorem 3.2** (Patzt [[Pat17, Theorem 5.7]], Miller–Patzt–Wilson [[MPW17, Proposition 3.14]])

*Let $\mathcal{A}$ be an $\text{Sl}(k)$–module with $k$ a field. Let $d_0, \ldots, d_k$ be integers with $d_{i+1} - d_i \geq 3$. Then the following are equivalent.*

1. There is an exact sequence of $\text{Sl}(k)$–modules

$$\mathcal{W}^k \to \mathcal{W}^{k-1} \to \cdots \to \mathcal{W}^0 \to \mathcal{A} \to 0$$

with $\mathcal{W}^i$ induced and generated in degrees $\leq d_i$.

2. $H_i(\mathcal{A})_n = 0$ for $n > d_{i+1}$ for all $i < k$.

*Let $\mathcal{A}$ be a $\text{VIC}^U(k)$–module with $k$ a field. Let $d_0, \ldots, d_k$ be integers with $d_{i+1} - d_i \geq 2$. Then the following are equivalent.*

1. There is an exact sequence of $\text{VIC}^U(k)$–modules

$$\mathcal{W}^k \to \mathcal{W}^{k-1} \to \cdots \to \mathcal{W}^0 \to \mathcal{A} \to 0$$

with $\mathcal{W}^i$ induced and generated in degrees $\leq d_i$.

2. $H_i(\mathcal{A})_n = 0$ for $n > d_{i+1}$ for all $i < k$.

The following is a reformulation of work of Randal-Williams–Wahl [[RWW17, Lemma 5.9]] and Mirzaii–van der Kallen [[MvdK02, Theorem 7.4]]. See also Miller–Patzt–Wilson [[MPW17, Proposition 3.14]]. It is a slight sharpening of the above theorem for the induced module $\mathcal{M}(0)$.
Proposition 3.3 (Patzt [Pat17, Remark 5.6]). Let $k$ be a field. Then $H_i(M^S(0))_n \cong 0$ for $n > 2i + 3$ and $H_i(M^{WCG}(0))_n \cong 0$ for $n > 2i + 2$.

3.2. Stability for congruence subgroups.

3.2.1. Congruence subgroups of mapping class groups. Putman–Sam [PS14, Corollary 6.22] observe that the representations $H_i(\text{Mod}(\Sigma_{g,1}, p); R)$ assemble to form an $\text{SL}(\mathbb{Z}/p\mathbb{Z})$–module over $R$. We denote this $\text{SL}(\mathbb{Z}/p\mathbb{Z})$–module by $H_i(\text{Mod}(\Sigma, p); R)$.

We prove our results on congruence subgroups using spectral sequences introduced by Putman–Sam [PS14]. The following is implicit in the proof of [PS14, Theorem K] and builds on [PS14, Theorem 5.13, Lemma 6.24, Theorem 6.25]. See also Patzt [Pat17, Corollary 8.5] and Miller–Patzt–Wilson [MPW17, Proposition 3.38].

Theorem 3.4 (Putman–Sam [PS14]). For each $g > 0$, there is a homologically graded spectral sequence $E^n_{a,b}(g)$ satisfying the following properties.

i) $E^n_{a,b}(g) \cong 0$ for $a < -1$ or $b < 0$.

ii) $E^2_{a,b}(g) \cong H_a(H_b(\text{Mod}(\Sigma, p); R))_g$.

iii) $E^2_{a,b}(g) \cong 0$ for $a + b \leq \frac{g-3}{2}$.

The $E^2$ page is illustrated in Figure 4.

\begin{figure}[h]
\centering
\begin{tabular}{cccc}
3 & $H_{-1}(H_3(\text{Mod}(\Sigma, p); R))_g$ & $H_0(H_3(\text{Mod}(\Sigma, p); R))_g$ & $H_1(H_3(\text{Mod}(\Sigma, p); R))_g$ & $H_2(H_3(\text{Mod}(\Sigma, p); R))_g$

2 & $H_{-1}(H_2(\text{Mod}(\Sigma, p); R))_g$ & $H_0(H_2(\text{Mod}(\Sigma, p); R))_g$ & $H_1(H_2(\text{Mod}(\Sigma, p); R))_g$ & $H_2(H_2(\text{Mod}(\Sigma, p); R))_g$

1 & $H_{-1}(H_1(\text{Mod}(\Sigma, p); R))_g$ & $H_0(H_1(\text{Mod}(\Sigma, p); R))_g$ & $H_1(H_1(\text{Mod}(\Sigma, p); R))_g$ & $H_2(H_1(\text{Mod}(\Sigma, p); R))_g$

0 & $H_{-1}(H_0(\text{Mod}(\Sigma, p); R))_g$ & $H_0(H_0(\text{Mod}(\Sigma, p); R))_g$ & $H_1(H_0(\text{Mod}(\Sigma, p); R))_g$ & $H_2(H_0(\text{Mod}(\Sigma, p); R))_g$

\end{tabular}
\end{figure}

We now prove the following strengthening of Theorem A.

Theorem 3.5. Let $R$ be a field of characteristic zero and $p$ be a prime. The $\text{SL}(\mathbb{Z}/p\mathbb{Z})$–module $H_0(\text{Mod}(\Sigma, p); R) \cong M^S(0)$ is generated in degree $\leq 0$ and has no relations. The $\text{SL}(\mathbb{Z}/p\mathbb{Z})$–module $H_1(\text{Mod}(\Sigma, p); R)$ is generated in degree $\leq 5$ and related in degree $\leq 8$. For $i > 1$, the $\text{SL}(\mathbb{Z}/p\mathbb{Z})$–module $H_i(\text{Mod}(\Sigma, p); R)$ is generated in degree $\leq (8)^{3^{2i-3}}$ and related in degree $\leq (8)^{3^{2i-2}}$.

Proof. We proceed by induction on $i$. Since $H_0(\text{Mod}(\Sigma, p); R) \cong M^S(0)$, by Proposition 3.3,

$E^2_{a,0} \cong H_a(H_0(\text{Mod}(\Sigma, p); R))_g = 0$ for $g > 2a + 3$. 

Now consider the $b = 1$ row of the spectral sequence, which corresponds to the homology of $\text{Mod}(\Sigma, p)$ in degree $i = 1$. This row requires some additional care, so we will show explicitly how to bound the vanishing of these central stability homology groups. Once $g \geq 3$, $E^\infty_{1,1}(g) = 0$ by Theorem 3.4. But for $g > 5$, the group $E^2_{1,0}(g) \cong H_1(H_0(\text{Mod}(\Sigma, p); R))_g$ vanishes, and so in this range there are no nonzero differentials into our out of the groups $E^r_{1,1}(g)$ for any $r \geq 2$. Thus

$$E^2_{1,1}(g) \cong H_{-1}(H_1(\text{Mod}(\Sigma, p); R))_g = 0 \quad \text{for } g > 5.$$ 

Similarly $E^\infty_{0,1}(g) = 0$ for $g > 5$ and for $r \geq 2$ the domain $E^r_{2,0}(g)$ of the only possible nonzero differential to or from $E^r_{0,1}(g)$ vanishes for $g > 7$. Thus

$$H_0(H_1(\text{Mod}(\Sigma, p); R))_g = 0 \quad \text{for } g > 7.$$ 

See Figure 5.

![Diagram](image)

**Figure 5.** Page $E^2_{p,q}(g)$ for $g \geq 8$.

If we replace the condition $g > 7$ with the weaker condition $g > 8$, then these two central stability homology groups satisfy the hypotheses of Patzt’s Theorem 3.2, and we obtain a partial resolution of induced $\text{Sl}(\mathbb{Z}/p\mathbb{Z})$–modules

$$\mathcal{M}^1 \longrightarrow \mathcal{M}^0 \longrightarrow H_1(\text{Mod}(\Sigma, p); R) \longrightarrow 0$$

with $\mathcal{M}^0$ generated in degree $\leq 5$ and $\mathcal{M}^1$ generated in degree $\leq 8$.

We now proceed with the inductive step. Suppose that $j > 1$ and that $H_i(\text{Mod}(\Sigma, p); R)$ is generated in degree $\text{max}(5, (8)3^{2i-3})$ and related in degree $\leq (8)3^{2i-2}$ for all $1 \leq i < j$. Then Theorem 3.2 implies that there is a partial resolution of $H_i(\text{Mod}(\Sigma, p); R)$ by induced $\text{Sl}(\mathbb{Z}/p\mathbb{Z})$–modules with term $\mathcal{M}^0$ generated in degree $\text{max}(5, (8)3^{2i-3})$ and $\mathcal{M}^1$ generated in degree $\leq (8)3^{2i-2}$. It follows by Theorem 2.26 that we can extend this partial resolution to a resolution by induced modules with term $\mathcal{M}^k$ generated in degree $\leq (8)(3^{2i-2})(3^{k-1})$. Then Theorem 3.2 implies that $H_k(H_i(\text{Mod}(\Sigma, p); R))_g$ vanishes for $g > (8)(3^{2i-2})(3^k)$. Small values of these bounds are shown in Figure 6, with some differentials superimposed.

In particular, $E^2_{2i+1+r, j-r+1}(g) = H_{-1+r}(H_{j-r+1}(\text{Mod}(\Sigma, p); R))_g$ vanishes for $g > (8)(3^{2j-r+1})^2(3^{r-1})$ for $2 \leq r \leq j+1$, so there are no nonzero differentials to or from $E^r_{-1,j}(g)$ once $r \geq 2$ and $g > (8)(3^{2j-3})$. Since $E^\infty_{-1,j}(g) = 0$ in this range, we conclude that

$$E^2_{-1,j}(g) = H_{-1}(H_j(\text{Mod}(\Sigma, p); R))_g = 0 \quad \text{for } g > (8)(3^{2j-3}).$$
Theorem 3.2. The groups $\text{PS}14$ then implies that generated in degree $\leq 1$, so there are no nonzero differentials to or from $E^{r}_{0,j}(g)$ once $r \geq 2$ and $g > (8)(3^{2j-2})$. Again $E^{\infty}_{0,j}(g) = 0$ in this range, so we conclude that $E^{2}_{0,j}(g) = H_{0}(H_{j}(\text{Mod}(\Sigma, p); R))_{0} = 0$ for $g > (8)(3^{2j-2})$.

Finally, Theorem 3.2 then implies that $H_{j}(\text{Mod}(\Sigma, p); R)$ is generated in degree $\leq (8)(3^{2j-3})$ and related in degree $\leq (8)(3^{2j-2})$, which concludes the inductive step. 

3.2.2. Congruence subgroups of automorphism groups of free products. Putman–Sam [PS14, Corollary 6.7] observed that the representations $H_{k}(\text{Aut}(F_{n}, p); R)$ assemble to form a $\text{VIC}^{\pm}(\mathbb{Z}/p\mathbb{Z})$–module over $R$ which we will denote by $H_{k}(\text{Aut}(F, p); R)$. Implicitly in the proof of [PS14, Theorem I] and building on [PS14, Theorem 5.13, Lemma 6.8, Theorem 6.9], Putman–Sam proved the following.

Theorem 3.6 (Putman–Sam [PS14]). For all $n$, there is a homologically graded spectral sequence $E_{a,b}^{r}(n)$ satisfying the following properties.

i) $E_{a,b}^{r}(n) \cong 0$ for $a < -1$ or $b < 0$.

ii) $E_{a,b}^{r}(n) \cong H_{a}(H_{b}(\text{Aut}(F, p); R))_{n}$.

iii) $E_{a,b}^{\infty}(n) \cong 0$ for $a + b \leq \frac{n-3}{2}$.

The following implies Theorem B.

Theorem 3.7. Let $R$ be a field of characteristic zero and $p$ be a prime. Then the $\text{VIC}^{\pm}(\mathbb{Z}/p\mathbb{Z})$–module $H_{0}(\text{Aut}(F, p); R) \cong \mathcal{M}^{\text{VIC}}(0)$ is generated in degree $\leq 0$ and has no relations. The $\text{VIC}^{\pm}(\mathbb{Z}/p\mathbb{Z})$–module $H_{1}(\text{Aut}(F, p); R)$ is generated in degree $\leq 4$ and related in degree $\leq 6$. For $i > 1$, the $\text{VIC}^{\pm}(\mathbb{Z}/p\mathbb{Z})$–module $H_{i}(\text{Aut}(F, p); R)$ is generated in degree $\leq (\frac{14}{2})3^{2i-3} - \frac{1}{2}$ and related in degree $\leq (\frac{14}{2})3^{2i-2} - \frac{1}{2}$.

Proof. Since $H_{0}(\text{Aut}(F, p); R) \cong \mathcal{M}(0)$, these groups are generated in degree $\leq 0$ and have no relations. The bottom row of the $E^{2}(n)$ page, $E_{k,0}^{2}(n) \cong H_{k}(H_{0}(\text{Aut}(F, p); R))$, vanishes for $n > 2k + 2$ by Proposition 3.3. The groups $E_{1,1}^{r}(n)$ converge to zero for $n \geq 3$, and the only possible nonzero differential to or from these groups has domain $E_{1,0}^{r}(n) \cong H_{1}(H_{0}(\text{Aut}(F, p); R))_{n}$, which vanishes for.
n > 4. Hence $E^2_{1,1}(n) \cong H_{-1}(H_1(\text{Aut}(F, p); R))_n = 0$ for $n > 4$. Similarly the groups $E^n_{0,1}(n)$ converge to zero for $n \geq 5$ and admit no nonzero differentials for $n > 6$. We conclude

$$H_{-1}(H_1(\text{Aut}(F, p); R))_n = 0 \quad \text{for } n > 4, \quad \text{and} \quad H_0(H_1(\text{Aut}(F, p); R))_n = 0 \quad \text{for } n > 6.$$

By Theorem 3.2, there is a partial resolution $\mathcal{M}^1 \to \mathcal{M}^0 \to H_1(\text{Aut}(F, p); R)$ with $\mathcal{M}^0$ an induced VIC$^\pm(\mathbb{Z}/p\mathbb{Z})$--module generated in degree $\leq 4$, and $\mathcal{M}^1$ an induced VIC$^\pm(\mathbb{Z}/p\mathbb{Z})$--module generated in degree $\leq 6$.

We proceed by induction. Now assume that $j > 1$ and that for all $1 \leq i < j$ we have constructed a partial resolution of the VIC$^\pm(\mathbb{Z}/p\mathbb{Z})$--module $H_i(\text{Aut}(F, p); R)$

$$\mathcal{M}^1 \to \mathcal{M}^0 \to H_i(\text{Aut}(F, p); R)$$

by induced modules with $\mathcal{M}^0$ generated in degree $\leq (\frac{13}{2})3^{2i-2} - \frac{1}{2}$ and $\mathcal{M}^1$ generated in degree $\leq (\frac{13}{2})3^{2i-2} - \frac{1}{2}$. By Theorem 2.28, we can extend this to a resolution $\mathcal{M}^* \to H_i(\text{Aut}(F, p); R)$ by induced VIC$^\pm(\mathbb{Z}/p\mathbb{Z})$--modules with $\mathcal{M}^k$ generated in degree at most

$$\left(3^{k-1} \left(\left(\frac{13}{2}\right)3^{2i-2} - \frac{1}{2}\right) + \frac{1}{2}3^{k-1} - 1\right) = \left(\frac{13}{2}\right)\left(3^{k-1}(3^{2i-2}) - \frac{1}{2}\right)$$

for $k \geq 1$.

Theorem 3.2 then implies that for $k \geq 1$,

$$E^2_{k,i}(n) \cong H_k(H_i(\text{Aut}(F, p); R))_n = 0 \quad \text{for } n > \left(\frac{13}{2}\right)(3^{k}(3^{2i-2}) - \frac{1}{2})$$

In particular, for each $2 \leq r \leq j + 1$,

$$E^2_{1+r,j-r+1}(n) \cong H_{-1+r}(H_{j-r+1}(\text{Aut}(F, p); R))_n = 0 \quad \text{for } n > \left(\frac{13}{2}\right)(3^{2(j-r+1)-2}(3^{-1+r}) - \frac{1}{2})$$

Hence, for $r \geq 2$, there are no nonzero differentials to or from $E^r_{-1,j}(n)$ for $r \geq 2$ and $n > (\frac{13}{2})(3^{2j-3}) - \frac{1}{2})$. Since $E^\infty_{-1,j}(n) = 0$ in this range, we conclude that

$$E^2_{1,j}(n) = H_{-1}(H_j(\text{Aut}(F, p); R))_n = 0 \quad \text{for } n > \left(\frac{13}{2}\right)(3^{2j-3}) - \frac{1}{2}$$

Similarly, for each $2 \leq r \leq j + 1$, the group $E^2_{r,j-r+1}(n) \cong H_r(H_{j-r+1}(\text{Aut}(F, p); R))_n$ vanishes for $n > (\frac{13}{2})(3^{2j-r+1}-2)(3^{r}) - \frac{1}{2}$. This implies that there are no nonzero differentials to or from $E^0_{0,j}(n)$ for $r \geq 2$ and $n > (\frac{13}{2})(3^{2j-r+1}) - \frac{1}{2})$. Again $E^\infty_{0,j}(n) = 0$ in this range, so we conclude that

$$E^2_{0,j}(n) = H_0(H_j(\text{Aut}(F, p); R))_n = 0 \quad \text{for } n > \left(\frac{13}{2}\right)(3^{2j-2}) - \frac{1}{2}$$

By Theorem 3.2, $H_j(\text{Aut}(F, p); R)$ is generated in degree $\leq (\frac{13}{2})(3^{2j-3}) - \frac{1}{2}$ and related in degree $\leq (\frac{13}{2})(3^{2j-2}) - \frac{1}{2})$. This completes the inductive step and concludes the proof.

**Remark 3.8.** Let $G = \pi_1(P)$ with $P$ an orientable prime 3-manifold such that $\text{Mod}(P) \to \text{Aut}(G)$. Examples of such groups include $\mathbb{Z}$, $\mathbb{Z}/2$, $\mathbb{Z}/4$, $\mathbb{Z}/6$, and $\pi_1(\Sigma_g)$; see the introduction of Hatcher–Wahl [HW10]. Many of these groups admit surjections $\phi : G \to \mathbb{Z}/p\mathbb{Z}$ for some prime $p$. Given such a surjection, let $\text{Aut}(G^{*n}, \phi)$ denote the kernel of $\text{Aut}(G^{*n}) \to GL_n(\mathbb{Z}/p\mathbb{Z})$. Here $G^{*n}$ denotes the $n$–fold free product of $G$. An analogous stability result to Theorem 3.7 can be proven for $H_i(\text{Aut}(G^{*n}, \phi); R)$ using [RWW17, Lemma 5.6] to establish the analogue of Part iii) of Theorem 3.6. As it is not known if $H_i(\text{Aut}(G^{*n}, \phi); R)$ is finitely generated for $G \neq \mathbb{Z}$, it is unclear if the Noetherian techniques of Putman–Sam [PS14, Theorem D] apply to $H_i(\text{Aut}(G^{*n}, \phi); R)$ for $G \neq \mathbb{Z}$. 

\[\square\]
4. Twisted stability results

4.1. Tensor products of $\mathbb{C}$–modules. Before we can prove our twisted homological stability theorems, we first must establish some basic algebraic properties of tensor products of $\mathbb{C}U$ and $\mathbb{S}$–modules.

Proposition 4.1. Let $C$ be one of the categories $\mathbb{S} \mathbb{C}(k)$ or $\mathbb{C}U(k)$. Let $A$ and $B$ be $C$–modules over a commutative ring $R$ generated in degrees $\leq d_A$ and $\leq d_B$, respectively. Then $A \otimes_R B$ is generated in degree $d_A + d_B$.

Proof. Proposition 2.12 implies that $A$ and $B$ are quotients of modules of the form $\bigoplus_{m \leq d_A} \mathcal{M}(m)^{\otimes c_m}$ and $\bigoplus_{m \leq d_B} \mathcal{M}(m)^{\otimes d_m}$, respectively, so it suffices to show that $\mathcal{M}(m) \otimes_R \mathcal{M}(m')$ is generated in degree $\leq m + m'$. Assume first that $C$ is $\mathbb{S} \mathbb{C}$. For simplicity we will denote the object $k^{2m}$ by $m$. Let $(f, f')$ be a pair of morphisms in the basis $\text{Hom}_C(m, n) \times \text{Hom}_C(m', n)$ for $\mathcal{M}(m) \otimes_R \mathcal{M}(m')$. Denote the object $p \cong (\text{im}(f) + \text{im}(f'))$; in particular $p$ has rank $\leq 2(m + m')$. Then let $h$ denote the inclusion of $p$ into $n$, completing the following commutative diagram.

\[ \begin{array}{ccc} m & \xrightarrow{f} & p \xrightarrow{h} n \\ g & & g' \downarrow & & \downarrow f' \\ m' & \xrightarrow{f} & p \xrightarrow{h} n \\ g' & & g' \downarrow & & \downarrow f' \\ \end{array} \]

Hence $(f, f') = h_*(g, g')$ with $(g, g') \in (\mathcal{M}(m) \otimes_R \mathcal{M}(m'))_p$, and we see that $\mathcal{M}(m) \otimes_R \mathcal{M}(m')$ is generated in degree $\leq m + m'$ as claimed.

Now fix $U \subseteq k^\times$ and suppose that $C$ is $\mathbb{C}U(k)$. Denote the object $k^m$ by $m$. Let $((f, C_f), (f', C_f'))$ be a pair of morphisms in the basis $\text{Hom}_C(m, n) \times \text{Hom}_C(m', n)$ for $\mathcal{M}(m) \otimes_R \mathcal{M}(m')$. Since $C_f$ and $C_f'$ are respectively $(n - m)$– and $(n - m')$–dimensional subspaces of an $n$–dimensional space, their intersection is at least $(n - m - m')$–dimensional. Let $C$ be a $(n - m - m')$–dimensional subspace of $C_f \cap C_f'$. Again let $p \cong (\text{im}(f) + \text{im}(f'))$. Notably, $p$ is the pushout of the inclusions

\[ f^{-1}|_{\text{im}(f) \cap \text{im}(f')} : \text{im}(f) \cap \text{im}(f') \to m \quad \text{and} \quad (f')^{-1}|_{\text{im}(f) \cap \text{im}(f')} : \text{im}(f) \cap \text{im}(f') \to m. \]

Choose an inclusion of $p$ into $m + m'$. Choose a map $h$ making the following diagram commute such that $\text{im}(h)$ is a complement of $C$. 

\[ \begin{array}{ccc} m \xrightarrow{f} & p \xrightarrow{h} & n \\ \downarrow f^{-1} & & \downarrow (f')^{-1} \\ \text{im}(f) \cap \text{im}(f') & \xrightarrow{h} & m + m' \xrightarrow{h} n \\ \end{array} \]
Now define \( C_g := h^{-1}(\text{im}(h) \cap C_f), C'_g := h^{-1}(\text{im}(h) \cap C'_f) \), and \( C_h := C \). It follows that \((g, C_g), (g', C'_g)\) and \((h, C_h)\) are all \( \text{VIC}^U \) morphisms, and that
\[
\begin{align*}
\mathbf{n} &\cong \left( \text{im}(h) \oplus C \right) \cong \left( \text{im}(f) \oplus \text{im}(h) \cap C_f \right) \oplus C_h, \\
\mathbf{m} + \mathbf{m}' &\cong \left( \text{im}(g) \oplus C_g \right) \cong \left( \text{im}(f) \oplus \text{im}(h) \cap C_f \right) \oplus C_h.
\end{align*}
\]
Hence
\[
(h, C_h)_* \left( (g, C_g), (g', C'_g) \right) = \left( (f, C_f), (f', C'_f) \right)
\]
which gives generation in degree \( m + m' \) as desired. \( \square \)

**Proposition 4.2.** Let \( C = \text{Sl}(k) \) or \( \text{VIC}^U(k) \). Let \( A \) and \( B \) be \( C \)-modules over a commutative ring \( R \) with projective resolutions
\[
\vdash P^A_\bullet \rightarrow P^B_\bullet \rightarrow A \quad \text{and} \quad P^B_\bullet \rightarrow P^B_0 \rightarrow B
\]
such that \( P^A_0 \) and \( P^B_0 \) are generated in degrees \( \leq d_A \) and \( d_B \), respectively, and and \( P^A_1 \) and \( P^B_1 \) are generated in degree \( \leq r_A \) and \( r_B \), respectively.

Then \( A \otimes_R B \) has a projective resolution with the first term generated in degree \( \leq (d_A + d_B) \), and the second term generated in degree \( \leq \max(r_A + d_B, r_B + d_A) \).

Recall from Proposition 2.7 that if \( G_n \) is finite and \( R \) a field of characteristic zero, then all resolutions by induced \( C \)-modules are projective resolutions.

**Proof of Proposition 4.2.** Take the total complex associated to the double complex \( P^A_\bullet \otimes_R P^B_\bullet \). The total complex is exact because the rows and columns of the double complex are, and projective because tensor products of projective objects are projective. So we have a projective resolution
\[
\vdash (P^A_0 \otimes_R P^B_1) \oplus (P^A_1 \otimes_R P^B_0) \rightarrow (P^A_0 \otimes_R P^B_0) \rightarrow A \otimes_R B.
\]
The result follows by Proposition 4.1. \( \square \)

### 4.2. Homological stability with twisted coefficients

In this subsection, we prove Theorem E and Theorem F.

An inclusion of a surface \( \Sigma_{g,1} \) into \( \Sigma_{g+1,1} \) induces a map \( \text{Mod}(\Sigma_{g,1}) \rightarrow \text{Mod}(\Sigma_{g+1,1}) \). If \( A \) is an \( \text{Sl}(\mathbb{Z}/p\mathbb{Z}) \)-module, then this inclusion map gives a map:
\[
H_i(\text{Mod}(\Sigma_{g,1}); A_g) \rightarrow H_i(\text{Mod}(\Sigma_{g+1,1}); A_{g+1}).
\]
See Putman–Sam [PS14, Section 4] for more details on this and the analogous construction in the case of \( \text{Aut}(F_n) \) and \( \text{VIC}^\pm(\mathbb{Z}/p\mathbb{Z}) \)-modules.

**Proof of Theorem E.** Let \( G_g \) denote \( \text{Sp}_2g(\mathbb{Z}/p\mathbb{Z}) \), let \( R \) be a field of characteristic zero, and let \( A \) be an \( \text{Sl}(\mathbb{Z}/p\mathbb{Z}) \)-module over \( R \) with generation degree \( d \) and relation degree \( r \). Given a group \( Q \), let \( C_*(Q; R) \) denote a chain complex computing group homology of \( Q \) with coefficients in \( R \). All \( R[G_g] \)-modules are flat, so the operation of tensoring over \( R[G_g] \) commutes with taking homology. We have
\[
H_i(\text{Mod}(\Sigma_{g,1}); A_g) \cong H_i(C_*(\text{Mod}(\Sigma_{g,1}, p); R) \otimes_{R[G_g]} A_g)
\]
\[
\cong H_i(\text{Mod}(\Sigma_{g,1}, p); R) \otimes_{R[G_g]} A_g
\]
\[
\cong (H_i(\text{Mod}(\Sigma_{g,1}, p); R) \otimes_R A_g)_{G_g}
\]
Let $D_i$ denote the generation degree of $H_i(\text{Mod}(\Sigma, p); R)$ and $R_i$ denote the relation degree. By Proposition 4.2, $H_i(\text{Mod}(\Sigma, p); R) \otimes_R A_g$ has generation degree $\leq D_i + d$ and relation degree $\leq \max(D_i + r, R_i + d)$. By Proposition 2.24, $(H_i(\text{Mod}(\Sigma, p, 1, p); R) \otimes_R A_g)_{G_g} \cong (H_i(\text{Mod}(\Sigma, 1, p, 1, p); R) \otimes_R A_g)_{G_{g+1}}$ for $g \geq \max(D_i + d, D_i + r, R_i + d)$. The claim now follows from the isomorphism established in the first paragraph and the bounds on $D_i$ and $R_i$ from Theorem 3.5. □

Proof of Theorem F. The proof is identical to the proof of Theorem E except we use the bounds from Theorem 3.7. □
