Abstract. Environmental data are the key to defining and addressing water quality and quantity challenges at the catchment scale. Here, we present the first large-sample water quality data set for 1386 German catchments covering a large range of hydroclimatic, topographic, geologic, land use, and anthropogenic settings. QUADICA (water QUAlity, DIscharge and Catchment Attributes for large-sample studies in Germany) combines water quality with water quantity data, meteorological and nutrient forcing data, and catchment attributes. The data set comprises time series of riverine macronutrient concentrations (species of nitrogen, phosphorus, and organic carbon) and diffuse nitrogen forcing data (nitrogen surplus, atmospheric deposition, and fixation) at the catchment scale. Time series are generally aggregated to an annual basis; however, for 140 stations with long-term water quality and quantity data (more than 20 years), we additionally present monthly median discharge and nutrient concentrations, flow-normalized concentrations, and corresponding mean fluxes as outputs from Weighted Regressions on Time, Discharge, and Season (WRTDS). The catchment attributes include catchment nutrient inputs from point and diffuse sources and characteristics from topography, climate, land cover, lithology, and soils. This comprehensive, freely available data collection with a large spatial and temporal coverage can facilitate large-sample data-driven water quality assessments at the catchment scale as well as mechanistic modeling studies. QUADICA is available at https://doi.org/10.4211/hs.0ec5f43e43c349ff818a8d57699c0fe1 (Ebeling et al., 2022b) and https://doi.org/10.4211/hs.88254bd930d1466c85992a7de6947a4 (Ebeling et al., 2022a).

1 Introduction

Understanding hydrological and biogeochemical processes at various spatiotemporal scales is a major goal in catchment hydrology and is particularly relevant for robust predictions of water quantity and quality as well as adequate catchment management. Analyzing observations of the spatial and temporal dynamics of water quantity and quality at the catchment scale can give insights into relevant processes using a “pattern to process” approach (Sivapalan, 2006). Especially large-sample studies covering a wide range of catchments can advance our knowledge on patterns across scales, catchment similarity, and dominant processes, beyond a single catchment or local behavior (Addor et al., 2020; Kingston et al., 2020). Such studies allow for generalizable theories and applications by “balancing depth with breadth” and facilitate classifications, regionalization, and a better understanding of uncertainty in model predictions (Gupta et al., 2014). Thus, environmental data are the key for process understanding and hypothesis testing (Li et al., 2021). The col-
lection and availability of water quantity and quality data are steadily increasing with technological advances (Rode et al., 2016), but particularly harmonized and quality-controlled large-sample data sets of water quality and quantity along with catchment attributes are needed. These enable the identification and characterization of water quality and quantity response patterns and relationships with potential controls, facilitate hypothesis testing, and, thus, advance our understanding of the complex coupled hydrological and biogeochemical systems across larger samples and domains (Li et al., 2021).

In recent years, the application of large-sample studies has been advancing fast for (surface) water quantity studies investigating dominant processes and drivers of water flow characteristics. Gupta et al. (2014) provided an overview of such studies, with the first of them being published in the 1990s. These publications have been followed by a recent surge in studies documenting and analyzing large-sample hydrologic data sets, such as Newman et al. (2015), Kuentz et al. (2017), Do et al. (2017), Gnann et al. (2020), Tarasova et al. (2020), and Merz et al. (2020). These studies have identified catchment typologies, archetypal behavior, and underlying controls, such as discharge variability across Europe (Kuentz et al., 2017), catchments with similar runoff event types (Tarasova et al., 2020), or how catchment discharge attenuates and shifts climate seasonality (Gnann et al., 2020).

In contrast, large-sample studies for water quality are less common. Nevertheless, some recent large-sample water quality studies have provided a basis for enhancing our understanding of catchment functioning in terms of the mobilization, transport, and environmental fate of solutes and particulates as well as the generality of these functions. For example, Monteith et al. (2007) linked widespread positive trends in dissolved organic carbon (DOC) concentrations observed in Europe and North America with decreasing atmospheric sulfur and chloride deposition. Godsey et al. (2009, 2019) provided wide evidence that weathering-derived solutes are mostly exported chemostatically with low concentration variance. Basu et al. (2010) derived the hypothesis of chemostatic nutrient export resulting from homogenized sources due to the legacy of high inputs. More recently, Zarnetske et al. (2018) and Ebeling et al. (2021a) both provided evidence of widespread transport-limited DOC export from small to large catchments. However, several questions regarding general patterns, catchment similarities and typologies, and the underlying controls of the aforementioned factors remain open – for example, questions concerning the extent and recovery of nutrient legacy for both nitrogen (N) and phosphorous (P) (Chen et al., 2018), the extent of macronutrient interactions in differing landscape and anthropogenic settings as well as throughout the river network (Wollheim et al., 2018), and the impact of climate change on water quality trajectories in various catchments (Kaushal et al., 2018).

At the moment, large-sample studies are still hampered by limited availability (e.g., the number of stations, number of samples, and covered regions) and accessibility of spatially and temporally harmonized large-sample data collections (e.g., Addor et al., 2020), despite recent efforts to make consistent large-sample data sets of catchment hydrology for both water quantity and water quality in streams publicly available (e.g., Virro et al., 2021). Prominent examples of large-sample hydrological data sets including catchment attributes are the Catchment Attributes and MEmorology for Large-sample Studies (CAMELS) data sets, available for the USA (Addor et al., 2017), Chile (Alvarez-Garreton et al., 2018), Brazil (Chagas et al., 2020), Great Britain (Coxon et al., 2020), and Australia (Fowler et al., 2021). More recently, the multinational LArge-SaMple DAte for Hydrology and Environmental Sciences (LamaH; Klingler et al., 2021) initiative has provided hydrometeorological time series at an hourly resolution along with catchment attributes. For stream water quality, currently available large-sample data sets focus on water quality time series only but lack additional data. Recently, two global databases of surface water quality were published that combine data from several existing databases in homogenized and quality-checked form: the Surface Water Chemistry database (SwatChem; Rotteveel and Sterling, 2022), with a focus on variables relevant to acidification, and the Global River Water Quality Archive (GRQA; Virro et al., 2021), with a focus on macronutrients. Both include the global databases Global Freshwater Quality Database (GEMStat; UNEP, 2018) and the GLObal RIver CHemistry database (GLORICH; Hartmann et al., 2014) as well as the European Waterbase (EEA, 2020) database, although the spatiotemporal coverage of the data varies strongly. These are important recent advances towards open science in water quality research. However, to the authors’ knowledge, there is currently no combined, ready-to-use data set of metrics of water quality, quantity, catchment attributes, and forcing data (such as meteorological and nutrient inputs), which would allow for the investigation of water quality dynamics and their controls. Moreover, large-sample and cross-regional studies are especially challenging in countries like Germany, where data responsibility is scattered between federal states and data are often not freely available nor homogenized between water quantity and quality stations. Nevertheless, a few Germany-wide water quality studies on groundwater (Knoll et al., 2020) and surface water (Ebeling et al., 2021a) have recently been carried out.

The key objective here is to provide a spatially and temporally consistent comprehensive data set of joint water quality and quantity data, catchment attributes, and nutrient inputs for German catchments that is ready to use and freely available, supporting the open science philosophy and FAIR (findability, accessibility, interoperability, and reuse) data principles. In this “Water QUALity, DIscharge and Catchment Attributes for large-sample studies in Germany” (QUADICA) data set, we have complemented available data sets of catchment attributes with new data on water quality and water quantity. These data include delineated catchment bound-
aries, catchment responses in terms of macronutrient concentrations (species of N; P; and organic carbon, OC) and discharge \(Q\), forcing data in terms of meteorological and diffuse nitrogen inputs, and catchment attributes. We distinguish stations with a high data availability, which allows further estimation of daily concentrations and fluxes using a regression approach, and stations with lower availability, for which aggregated observed concentrations are reported. For water quality (Sect. 3.1) and water quantity (Sect. 3.2), we provide the following:

1. time series of annual medians of observed macronutrient concentrations (dissolved and total forms of N, P, and OC) and of observed discharge,

2. time series of monthly and annual medians of estimated daily macronutrient concentrations and flow-normalized concentrations as well as mean nutrient fluxes and medians of observed discharge for stations with high data availability,

3. monthly medians and the monthly 25th and 75th percentiles of observed concentrations and discharge over the whole time series.

Additionally, we provide time series of driving forces (Sect. 3.3 and 3.4) and catchment attributes (Sect. 4):

4. time series of observed monthly meteorological forcing variables as catchment averages (Sect. 3.3),

5. time series of estimated annual net diffuse nitrogen inputs to the catchments (Sect. 3.4),

6. average catchment attributes, i.e., topography, land cover, nutrient sources, lithology and soils, and hydroclimate (Sect. 4).

We envision that the QUADICA data set will directly enable large-sample assessments of mean concentrations and fluxes; their variability in terms of long-term trends, seasonality, and relationships to discharge; and their relationships to catchment attributes. We believe that the data set will allow a better understanding of catchment functioning and water management beyond regional scales and stimulate provisioning and analysis of further water quality data at national to continental scales.

### 2 Catchment selection and delineation

The station selection and catchment delineation have been presented in a previous study (Ebeling et al., 2021a) and data repository (Ebeling, 2021) and are now included in the new QUADICA data set. All data sets use the same unique identifier (OBJECTID) for the stations and corresponding catchments. The station selection is based on riverine water quality data assembled from the German federal state environmental authorities, who are responsible for the routine monitoring of water quality in Germany (Musolff et al., 2020; Musolff, 2020) and take grab samples at approximately monthly intervals.

The following preprocessing steps were applied for each station and compound separately: we removed duplicate, negative, and zero values and applied an outlier test for each time series (removing values above mean concentration and 4 times the standard deviation in logarithmic space, i.e., confidence level > 99.99% for lognormally distributed data). Finally, 1386 stations met the criteria concerning water quality data and catchment delineation (Fig. 1) as described in the following: in the first step, water quality data cover at least 3 years, include a minimum of 70 samples from 2000 to 2015 after preprocessing, and cover all seasons, i.e., seasonal coverage of at least 10% of the samples in each quarter considering all possible combinations of 3 consecutive months (criteria one to three as described in Ebeling et al., 2021a). These criteria should ensure that a representative amount of data is available. Stations fulfilling these water quality data criteria for nitrate (NO\(_3\)-N) or phosphate (PO\(_4\)-P) were preselected (i.e., 1692 stations). Other variables (e.g., total phosphorus, TP; total nitrogen, TN; and DOC) were not used in this initial step of station selection.

In the second step, we delineated the catchment area from topography for these preselected stations and verified them as described here. The topographic catchment boundaries were delineated based on a 100 m flow accumulation grid derived from a digital elevation model (DEM; resampled from 25 to 100 m using the average; EEA, 2013) using spatial analysis tools and a D8 flow direction type. The river network from the Rivers and Catchments of Europe – Catchment Characterisation Model (De Jager and Vogt, 2007) was used to burn by 10 m into the DEM before deriving the flow accumulation. The stations were snapped or manually moved towards the representative flow accumulation stream to define the catchment outlets (four points). The resulting topography-based catchment polygons were quality-controlled manually by a comparison to the real river network. In case of major deviations, a few manual adaptations of the burned river segments were done if they substantially improved the overlap without hindering neighboring catchment delineations. In case of insufficient spatial overlap that could not be improved, stations were discarded from the selection. This resulted in a final set of 1386 catchments. The DEM, flow direction, and flow accumulation raster used as well as the modified station locations and the river network are also provided in the data repository for further use.

The varying density of stations across Germany (Fig. 1a) has two main reasons: firstly, the provision of raw data varied with respect to the number of stations, number of samples per compound and station, and time series length among the federal states; secondly, the topographic delineation of catchment boundaries was more successful where the topography is more pronounced, giving less delineable catchments in northern Germany. The delineated catchment boundaries...
are provided with the data set and enable the user to develop further geoinformation routines (e.g., to extract characteristics from other geographic data sets).

3 Time series

For the 1386 delineated catchments, riverine concentration time series of nitrate (NO$_3$-N), mineral nitrogen (N$_{\text{min}}$), total nitrogen (TN), phosphate (PO$_4$-P), total phosphorus (TP), dissolved organic carbon (DOC), and total organic carbon (TOC) are provided (Table 1). They are supplemented by time series of discharge (where available) and forcing variables (meteorological drivers and diffuse N input). Due to limited data availability, not all variables can be provided for all stations.

3.1 Water quality time series

3.1.1 Annual median concentrations

Annual medians of concentration data are presented for time series of the 1386 stations fulfilling the water quality criteria (as done for the catchment selection criteria described in Sect. 2). To calculate summary statistics, we substituted concentration values below the detection limit (left-censored data) with half the detection limit.

The resulting data density distributions over time and the number of years covered by each variable show the highest data availability for TOC, PO$_4$-P, and NO$_3$-N in more recent years (Fig. 2). An overview of the time series statistics for each variable is given in Table 2, and time series are shown in Appendix A (Fig. A1). For NO$_3$-N concentrations, the number of stations with available data is 1339, and the median number of samples per station is 157. The earliest time series starts in 1954, but the median start across stations is in 1994. The median time series length is 19 years, and the maximum time series length is 61 years. For PO$_4$-P concentrations, the number of stations with available data is 1330, and the median number of samples per station is 152. The earliest time series starts in 1965, but the median start across stations is in 1993. The median time series length is 20 years, and the maximum time series length is 48 years. For TOC concentrations, the number of stations with available data is 1296, and the median number of samples per station is 139. The earliest time series starts in 1979, but the median start across stations is in 1999. The median time series length is 15 years, and the maximum time series length is 36 years. For all water quality variables, the median of the first year of the time series is in the 1990s, and the median number of samples per station and year is 12, indicating that grab samples were taken on a monthly basis on average. Note that the number of samples underlying the median values can differ between the different nutrient species so that the fraction of TN present as NO$_3$-N or TP present as PO$_4$-P may show inconsistencies for single stations (e.g., values above one).

3.1.2 Monthly median concentrations and mean fluxes for stations with high data availability

For the subset of stations with high data availability, a Weighted Regressions on Time, Discharge, and Season (WRTDS; Hirsch et al., 2010) analysis was applied using the “EGRET” R package (version 3.0.2; Hirsch and De Cicco, 2015). We refer to these stations as “WRTDS stations” for short. WRTDS represents long-term trends, seasonal components, and discharge-related variability in the water quality variables (Hirsch et al., 2010). The criteria for a WRTDS application were checked for each station and compound separately using the preprocessed data, as described in Sect. 2. The criteria were a time series of at least 20 years length, at least 150 samples of water quality, no data gaps larger than 20 % of the total time series length, and a complete time series of daily discharge (see also Sect. 3.2.2). The number of WRTDS stations varies between 44 for TN and 126 for PO$_4$-P (Table 3), and the fraction of stations with high data availability varies between 4.9 % for TOC and 11.7 % for TP.

For WRTDS stations, we provide the monthly and annual median estimated water quality and observed quantity data in addition to the annual observed data (see above). More specifically, we provide monthly and annual median concentration and flow-normalized concentration as well as mean flux estimates from the WRTDS model output and median observed discharge (see Sect. 3.2.2) if data are available for at least 80 % of the respective time frame. The median $R^2$ between WRTDS-modeled and observed concentrations varies between 0.44 for DOC and TOC and $0.75$ for TN (Table 3); overall, 69.3 % of the catchment and compound combinations have a median $R^2$ of at least 0.5. The median bias varies between $-1.4$ % for PO$_4$-P (negative values indicate overestimation) and $0.2$ % for NO$_3$-N (positive values indicate underestimation); overall, 51 % of the catchments have a bias below 1 %, and 95 % of the catchments have a bias below 5 %. An overview of the availability of WRTDS stations and model performance is given in Table 3 and shown in Fig. A2, their locations are shown in Fig. 1a, and their performance is provided in the data repository.

3.1.3 Monthly median concentrations over the time series

Next to annual and monthly time series, we provide long-term monthly medians over the complete time series of each station, enabling assessments of average seasonal variability. We also include the 25th and 75th percentiles to reflect the long-term variability in a given month. The provided data frame in QUADICA indicates the number of samples available for the corresponding month across the years, based on which representativeness can be assessed and quality criteria can be defined.
Figure 1. Map of (a) water quality stations, catchments, and elevation (EEA, 2013) and (b) map of land cover (EEA, 2016a). The colors in panel (a) distinguish between stations with (green) and without (yellow) discharge ($Q$) data and stations with high data availability of concentration and discharge (purple, WRTDS stations; for details, see Sect. 3.1). WRTDS refers to Weighted Regressions on Time, Discharge, and Season.

Figure 2. Heat map of (a) the number of stations with available annual medians over time and per variable and (b) the number of years covered by each station. $Q_{\text{grab}}$ refers to the median discharge ($Q$) from grab sample dates, and $Q_{\text{daily}}$ refers to median $Q$ from daily discharge (see Sect. 3.2.1 for details). For visualization purposes, in panel (a), station counts from 1954 are shown, omitting one concentration and a few $Q_{\text{daily}}$ records before 1954; in panel (b), counts up to 67 years are shown, omitting three longer $Q_{\text{daily}}$ records.
Table 1. Provided time series data as well as their basis (observed or estimated), aggregation type, temporal resolution, and source of original data, which was used to calculate the aggregated data provided here.

| Variable                | Section | Data basis | Temporal (Spatial) aggregation | Temporal resolution | Source                                      |
|------------------------|---------|------------|--------------------------------|---------------------|---------------------------------------------|
| Concentration of NO\textsubscript{3}-N, N\textsubscript{min}, TN, PO\textsubscript{4}-P, TP, DOC, and TOC | 3.1     | Observed   | Median                         | Annual              | Musolff et al. (2020); Musolff (2020)       |
|                        |         |            | Median daily using WRTDS       | Monthly             | Musolff et al. (2020); Musolff (2020)       |
|                        |         | Observed   | Long-term median               | Monthly             | Musolff et al. (2020); Musolff (2020)       |
| Discharge              | 3.2     | Observed   | Median                         | Annual              | Musolff et al. (2020); Musolff (2020)       |
|                        |         |            | Median                         | Monthly             | Musolff et al. (2020); Musolff (2020)       |
|                        |         | Observed   | Long-term median               | Monthly             | Musolff et al. (2020); Musolff (2020)       |
| Precipitation          | 3.3     | Observed gridded | Sum (Average)                  | Monthly             | E-OBS v18.0e, Cornes et al. (2018)          |
| Potential evapotranspiration | 3.3   | Estimated  | Sum (Average)                  | Monthly             | E-OBS v18.0e, Cornes et al. (2018)          |
| Mean air temperature   | 3.3     | Observed gridded | Average (Average)              | Monthly             | E-OBS v18.0e, Cornes et al. (2018)          |
| Diffuse N input as total | 3.4   | Estimated  | (Average)                      | Annual              | See Sect. 3.4                                |
| Diffuse N input from agricultural areas | 3.4   | Estimated  | (Average)                      | Annual              | See Sect. 3.4                                |

The abbreviations used in the table are as follows: nitrate (NO\textsubscript{3}-N); mineral nitrogen (N\textsubscript{min}); total nitrogen (TN); phosphate (PO\textsubscript{4}-P); total phosphorus (TP); dissolved organic carbon (DOC); total organic carbon (TOC); and Weighted Regressions on Time, Discharge, and Season.

3.2 Water quantity time series

For about 43 % of the water quality stations (n = 590), information on discharge is available (Fig. 1a) and is provided harmonized with the water quality data (i.e., at the annual and monthly resolution). The discharge information is a collection of data provided by the federal states along with the concentration data, either as daily discharge time series or for the times of grab sampling of water quality. Additionally, we integrated daily discharge data from 53 stations available from the Global Runoff Data Center (GRDC) to increase the number of stations with available discharge time series. We matched GRDC gauging stations to the existing water quality stations using a search radius of 500 m. For each match, we checked the consistency of river names and visually confirmed the locations. The corresponding GRDC station numbers are indicated in the metadata of the water quality and quantity data set (Musolff, 2020). For the original daily discharge data, the reader may refer to the regularly published and accessible data at the GRDC portal (https://portal.grdc.bafg.de, last access: 8 August 2022).

3.2.1 Annual median discharge

Annual median discharge is aggregated from available observed discharge data. For 324 water quality stations, a co-located Q station with a continuous daily Q record is available. However, the time series may include data gaps, and the time series of discharge and concentration data do not over-lap at all for nine of the co-located discharge stations. For an additional 266 stations, Q data were only available at the time that the grab samples were taken. This resulted in a set of 581 stations for which Q data were available on the sampling dates of concentration data. We extracted annual me-
Table 2. The number of stations with available data for the water quality compounds and discharge during grab sampling dates, the earliest and median start year of time series, the maximum and median time series length and covered years (i.e., years with available data), the median number of samples per stations and per station and year, and the number of outliers removed.

| Variable | Unit     | NO₃-N mg L⁻¹ | Nₗₘᵢₙ mg L⁻¹ | TN mg L⁻¹ | PO₄-P mg L⁻¹ | TP mg L⁻¹ | DOC mg L⁻¹ | TOC mg L⁻¹ | Q_{grab} m³ s⁻¹ | Q_{daily} m³ s⁻¹ |

| Maximum  | fraction of outliers per station (%) | 1.7 | 1.7 | 1.7 | 1.7 | 2.5 | 3.1 | 3.6 | – | – |

* Omitting one sample from 1900. The abbreviations used in the table are as follows: nitrate (NO₃-N), mineral nitrogen (Nₗₘᵢₙ), total nitrogen (TN), phosphate (PO₄-P), total phosphorus (TP), dissolved organic carbon (DOC), total organic carbon (TOC), the median discharge (Q) from grab sample dates (Q_{grab}), and the median Q from daily discharge (Q_{daily}).

Table 3. The number of stations with high data availability (WRTDS stations) for each compound and the median coefficient of determination for WRTDS models.

| Variable | Unit     | Total NO₃-N mg L⁻¹ | Total Nₗₘᵢₙ mg L⁻¹ | Total TN mg L⁻¹ | Total PO₄-P mg L⁻¹ | Total TP mg L⁻¹ | Total DOC mg L⁻¹ | Total TOC mg L⁻¹ |
|----------|----------|---------------------|---------------------|-----------------|-------------------|-----------------|-----------------|-----------------|
| Number   | of WRTDS stations | 140 | 125 | 97 | 44 | 126 | 122 | 61 | 64 |
| Median R² |          | 0.61 | 0.63 | 0.71 | 0.75 | 0.69 | 0.53 | 0.44 | 0.44 |
| Median bias (%) |          | −0.3 | 0.2 | 0.1 | 0.1 | −1.4 | −0.9 | −0.6 | −0.6 |

The abbreviations used in the table are as follows: nitrate (NO₃-N); mineral nitrogen (Nₗₘᵢₙ); total nitrogen (TN); phosphate (PO₄-P); total phosphorus (TP); dissolved organic carbon (DOC); total organic carbon (TOC); and Weighted Regressions on Time, Discharge, and Season (WRTDS).

dian discharge from both continuous daily data (Q_{daily}) and dates when the water quality sample was taken (Q_{grab}, with a median of 13 values per year; Table 2) for the water quality stations. The density distribution of stations with available annual discharge over time is shown in Fig. 2a. Similar to the concentration data, the data availability is higher in more recent years, with a maximum of 449 stations in 2010. The number of years covered is, however, higher compared with water quality data for several stations (Fig. 2b). For stations with available daily discharge data, both annual median values of the daily data and the data from grab sample days were compared (Fig. A3). Our results suggest that annual median values from grab sample days can be considered to be robust estimates of annual median discharge as they have a negligible bias (bias = −0.5 %) and low scatter around the 1 : 1 line (R² > 0.99). The time series are shown in Appendix A.
(Fig. A1). The data set additionally provides the number of samples used to calculate the medians as a measure of robustness.

3.2.2 Monthly median discharge

Monthly median discharge is provided for WRTDS stations. To fill gaps in the daily discharge time series of the 45 stations required for WRTDS models (see Sect. 3.1.2), we used simulated discharge from the mesoscale hydrological model (mHM) (Kumar et al., 2013; Samaniego et al., 2010; Zink et al., 2017) if the regression coefficient ($R^2$) between observed and simulated discharge for the station was greater than 0.6. Subsequently, modeled discharge was bias-corrected with piecewise linear regressions and used for gap filling (Ebeling et al., 2021b; Ehrhardt et al., 2021a). If modeled discharge was not available, small gaps (up to 7 days) were interpolated with fixed-interval smoothing using the “baytrends” R package (Murphy et al., 2019). Note that the gap-filled discharge time series are used for the WRTDS models only. This includes the monthly and annual discharge data provided with the WRTDS data tables (as described in Sect. 3.1.2).

3.2.3 Monthly median discharge over the time series

As for the water quality metrics (see Sect. 3.1.3), we provide long-term monthly median discharge and the 25th and 75th percentile over the whole time series, if available, for the station representing average discharge seasonality. The number of samples used for the calculation of medians is indicated as a measure of accuracy.

3.3 Meteorological time series

Meteorological time series are provided as spatial catchment averages at a monthly resolution. We used the daily gridded product of climate variables (precipitation and maximum, minimum, and average air temperature) from the “European Climate Assessment & Dataset” (ECA&D) project (E-OBS, v18.0e; Cornes et al., 2018). The advantage of a European data set is the coverage of transnational catchments, such as the Elbe or the Rhine. The data sets are available at a spatial resolution of 0.1° over the period from 1950 to 2018. The interpolation approach employed to create the gridded fields uses a stochastic technique based on Gaussian random field and involves several ground-based observation networks distributed across Europe (see Cornes et al., 2018, for more details). The daily fields of potential evapotranspiration are derived based on the method from Hargreaves and Samani (1985) at the same spatial resolution (0.1°) using the daily (maximum, minimum, and average) air temperature data sets. We then calculated the spatial averages of daily climate variables (precipitation, air temperature, and potential evapotranspiration) for all water quality stations, considering the corresponding (upstream) catchment area. Monthly estimates of total precipitation and potential evapotranspiration as well as average air temperatures were subsequently calculated for each study basin.

3.4 Time series of net N input from diffuse sources

For the period from 1950 to 2015, we provide time series of catchment-scale N surplus (i.e., the net diffuse N input), which is the sum of N inputs minus the sum of N outputs from harvesting. At the catchment scale, the N surplus is the sum of N surplus from agricultural areas ($N_{agri}$; kg yr$^{-1}$ ha$^{-1}$) and nonagricultural areas ($N_{nonagri}$; kg yr$^{-1}$ ha$^{-1}$) normalized to the catchment area. For transboundary catchments with area outside of Germany, N surplus is normalized to the German part only. For nonagricultural areas, the N surplus is composed of atmospheric N deposition and biological N fixation. For agricultural areas, the N surplus includes additional N inputs (i.e., mineral fertilizer and manure applications) and N outputs from harvesting.

For agricultural land, the N surplus data stem from two data sets: one at the state level provided for the period from 1950 to 1998 (Behrendt et al., 2003, which builds on Bach and Frede, 1998, and Behrendt et al., 2000) and one at the county level provided for the period from 1995 to 2015 (Häußermann et al., 2019). To create a consistent long-term data set (1950–2015), we harmonized the county- and state-level data sets based on the overlapping years (1995–1998) and downscaled the state-level data to the county level for the period from 1950 to 1994. Specifically, we bias-corrected the state-level data of Behrendt et al. (2003) using proportions, as they commonly underestimated the values provided by Häußermann et al. (2019) for the period from 1995 to 1998. To downscale the bias-corrected state-level N surplus (1950–1994) to the county level, we used a linear regression between the county and state totals for the period from 1995 to 2015 (data from Häußermann et al., 2019). As data for city states (Berlin, Bremen, and Hamburg) are not provided in the state-level data set, we used the average value from 1995 to 1998 for the period from 1950 to 1994 under the assumption that the error is acceptable considering the small agricultural areas. The N surplus data comprise values for 5 of the 11 agricultural land classes in the CORINE (Coordination of Information on the Environment) Land Cover (CLC) inventory (EEA, 2016a): nonirrigated arable land, vineyards, fruit trees and berry plantations, pastures, and complex cultivation patterns. The data include N inputs from applications of fertilizers in mineral and organic forms, from seeds and planting material (county-level data only), from N deposition, and from biological N fixation as well as N outputs from harvested crops. To upscale agricultural N surplus from the county level to the catchment level, we used the fraction of agricultural area provided by CLC and a scaling factor. As CLC overestimates agricultural areas compared with the census data at the county level (Bach et al., 2006), we scaled the agricultural areas from CLC in each county by the mean ratio
between the agricultural area from census data (Häußermann et al., 2019) and the CLC maps (years 2000, 2006, and 2012; median ratio of 1.24 across counties).

For nonagricultural land (CLC forest, water bodies, wetlands, and grassland classes) and the remaining agricultural land CLC classes not covered by the N surplus data described above (e.g., permanently irrigated land), we used the atmospheric N deposition data from the Meteorological Synthesizing Centre – West (MSC-W) of the European Monitoring and Evaluation Programme (EMEP; Simpson et al., 2012). The EMEP database uses a chemical transport model to generate a consistent gridded field of Europe-wide wet and dry as well as oxidized and reduced atmospheric N deposition (Simpson et al., 2012). The model assimilates varying levels of observational information on different atmospheric chemicals (e.g., Bartnicki and Benedictow, 2017; Bartnicki and Fagerli, 2006). The data were available for the period from 1980 to 1995 with 5-year time steps, which we linearly interpolated to obtain an annual time series, and with annual time steps for the period from 1995 to 2015. For the data before 1980, we assumed constant values from 1980 due to missing information. Deposition on urban sealed surfaces was neglected, as we assume that this component is collected by the sewer system and transported to the wastewater treatment plants. Thus, we assume it is not a diffuse N source but part of the point sources (Sect. 4.3). In contrast, deposition on urban grassland, like public parks, was considered. To account for the overestimated area of the five agricultural CLC classes in the agricultural N surplus data (see above), we added the corresponding missing fraction proportionally to the remaining land cover classes. We estimated terrestrial biological N fixation by plants for nonagricultural, vegetated areas using land-use-specific rates provided by Cleveland et al. (1999) and Van Meter et al. (2017).

The catchment-scale N surplus time series were calculated by intersecting the two N surplus components (\(N_{\text{agri}}\) and \(N_{\text{nonagri}}\)) with the respective land use and catchment area components. As the N surplus data were only available within Germany, data from transboundary catchments (e.g., the main stretch of the Elbe or Rhine rivers) need to be used cautiously, with higher uncertainty for catchments with a higher fraction of the catchment area outside of Germany (Sect. 4.3). Figure 3 shows the resulting N input time series of all catchments. The majority of N input stems from agriculture, with a median of 64 % of the total catchment N surplus stemming from \(N_{\text{agri}}\) across all catchments (averages between 1950 and 2015). The agricultural N surplus (\(N_{\text{agri}}\)) and its fraction per catchment were highest during the 1980s, with a median across catchments of 52 kg ha\(^{-1}\) yr\(^{-1}\) and 76 % (average between 1980 and 1989), respectively. The highest mean agricultural N surplus and annual fraction across all catchments were reached in 1988, with respective values of 60.7 kg ha\(^{-1}\) yr\(^{-1}\) and 74 %, although these values were already above 50 kg ha\(^{-1}\) yr\(^{-1}\) and 70 % from 1976 to 1989. For the total N surplus, the mean annual values across catchments were above 70 kg ha\(^{-1}\) yr\(^{-1}\) during the same period (1976–1989), although values were above 50 kg ha\(^{-1}\) yr\(^{-1}\) from 1969, and the maximum of 76.7 kg ha\(^{-1}\) yr\(^{-1}\) occurred in 1980.

### 4 Catchment attributes

The provided catchment attributes characterize the catchments in terms of topography, land cover, nutrient sources, lithology and soils, and hydroclimate. The attributes were chosen with a focus on macronutrient sources and transport in line with the data set. Figure 4 shows the spatial distribution of a set of selected catchment attributes. All attributes, their variable names, original data sources, and methods are listed in Appendix B (Table B1) and the data repository (Ebeling et al., 2022a). This repository of catchment attributes is a composite of attributes from two existing repositories (Ebeling and Dupas, 2021; Ebeling, 2021).

#### 4.1 Location and topography

Catchment size was calculated from the delineated catchment boundaries described in Sect. 2. Catchment size ranges from 0.9 to 123 012 km\(^2\), with a median of 171.2 km\(^2\), a 25th percentile of 53.6, and a 75th percentile of 634.4 km\(^2\). Additionally, the fraction of the catchment area lying within German borders was calculated (\(f_{\text{AreaGer}}\)). Mean and median catchment elevation and topographic slope were extracted from the DEM with a 100 m resolution (see also Sect. 2; EEA, 2013). A 100 m grid of the topographic wetness index (TWI) was calculated from the DEM by relating the upstream area (from flow accumulation) to the local slope at each grid cell, following Beven and Kirkby (1979). For each catchment, we extracted mean, median, and 90th percentile TWI values. The 90th percentile has been shown to be a proxy for the abundance of riparian wetlands in a catchment (Musolf et al., 2018). Drainage density, defined as the length of surface waters per area, closely relates to topography. Drainage density was calculated and provided in two ways: as the catchment average of the gridded drainage density (cell size 0.012\(^2\)) provided in the Hydrologischer Atlas Deutschland (BMU, 2000) and as the river length from EU-Hydro River Network Database (EEA, 2019) within the catchment divided by its area. For the latter, the level of detail was too coarse to yield plausible values for all catchments, which is why values are missing for 27 of the smaller catchments. However, the EU-Hydro River Network Database provides further stream attributes such as the Strahler order.

#### 4.2 Land cover and population density

The fractions of land cover classes were calculated from the level 1 classification of the CLC data set for 2012 (artificial, agricultural, forested land, wetland, and surface water cover) (EEA, 2016a). For a finer distinction within these overall
Figure 3. Time series of annual N surplus for all catchments for the different N surplus components: N surplus for nonagricultural areas (a), N surplus for agricultural areas (b), and total N surplus for both nonagricultural and agricultural areas (c). Box plots represent the distribution of the annual N surplus as averages of the German catchment area across all catchments showing summary statistics (median, quartiles, and quartiles ±1.5 times the interquartile range) and individual points outside these ranges. The black lines represent the mean annual values for each N surplus component across the catchments.

classes, fractions of land cover classes were additionally calculated from level 2 data. Note that there can be an overestimation of agricultural areas from these CLC land cover classes when compared with census data as described by Bach et al. (2006) and considered for N surplus time series (Sect. 3.4). Nevertheless, we expect that the relative distribution of agricultural fractions among the catchments is well captured. The mean catchment population density was calculated from the Gridded Population of the World data set (CIESIN, 2017) for 2010.

4.3 Nutrient sources

The input from point sources is calculated as the sum of the N and P load from wastewater treatment plants (WWTPs) with more than 2000 population equivalents (PEs) from the database of the European Environment Agency (EEA, 2017) and data collected from 13 German federal states covering smaller WWTPs (PE < 2000) within Germany (Büttner, 2020). One PE is defined as the organic biodegradable load having a 5-day biochemical oxygen demand (BOD5) of 60 g of oxygen per day (EC, 1991a). As a second data source, we calculated catchment averages of the European domestic waste emissions database (Vigiak et al., 2019, 2020) for N, P, and BOD5 inputs from point sources. The average N, P, and BOD5 input per person was estimated using the point source input divided by the number of inhabitants according to the population density. The advantage of these European data is the consistency for an extended transnational data set – for example, it is available for German and French catchments (Ebeling and Dupas, 2021).

The net N input from diffuse sources was determined as temporal averages of diffuse N surplus time series (Sect. 3.4) for different periods, representing the main sampling period with historic inputs (1980–2015) and the current period (2000–2015). We also calculated averages for the periods before (1971–1990) and after (1991–2015) the EU 91/676/EEC Nitrates Directive (EC, 1991b) as well as the difference between them, which was used as a characteristic of net input change. Note that the N surplus data used only cover Germany, but catchments can be transnational. The uncertainty increases for larger areas outside of Germany, for which f_AreaGer can be used as a measure. To estimate source apportionment between point and diffuse N sources, we calculated the fraction of catchment point source N loads (N_WW_frac) from total catchment N input as the sum of catchment point source N loads from domestic waste emissions (N_T_YKM2) and N surplus (here using Nsurp80_15 for the period from 1980 to 2015) on average:

\[ N_{\text{WW}_\text{frac}} = \frac{N_{\text{T\_YKM2}}}{N_{\text{T\_YKM2}} + N_{\text{surp80\_15}}} \]

We defined horizontal and vertical source heterogeneity in catchments to quantify the spatial distribution of diffuse nutrient sources with a focus on NO3-N (Ebeling et al., 2021a). The horizontal source heterogeneity describes the distribution of agricultural land use in a catchment in relation to the stream network. We used the horizontal flow distance of the 100 m DEM (EEA, 2013; Sect. 2) to the EU-Hydro River Network Database (EEA, 2019) and a highly resolved land use map of 2015 provided by Pflugmacher et al. (2018). We divided the grid into classes of flow distance to stream with 400 m steps. Subsequently, we fitted a linear regression to
Figure 4. Maps of selected catchment attributes. Each dot represents one station, and the color represents the attribute of the corresponding catchment. Colors are according to the quartiles of the data distribution of each attribute. The attributes shown are as follows: dem.mean – average elevation [m], twi.90p – 90th percentile of the topographic wetness index [–], P_mm – mean annual precipitation [mm yr$^{-1}$], AI – aridity index [–], T_mean – mean air temperature [$^\circ$C], specQobs – specific annual discharge [mm yr$^{-1}$], f_sedim – fraction of sedimentary aquifer [–], f_sand – fraction of sandy soils [–], pdens – population density [inhabitants km$^{-2}$], het_v – vertical concentration heterogeneity [–], Nsurp80_15 – mean N surplus from 1980 to 2015 [kg N ha$^{-1}$ yr$^{-1}$], and soilP.mean – phosphorus content in topsoil [mg kg$^{-1}$]. For more details on the attributes, the reader is referred to the text in Sect. 4 and Table B1.
catchment that has a vertical homogeneity in NO$_3$-N concentrations, whereas a ratio above 1 describes stronger vertical concentration gradients.

### 4.4 Lithology and hydrogeology

To characterize the lithological and the hydrogeological settings of the catchments, we used the International Hydrogeological Map of Europe 1 : 1 500 000 (BGR and UNESCO, 2014). For the lithological settings, we derived the fraction of area covered by calcareous rocks, calcareous rocks and sediments, magmatic rocks, metamorphic rocks, siliciclastic rocks, siliciclastic rocks and sediments, and sediments (based on level 4 lithology data). Additionally, we determined the fractions of the more aggregated lithological classes (from level 5 lithology), i.e., consolidated, partly consolidated, and unconsolidated rocks. Furthermore, we quantified the areal fraction of aquifer type in the catchment, differentiating between porous aquifers, fissured hard-rock aquifers (including karst), and locally aquiferous or non-aquiferous rocks. Finally, we extracted the catchment median estimate of depth to bedrock from the global map from Shangguan et al. (2017).

### 4.5 Soil properties

We calculated the fraction of the catchment covered by hydromorphic soils (Stagnosols, semiterrestrial, semi-subhydric, subhydric, and peat soils) from the German soil map (1 : 250 000; BGR, 2018). As this data source only covers Germany, data might not be reliable for transboundary catchments (see also Sect. 4.3). We also calculated the average fraction of sand, silt, and clay averaged across the soil horizons of the top 1 m based on the Harmonized World Soil Database (HWSD; v1.2) available as a 30 arcsec raster database (FAO/IAEA/ISRIC/ISSCAS/JRC, 2012). We first estimated vertically weighted soil textural properties from the original HWSD data provided for two soil layers (upper 30 and 30–100 cm). Next, we calculated the areal averages of respective properties considering the boundary (polygon) of each study catchment.

We estimated the porosity of soil profiles (thetaS) based on the pedotransfer function of Zacharias and Wessolek (2007) and the root zone plant-available water content (WaterRoots), which reflects the difference in water content between the field capacity and permanent wilting point. The field capacity is calculated based on a flux-based estimation approach proposed by Twarakavi et al. (2009) corresponding to a minimum drainage flux of 1 mm d$^{-1}$. The estimate of the permanent wilting point is derived using the van Genuchten (1980) model of the matric potential at $-1500$ kPa and the corresponding model parameters calculated from pedotransfer functions of Zacharias and Wessolek (2007). Similar to soil textural properties, for each of these soil hydraulic parameters (porosity, field capacity, and permanent wilting point), we calculated areal averages of the vertically weighted estimates for the upper 1 m of the soil profile for each study catchment. More details on this method of using pedotransfer functions and subsequent aggregations can be found in Livneh et al. (2015). Furthermore, we estimated average catchment soil chemistry of the topsoil (first 20 cm) for the year 2009 from the European soil chemistry map, which is based on the LUCAS (Land Use and Cover Area frame Survey) database (Ballabio et al., 2019). For this, we calculated the mean C/N ratio, nitrogen content, and phosphorus content from the maps for each catchment.

### 4.6 Hydroclimatic characteristics

Long-term average hydroclimatic characteristics were derived from the meteorological (Sect. 3.3) and discharge time series. All climatic characteristics were calculated for a period of 30 years from 1986 to 2015 based on the E-OBS data set from the ECA&D project (v18.0e; Cornes et al., 2018). First, we provide mean annual precipitation, mean annual potential evapotranspiration, mean annual air temperature, and the aridity index as the ratio between potential evapotranspiration and precipitation. The variability in precipitation is further characterized by the mean precipitation frequency and depth (Botter et al., 2013) as well as by two seasonality indices, i.e., the ratio between summer (June–August) and winter (December–February) precipitation ($P_{SIw}$) and the average difference between average daily precipitation within each month and within a year ($P_{SI}$).

The hydrologic properties were characterized from stations with observed daily discharge data (Sect. 3.2) for different time periods according to the available data and study purposes of the original data sets. For current properties, daily discharge data from November 1999 (hydrological year 2000) were used for calculations (309 stations). Additionally, the hydrologic characteristics calculated from daily discharge data starting in 1986 are provided (319 stations), which are possibly more relevant for studies with a long-term perspective. If there were only data before 1986, we used the available time period (four stations). The actual starting and ending dates of the time series finally used for calculations are provided to inform the user of the exact time periods (StartQobs and EndQobs or Q_StartDate and Q_EndDate, respectively, refer to Table B1). Provided average characteristics include mean, median, median summer (May–October), median winter (November–April), and specific discharge. For the variability in discharge, we provide the coefficient of variation, the base flow index (according to WMO, 2008), and the flashiness index based on flow percentiles (ratio of the 5th to the 95th percentile) as well as discharge seasonality in terms of the ratio between summer and winter median discharge and the runoff coefficient (discharging fraction of precipitation).
5 Limitations

The presented data set has several limitations. More than half of the stations do not have co-located gauging stations and the ones that do are not homogeneously distributed across Germany. Existing concentration time series would benefit from available discharge data, as this allows the characterization of concentration-discharge relationships as well as the estimation of daily concentration, flow-normalized concentration and flux data for stations with high data availability using the WRTDS method. Generally, modeled discharge from hydrological models such as mHM (Sect. 3.2.2) or estimated discharge using other (mechanistic or statistical modeling) techniques could serve to extend the data set of joint water quality and water quantity and overcome missing station matches or data gaps. Other limitations are linked to data policies by federal state authorities, which sometimes do not permit publication of raw quality and quantity data. However, we aimed to make a virtue of necessity by providing aggregated data and further ready-to-use metrics of water quality and quantity (e.g., annual median concentrations and monthly median concentrations over the whole time series). Attributes derived from exclusively national data sets, such as N surplus, underlie higher uncertainties in transboundary catchments, as data outside Germany are either not available or not consistent. Additionally, there is uncertainty in the attributes, stemming from the inherent uncertainties in the data sets and the catchment boundaries. However, the provided description and references of the methods and the underlying data sources should enable users to evaluate the reliability of each descriptor in the data set and exclude stations from the analyses if necessary. This also leaves room for further improvements and extensions when new data and knowledge become available. Besides a higher number of water quality stations, longer time series and more co-located discharge data, it would be especially interesting to add time series of nutrient inputs from point sources and from diffuse P sources, as well as information on tile drainage locations to the catchment attributes. For a better linkage of chemical water quality with ecological research questions, biological water quality variables such as chlorophyll-a concentrations would be highly valuable as well.

6 Data availability

The QUADICA data set presented here is freely available from two online repositories. The water quality and water quantity data described in this paper as well as the time series of meteorological and diffuse nitrogen input can be accessed at https://doi.org/10.4211/hs.0ec5f43e43c349ff818a8d576999c0fe1 (Ebeling et al., 2022b). The catchment data, including the catchment attributes, boundaries, and stations, have been published at https://doi.org/10.4211/hs.88254bd930d1466c85992a7dea6947a4 (Ebeling et al., 2022a). Due to license agreements, the raw concentration and raw discharge data provided by the German federal states cannot be made public, but they have been deposited in an institutional repository (Musolff et al., 2020). The metadata of the data and stations, however, are available from https://doi.org/10.4211/hs.a42addcb59a466a9aa56472dfe8721 (Musolff, 2020).

7 Conclusions

In this study, we provide a comprehensive homogenized data set with a large spatial and temporal coverage of both water quality and quantity observations along with catchment attributes. Specifically, the data set includes time series of water quality, co-located discharge, hydroclimatic data, and diffuse nitrogen inputs as well as catchment boundaries and more than 100 catchment attributes for 1386 German catchments. The presented QUADICA (water QUAlity, Discharge and Catchment Attributes for large-sample studies in Germany) data set offers the opportunity to identify spatial and temporal patterns of water quality along with water quantity. This allows one to formulate and test hypotheses on underlying processes by linking observed responses to the driving forces and catchment attributes. QUADICA also opens up opportunities to calibrate and validate water and solute transport models at the single- and multiple-catchment scales as well as at the national scale. Consequently, the data set has the potential to advance our understanding of water quality processes across scales. More specifically, the data can be used to examine various spatiotemporal water quality patterns such as average concentrations, trends, and average seasonality. For stations with high data availability, analyses can be extended to trajectories of seasonality, flow-normalized concentrations, and mass fluxes. The patterns can be investigated for the three different macronutrients, nitrogen, phosphorus, and organic carbon; their species; and for nutrient ratios. In addition, interactions between the nutrients and their spatiotemporal patterns can be assessed. In the context of comparative large-sample hydrology (e.g., Gupta et al., 2014), the spatiotemporal water quality patterns can be linked to catchment attributes to identify underlying processes. This can, for example, support quantification of the impact of human disturbances on nutrient cycles and their interactions with natural controls. Some studies have recently investigated spatiotemporal patterns and underlying controls in large-sample approaches using parts of the provided data set. For example, Ebeling et al. (2021a) assessed average nutrient concentrations and export dynamics, Ebeling et al. (2021b) evaluated long-term trajectories of nitrate seasonality, Ehrhardt et al. (2021b) quantified nitrogen legacies using nitrogen input and export time series, and Yang et al. (2021) modeled the impact of phosphorus inputs on stream network algae growth. These assessments and the derived hypotheses can be further explored and extended with...
the provided data to increase our knowledge on catchment functioning.

Furthermore, the provided data can be merged with other water quality and quantity data sets— for example, to enable assessments across transnational scales and an even larger variability in catchment attributes. Here, we hope to stimulate other researchers or environmental authorities to provide similar data sets of joint water quality and quantity data to make the wealth of spatiotemporal water quality data available, including long-term data that have been collected during research projects and regular monitoring activities, such as for the 2000/60/EC EU Water Framework Directive (EC, 2000). Therefore, we call for joint efforts to further increase opportunities for catchment-scale water quality assessments and modeling activities on regional, transnational, and even continental scales.
Figure A1. Time series of annual median concentrations and discharge observed at the 1386 water quality stations during grab sampling, as shown in Table 1 and Fig. 1 and described in Sect. 3.1. Note that, for visualization purposes, values before 1954 and values > 40 mg L$^{-1}$ for N species (i.e., five NO$_3$-N, seven N$_{\text{min}}$, and zero TN values) are not shown.
Figure A2. Distribution of the performance of WRTDS models by compound based on the coefficient of determination $R^2$ (a) and bias (b). Boxes highlight the median and quartiles of each distribution, and points display the performance values of single catchments. Note that, for visualization purposes, one bias value > 0.4 is not shown for TOC.

Figure A3. Comparison of annual medians from continuous daily discharge ($Q_{\text{daily}}$) and discharge at the dates grab samples were taken ($Q_{\text{grab}}$). Colors represent different catchments.
Table B1. Catchment attributes, associated methods, and original data sources used for calculating the attributes (Ebeling et al., 2022a). This collection of catchment attributes is merged and adapted from existing repositories (Ebeling, 2021; Ebeling and Dupas, 2021) and the related publications (Ebeling et al., 2021a, b). For more details, the reader is referred to Sect. 4.

| Category      | Variable | Unit     | Description and method                                                                 | Data source |
|---------------|----------|----------|----------------------------------------------------------------------------------------|-------------|
| General       | OBJECTID | –        | Unique identifier                                                                      |             |
| Station       | –        |          | Station name                                                                           |             |
| Area_km2      |          | km\(^2\) | Catchment area                                                                         |             |
| f_AreaGer     | –        |          | Fraction of catchment area within Germany                                             |             |
| Topography    | dem.mean | m.a.m.s.l.| Mean elevation of catchment, from the DEM rescaled from a 25 to 100 m resolution using the average | EEA (2013) |
|               | dem.median | m.a.m.s.l.| Median elevation of catchment, from the DEM rescaled from a 25 to 100 m resolution using the average | EEA (2013) |
|               | slo.mean | °        | Mean topographic slope of catchment, from the DEM (100 m resolution)                  | EEA (2013) |
|               | slo.median | °        | Median topographic slope of catchment, from the DEM (100 m resolution)                | EEA (2013) |
|               | twi.mean | –        | Mean topographic wetness index (TWI; Beven and Kirkby, 1979)                           | EEA (2013) |
|               | twi.med | –        | Median topographic wetness index (TWI; Beven and Kirkby, 1979)                         | EEA (2013) |
|               | twi.90p | –        | The 90th percentile of the TWI as a proxy for riparian wetlands (following Musolff et al., 2018) | EEA (2013) |
|               | ddhad    | km\(^{-1}\) | Average drainage density of the catchment. Gridded drainage density is provided as the length of surface waters (rivers and lakes) per area from a 75 km\(^2\) circular area centered around each cell | BMU (2000) |
|               | DrainDens | km\(^{-1}\) | Average drainage density of the catchment, calculated from the EU-Hydro River Network Database and intersection with catchment polygons (contains several implausible values, and values are often overly small due to the coarser resolution of the river network) | EEA (2019) |
| Land cover    | f_artif  | –        | Fraction of artificial land cover                                                     | EEA (2016a) |
|               | f_agric  | –        | Fraction of agricultural land cover                                                  | EEA (2016a) |
|               | f_forest | –        | Fraction of forested land cover                                                      | EEA (2016a) |
|               | f_wetl   | –        | Fraction of wetland cover                                                            | EEA (2016a) |
|               | f_water  | –        | Fraction of surface water cover                                                      | EEA (2016a) |
|               | f_urban  | –        | Fraction of class 11, level 2 of the CORINE Land Cover data set                      | EEA (2016a) |
|               | f_industry | –        | Fraction of class 12, level 2 of the CORINE Land Cover data set                     | EEA (2016a) |
| Category   | Variable   | Unit          | Description and method                                                                 | Data source |
|------------|------------|---------------|----------------------------------------------------------------------------------------|-------------|
|            | f_mine     | –             | Fraction of class 13, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_urban_veg| –             | Fraction of class 14, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_arable   | –             | Fraction of class 21, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_agri_perm| –             | Fraction of class 22, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_pastures  | –             | Fraction of class 23, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_agri_hetero | –     | Fraction of class 24, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_fores    | –             | Fraction of class 31, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_scrub    | –             | Fraction of class 32, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | f_open     | –             | Fraction of class 33, level 2 of the CORINE Land Cover data set                          | EEA (2016a) |
|            | pdens      | inhabitants km$^{-2}$ | Mean population density                                                               | CIESIN (2017) |
| Nutrient sources | Nsurp00_15 | kg N ha$^{-1}$ yr$^{-1}$ | Mean nitrogen (N) surplus per catchment during the sampling period (2000–2015) including the N surplus from agricultural land and atmospheric N deposition as well as biological N fixation from nonagricultural areas. Details on the N surplus data are given in Sect. 3.4. | Bach et al. (2006); Bach and Frede (1998); Bartnicki and Benedictow (2017); Bartnicki and Fagerli (2006); Behrendt et al. (1999); Cleveland et al. (1999); Häußermann et al. (2019); Van Meter et al. (2017) |
|            | Nsurp91_15 | kg N ha$^{-1}$ yr$^{-1}$ | Mean N surplus per catchment from 1991 to 2015 (after the 91/676/EEC Nitrates Directive was introduced) | See Nsurp00_15 |
|            | Nsurp80_15 | kg N ha$^{-1}$ yr$^{-1}$ | Mean N surplus per catchment from 1980 to 2015 (main sampling period)                 | See Nsurp00_15 |
|            | Nsurp71_90 | kg N ha$^{-1}$ yr$^{-1}$ | Mean N surplus per catchment from 1971 to 1990 (historic (legacy) inputs)            | See Nsurp00_15 |
|            | dNsurp71_91 | kg N ha$^{-1}$ yr$^{-1}$ | Change in mean N surplus between the periods from 1971 to 1990 and from 1991 to 2015, i.e., dNsurp71_91 = Nsurp71_90 – Nsurp91_15 | See Nsurp00_15 |
|            | N_WW       | kg N ha$^{-1}$ yr$^{-1}$ | Sum of N input from point sources including wastewater treatment plants (WWTPs) > 2000 person equivalents from the database of the European Environment Agency covering areas beyond Germany and data collected from 13 federal German states covering smaller WWTPs within Germany | Büttner (2020) |
| Category | Variable | Unit | Description and method | Data source |
|----------|----------|------|------------------------|-------------|
|          | P_WW     | kg P ha$^{-1}$ yr$^{-1}$ | Sum of P input from WWTPs analogous to N_WW | Büttner (2020) |
|          | N_T_YKM2 | t N km$^{-2}$ yr$^{-1}$ | Mean N input from point sources summing all N emission values provided in the EU domestic waste emissions database | Vigiak et al. (2019, 2020) |
|          | P_T_YKM2 | t P km$^{-2}$ yr$^{-1}$ | Mean P input from point sources summing all P emission values provided in the EU domestic waste emissions database | Vigiak et al. (2019, 2020) |
|          | BOD_T_YKM2 | t O km$^{-2}$ yr$^{-1}$ | Mean 5-day biochemical oxygen demand (BOD) input from point sources summing all BOD emission values provided in the EU domestic waste emissions database | Vigiak et al. (2019, 2020) |
|          | N_T_YEW  | t N inhabitant$^{-1}$ yr$^{-1}$ | Calculated N input per person (from EU domestic waste emissions database): $N_{T,YEW} = N_{T,YKM2}/n_{EW} \cdot \text{Area}_{km^2}$ | Vigiak et al. (2019, 2020) |
|          | P_T_YEW  | t P inhabitant$^{-1}$ yr$^{-1}$ | Calculated P input per person (from EU domestic waste emissions database): $P_{T,YEW} = P_{T,YKM2}/n_{EW} \cdot \text{Area}_{km^2}$ | Vigiak et al. (2019, 2020) |
|          | nEW      | –     | Calculated number of inhabitants: $n_{EW} = \text{pdens} \cdot \text{Area}_{km^2}$ | CIESIN (2017) |
|          | n_UWWTP  | –     | Number of point sources from the European WWTP database | EEA (2017) |
|          | N_WW_frac| –     | Fraction of point source loads from total N input loads: $N_{W,WW} = N_{T,YKM2} / (N_{T,YKM2} + N_{surp80_15})$ | Source areas based on Pflugmacher et al. (2018) |
|          | f_sarea  | –     | Fraction of source area in the catchment. Source areas were defined as seasonal and perennial cropland and grassland land cover classes using a highly resolved land use map (Pflugmacher et al., 2018) | Source areas based on Pflugmacher et al. (2018) |
|          | het_h    | m$^{-1}$ | Slope of relative frequency of source areas in classes of flow distances to stream as a proxy for horizontal source heterogeneity. For details, the reader is referred to Ebeling et al. (2021a) | Source areas based on Pflugmacher et al. (2018) |
|          | R2_het_h | –     | Coefficient of determination of horizontal source heterogeneity het_h | Source areas based on Pflugmacher et al. (2018) |
|          | sdist_mean | m     | Mean lateral flow distance of source areas to stream. For details, the reader is referred to Ebeling et al. (2021a) | Source areas based on Pflugmacher et al. (2018) |
|          | het_v    | –     | Mean ratio between potential seepage and groundwater NO$3$-N concentrations as proxy for vertical concentration heterogeneity. For details, the reader is referred to Ebeling et al. (2021a) | Knoll et al. (2020) |
Table B1. Continued.

| Category              | Variable   | Unit | Description and method                                                                 | Data source                  |
|-----------------------|------------|------|----------------------------------------------------------------------------------------|-------------------------------|
| Lithology and soils   | f_calc     | –    | Fraction of calcareous rocks (lithology level 4)                                         | BGR and UNESCO (2014)         |
|                       | f_calc_sed | –    | Fraction of calcareous rocks and sediments (lithology level 4, coarse and fine sediments aggregated) | BGR and UNESCO (2014)         |
|                       | f_magma    | –    | Fraction of magmatic rocks (lithology level 4)                                           | BGR and UNESCO (2014)         |
|                       | f_metam    | –    | Fraction of metamorphic rocks (lithology level 4)                                        | BGR and UNESCO (2014)         |
|                       | f_sedim    | –    | Fraction of sedimentary aquifer (lithology level 4, coarse and fine sediments aggregated) | BGR and UNESCO (2014)         |
|                       | f_silic    | –    | Fraction of siliciclastic rocks (lithology level 4)                                      | BGR and UNESCO (2014)         |
|                       | f_sili_sed | –    | Fraction of siliciclastic rocks and sediments (lithology level 4, coarse and fine sediments aggregated) | BGR and UNESCO (2014)         |
|                       | f_consol   | –    | Fraction of consolidated rocks (lithology Level 5)                                      | BGR and UNESCO (2014)         |
|                       | f_part_consol | – | Fraction of partly consolidated rocks (lithology level 5)                              | BGR and UNESCO (2014)         |
|                       | f_unconsol | –    | Fraction of unconsolidated rocks (lithology level 5)                                     | BGR and UNESCO (2014)         |
|                       | f_porous   | –    | Fraction of porous aquifer (code 1 and 2 of aquifer type)                               | BGR and UNESCO (2014)         |
|                       | f_porous1  | –    | Fraction of porous aquifer (code 1 of aquifer type)                                     | BGR and UNESCO (2014)         |
|                       | f_porous2  | –    | Fraction of porous aquifer (code 2 of aquifer type)                                     | BGR and UNESCO (2014)         |
|                       | f_fissured | –    | Fraction of fissured aquifer (code 3 and 4 of aquifer type)                             | BGR and UNESCO (2014)         |
|                       | f_fiss1    | –    | Fraction of fissured aquifer (code 3 of aquifer type)                                   | BGR and UNESCO (2014)         |
|                       | f_fiss2    | –    | Fraction of fissured aquifer (code 4 of aquifer type)                                   | BGR and UNESCO (2014)         |
|                       | f_hard     | –    | Fraction of locally aquiferous and nonaquiferous aquifer (code 5 and 6 of aquifer type) | BGR and UNESCO (2014)         |
|                       | f_hard1    | –    | Fraction of locally aquiferous rocks (code 5 of aquifer type)                           | BGR and UNESCO (2014)         |
|                       | f_hard2    | –    | Fraction of non-aquiferous rocks (code 6 of aquifer type)                               | BGR and UNESCO (2014)         |
|                       | f_inwater  | –    | Fraction of inland water (code 200 of aquifer type)                                     | BGR and UNESCO (2014)         |
|                       | f_ice      | –    | Fraction of snow or ice field (code 300 of aquifer type)                                | BGR and UNESCO (2014)         |
Table B1. Continued.

| Category | Variable     | Unit | Description and method                                                                 | Data source                                                                 |
|----------|--------------|------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
|          | dtb.median   | cm   | Median depth to bedrock in the catchment                                                 | Shangguan et al. (2017)                                                   |
|          | f_gwsoils    | –    | Fraction of water-impacted soils in the catchment (from 1: 250000 soil map), including  | BGR (2018)                                                                |
|          |              |      | Stagnosols, semiterrestrial, semi-subhydric, subhydric, and moor soils                   |                                                                            |
|          | f_sand       | –    | Mean fraction of sand in soil horizons of the top 100 cm                                | FAO/IIASA/ISRIC/ISSCAS/JRC (2012)                                         |
|          | f_silt       | –    | Mean fraction of silt in soil horizons of the top 100 cm                                |                                                                            |
|          | f_clay       | –    | Mean fraction of clay in soil horizons of the top 100 cm                                |                                                                            |
|          | f_clay_agri  | –    | Mean fraction of clay in soil horizons of the top 100 cm for agricultural land use (class | FAO/IIASA/ISRIC/ISSCAS/JRC (2012); EEA (2016a)                           |
|          |              |      | 2, level 1 CORINE; see f_clay and f_agric)                                               |                                                                            |
|          | WaterRoots   | mm   | Mean available water content in the root zone from pedotransfer functions                | Livneh et al. (2015); Samaniego et al. (2010); Zink et al. (2017)         |
|          | thetaS       | –    | Mean porosity in catchment from pedotransfer functions                                   |                                                                            |
|          | soilN.mean   | g kg\(^{-1}\) | Mean topsoil N in catchment                                                           | Ballabio et al. (2019)                                                   |
|          | soilP.mean   | mg kg\(^{-1}\) | Mean topsoil P in catchment                                                            | Ballabio et al. (2019)                                                   |
|          | soilCN.mean  | –    | Mean topsoil C/N ratio in catchment                                                     | Ballabio et al. (2019)                                                   |
| Hydrology| StartQobs    | YYYY-MM-DD | Starting date of \(Q\) time series used for calculating hydrological indices (1999-11-01 or start of time series) |                                                                            |
|          | EndQobs      | YYYY-MM-DD | End date of \(Q\) time series used for calculating hydrological indices                 |                                                                            |
|          | meanQobs     | \(m^3 s^{-1}\) | Mean discharge (period from StartQobs to EndQobs)                                        | Musolff (2020); Musolff et al. (2020)                                    |
|          | medQobs      | \(m^3 s^{-1}\) | Median discharge (period from StartQobs to EndQobs)                                      | Musolff (2020); Musolff et al. (2020)                                    |
|          | specQobs     | mm yr\(^{-1}\) | Mean annual specific discharge (period from StartQobs to EndQobs)                       | Musolff (2020); Musolff et al. (2020)                                    |
|          | CVQobs       | –    | Coefficient of variation of time series of daily \(Q\) (period from StartQobs to EndQobs) | Musolff (2020); Musolff et al. (2020)                                    |
|          | medSuQobs    | \(m^3 s^{-1}\) | Median summer discharge (months May–October; period from StartQobs to EndQobs)           | Musolff (2020); Musolff et al. (2020)                                    |
|          | medWiQobs    | \(m^3 s^{-1}\) | Median winter discharge (months November–April; period from StartQobs to EndQobs)       | Musolff (2020); Musolff et al. (2020)                                    |
|          | seasRQobs    | –    | Seasonality index of \(Q\), as a ratio between median summer and median winter \(Q\) (period from StartQobs to EndQobs) | Musolff (2020); Musolff et al. (2020)                                    |
### Table B1. Continued.

| Category | Variable | Unit | Description and method | Data source |
|----------|----------|------|------------------------|-------------|
|          | BFIQobs  | –    | Base flow index calculated according to WMO (2008) with the “lfstat” package (version 0.9.4) in R (period from StartQobs to EndQobs) | Musolff (2020); Musolff et al. (2020) |
|          | flashQobs| –    | Flashiness index of $Q$ as the ratio between the 5th percentile and the 95th percentile of the $Q$ time series (period from StartQobs to EndQobs) | Musolff (2020); Musolff et al. (2020) |
|          | RCQobs   | –    | Runoff coefficient (fraction of mean annual precipitation discharging as specific discharge, specQobs/P_mm) (period from StartQobs to EndQobs) | Musolff (2020); Musolff et al. (2020) |
|          | Q_StartDate | YYYY-MM-DD | Starting date of $Q$ time series used for calculating hydrological indices (from 1986, if possible, and using at least 3 years of data; in few cases, only earlier data were available) | |
|          | Q_EndDate | YYYY-MM-DD | End date of $Q$ time series used for calculating hydrological indices (as available) | |
|          | Q_mean   | m$^3$s$^{-1}$ | Mean discharge (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | Q_median | m$^3$s$^{-1}$ | Median discharge (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | Q_spec   | mm yr$^{-1}$ | Mean annual specific discharge (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | Q_CVQ    | –    | Coefficient of variation of time series of daily $Q$ (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | Q_medSum | m$^3$s$^{-1}$ | Median summer discharge (months May–October; data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | Q_medWin | m$^3$s$^{-1}$ | Median winter discharge (months November–April; data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | Q_Sum2Win| –    | Seasonality index of $Q$, as a ratio between median summer and median winter $Q$ (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | BFI      | –    | Base flow index calculated according to WMO (2008) with the “lfstat” package (version 0.9.4) in R (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
|          | flashi   | –    | Flashiness index of $Q$ as the ratio between the 5th percentile and the 95th percentile of the $Q$ time series (data for the period Q_StartDate–Q_EndDate) | Musolff (2020); Musolff et al. (2020) |
| Climate  | P_mm     | mm yr$^{-1}$ | Mean annual precipitation (period 1986–2015) | Cornes et al. (2018) |
Table B1. Continued.

| Category | Variable | Unit  | Description and method                                                                 | Data source          |
|----------|----------|-------|----------------------------------------------------------------------------------------|----------------------|
|          | P_SIsw   | –     | Seasonality of precipitation as the ratio between mean summer (June–August) and winter (December–February) precipitation (period 1986–2015) | Corones et al. (2018) |
|          | P_SI     | –     | Seasonality index of precipitation as the mean difference between monthly averages of daily precipitation and the annual average of daily precipitation (period 1986–2015) | Corones et al. (2018) |
|          | P_lambda | d\(^{-1}\) | Mean precipitation frequency \(\lambda\) as used by Botter et al. (2013) with rain days for precipitation above 1 mm (period 1986–2015) | Corones et al. (2018) |
|          | P_alpha  | mm \(d\)^{-1} | Mean precipitation depth as used by Botter et al. (2013) with rain days for precipitation above 1 mm (period 1986–2015) | Corones et al. (2018) |
|          | PET_mm   | mm yr\(^{-1}\) | Mean annual potential evapotranspiration (period 1986–2015) | Corones et al. (2018) |
|          | AI       | –     | Aridity index: \(AI = PET_{mm}/P_{mm}\) (period 1986–2015) | Corones et al. (2018) |
|          | T_mean   | °C    | Mean annual air temperature (period 1986–2015) | Corones et al. (2018) |

Author contributions. PE carried out the study, processed and curated the data, and created the figures and tables. PE, AM, and RK conceptualized and designed the study; AM and SA provided the initial ideas for the study and obtained funding. Several authors contributed to the data collection and processing; RK provided the gridded meteorological time series, simulated discharge data, and atmospheric deposition data; MW provided time series of N surplus data for the catchments; and OB collected the point source data for Germany. PE produced the original draft of the paper with contributions from AM and RK. All authors contributed to reviewing and editing the manuscript.

Competing interests. The contact author has declared that none of the authors has any competing interests.

Disclaimer. Publisher’s note: Copernicus Publications remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Acknowledgements. The authors gratefully thank all data collectors, processors, and providers, including the federal state environmental agencies and all contributors to this data set. We are especially grateful to Thomas Grau, Teresa Nitz, Joni Dehaspe, Stephanie Breese, and Sophie Ehrhardt for their contributions to data processing. The authors wish to thank the two anonymous reviewers for their valuable comments. Moreover, we gratefully acknowledge Martin Bach and Uwe Häußermann (Justus-Liebig-Universität Giessen) for the provision of the two data sets on the agricultural N surplus data for Germany. We acknowledge the E-OBS data set from the EU FP6 project UERRA (http://www.uerra.eu, last access: 8 August 2022) and the Copernicus Climate Change Service, and the data providers for the ECA&D project (https://www.ecad.eu, last access: 8 August 2022). The authors additionally acknowledge several organizations responsible for the data products used here, including the BfG, BGR, SGD, EEA, FAO, IIASA, ISRIC, ISSCAS, and JRC.

Financial support. This research has been supported by the Deutsche Forschungsgemeinschaft (grant no. 392886738).

Review statement. This paper was edited by David Carlson and reviewed by two anonymous referees.
