ABSTRACT

Auricular acupuncture/auriculotherapy is a treatment based on the detection and stimulation of acupuncture points on the auricle. The embryological hypothesis of ear acupuncture was launched in the 1970’s by Bourdiol of France. All organs develop from the foetus’s three germ layers, the endoderm, ectoderm, and mesoderm. The ear is one of the few anatomic structures of the human body which is developed from each of these three primary tissue types.

The internal organs except for the heart and the kidneys develop from the endoderm. The endodermal organs are represented in the concha and this part of the ear is innervated mainly by the vagus nerve. The skin, endocrine and nervous systems develop from the ectoderm. These organs are represented in the tail of the helix and the lobule. These parts of the ear are innervated mostly by a branch of cervical plexus. The locomotor and lymphatic systems develop from the mesoderm tissue. These organs are to be found represented in the antihelix, the scapha and fossa triangularis of the auricle. The trigeminal nerve innervates these areas on the auricle.

In the context of these embryological and anatomical knowledge, auricular acupuncture is described with its clinical implications.

Key words: auricular, ear, acupuncture, auriculotherapy, anatomy, embryology

INTRODUCTION

Auricular acupuncture or auriculotherapy are general terms describing all diagnostic and therapeutic approaches using points on the ear. Auricle is accepted as a microsystem in which all organs are represented on the ear. Auricular acupuncture has been practised for more than 2500 years. The oldest record is Huang Di Nei Jing (The Yellow Emperor’s Classic of Internal Medicine), written in Chinese, and the oldest Western record is a report by Hippocrates (1-4). In Europe, auricular acupuncture/auriculotherapy has been applied systematically and comprehensively since Doctor Nogier introduced the inverted foetus map in 1957 (3).

Information regarding the entire organism or body part can be retrieved from the ear. There are various explanatory models for how auricular acupuncture works. The embryological hypothesis of ear acupuncture was put forward by Bourdiol in the 1970’s. All organs and tissues develop from the foetus’s three germ layers, the endoderm, ectoderm, and mesoderm. The ear is one of the few anatomic structures of the human body which is developed from each of these three primary tissue types to be found in an embryo. Paul Nogier first discovered the somatotopic presentation of the human body on the ear and reported that each tissue type in the ear had a link to the various somatotopical reflections and to the innervation related to that part of the ear (Figure 1) (1-4).

With technological improvements, increasingly more clinical trials conducted in the field of
neuroanatomy, neurophysiology, biochemistry and radiology (fMRI) are presenting evidence regarding the detailed mechanisms of auricular acupuncture/auriculotherapy in the diagnosis and treatment of diseases.

**Embryological development of the auricle**

In 1885, His described six auricular hillocks that give shape to the human auricle: three on 1st pharyngeal arch and three on 2nd pharyngeal arch (Figure 2) (5). The auricle develops from these six auricular hillocks derived from the neural crest at the dorsal ends of the first and second pharyngeal arches, on either side of the first pharyngeal cleft (Figure 3 A, B). The hillocks of 1st pharyngeal arch contribute to the tragus and the anterior part of the helix (including the root). The hillocks of 2nd pharyngeal arch contribute to the rest of the auricle including the lobule. Hillock 1 gives rise to the tragus. Hillocks 2 and 3 form the crus of the helix and the helix proper. Hillocks 4 and 5 constitute the anti-helix, and the antitragus and lobule are developed from hillock 6 (5-11). The 1st pharyngeal cleft is between the 1st and 2nd pharyngeal arches. The 1st pharyngeal cleft develops into the external auditory meatus (Figure 4). Defects in the development of 1st pharyngeal cleft can result in preauricular cysts and/or fistulas (11, 12).
Figure 3, A and B. The hillocks are fusing to form two folds surrounding the first pharyngeal cleft, which will give rise to the external auditory meatus.

Figure 4. The adult auricle with the derivatives of the six hillocks numbered.

The external ear formed over the course of foetal development, predominantly in 5th week through 20th. Development of the external ear begins at about the fifth week of foetal growth. The auricular hillocks gain maximal prominence by the end of sixth week. In the seventh week, the hillocks undergo directional growth such that they fuse and begin to form the shape of the auricle (5-11).

Pharyngeal arches are formed by cells that are derived from ectoderm, endoderm, mesoderm, and neural crest. The structures of the external and middle ear are made up of endodermal, mesodermal, and ectodermal elements of the 1st and 2nd pharyngeal arches. The external auditory canal is the anatomical remnant of the 1st pharyngeal cleft. Inner ear structures develop from the otic placode (5-11).

A cranial nerve is assigned to each pharyngeal arch. Pharyngeal arches include an aortic arch, a specific cranial nerve and associated muscle, and a cartilage skeleton. The 1st pharyngeal arch is associated with the trigeminal nerve (CN V), and the 2nd pharyngeal arch is associated with the facial nerve (CN VII) (5-11). The auricular branch of the vagus nerve (ABVN) is the remnant of a more extensive embryonic nerve which once supplied the first pharyngeal arch (13) and is thought to be derived from nerves supplying the lateral line organs (a system of sense organs used to detect movement, vibration and pressure gradient in...
surrounding water) in aquatic vertebrates, such as fish (14).

At the beginning, the auricles are in the lower neck region, but growth of the body and ramus of the mandible posteriorly and cranially moves the auricles to the side of the head at the level of the eyes. Human ear grows 0.25 mm/year throughout the entire lifetime (15). Located on the surface of the ear, between epidermis and subcutis, there are around 10,000 sensory receptors which make it possible for the ear to be used in diagnosis and treatment. The ear also has a network of arteries, veins, and lymph vessels (16).

The density of nerve fibres in the human auricle compared to other regions of the head seems rather high (17). The great auricular nerve (cervical plexus, C2-C3) supplies the descending helix and the lobule. Organs derived from ectoderm (skin, nervous system) are to be found represented in the part of the ear innervated by cervical plexus. The skin, the brain, the spinal cord, subcortex, cortex and peripheral nerves, pineal gland, pituitary gland, kidney marrow, hair, nails, sweat glands, cornea, teeth, the mucous membrane of the nose, and the lenses of the eye develop from the ectoderm. These organs are represented in the tail of the helix and the lobule. The auricular branch of the vagus nerve supplies the concha. Internal organs derived from endoderm (internal organs, except for kidney and heart) are represented in the part of the ear innervated by the vagus nerve. The auriculotemporal nerve (trigeminal nerve) supplies the ascending helix and superior helix as far as Darwin’s tubercle, the triangular fossa, the scapha, the antitragus, and the antihelix including the antihelical wall. The skeletal muscles, smooth muscles, blood vessels, bone, cartilage, joints, connective tissue, endocrine glands, kidney cortex, heart muscle, urogenital organ, uterus, uterine tubes, testicles, blood cells and lymphatic tissue develop from the mesoderm tissue. These organs are to be found represented in the antihelix, the scapha and fossa triangularis of the auricle. The trigeminal nerve connects to the brainstem by the trigeminocervical system with pain blocking impulses for the muscles and skeleton. (Figure 5) (2, 3, 14, 17-20). Motor innervation to muscles of the external ear is supplied by branches of the facial nerve (CN VII) (3).

**Data from fMRI Studies**
Different auricular areas have distinct influence on autonomic functions. Various studies examined the effects of acupuncture stimulation at different auricular areas on autonomic responses. FMRI studies are valuable in terms of demonstrating that auricular stimulation modulates the functional
state of brain areas. Romoli et al. (2014) employed fMRI to detect the differences between two stimulated acupoints and reported that specificity of auricular acupoints can be assessed by fMRI and that brain responses for the two acupoints tested might be linked to their respective therapeutic indications (21). Alimi et al. (2002) demonstrated that the corresponding point for the hand led to selectively altered fMRI changes in the somatosensory cortex for the hand of the postcentral gyrus (22). FMRI studies of invasive (surgical) vagal nerve stimulation (iVNS) and auricular transcutaneous vagal nerve stimulation (tVNS) have reported activity within the same afferent vagal projection sites (14).

**CONCLUSION**

A growing body of literature reports that auricular acupuncture/auriculotherapy exerts therapeutic effects on several disorders and can restore the homeostatic balance in patients. In the light of this, auricles could reveal to be an affordable target for non-invasive manipulation of autonomic and central nervous system functions.

By taking all these data into consideration, future studies on auricular acupuncture will be more significant and will show stronger evidence of its effect.
