Abstract
Monosodium glutamate (MSG), a commonly used flavor enhancer, has been reported to induce hepatic and renal dysfunctions. In this study, the palliative role of protocatechuic acid (PCA) in MSG-administered rats was elucidated. Adult male rats were assigned to four groups, namely control, MSG (4 g/kg), PCA (100 mg/kg), and the last group was co-administered MSG and PCA at aforementioned doses for 7 days. Results showed that MSG augmented the hepatic and renal functions markers as well as glucose, triglycerides, total cholesterol, and low-density lipoprotein levels. Moreover, marked increases in malondialdehyde levels accompanied by declines in glutathione levels and notable decreases in the activities of superoxide dismutase, catalase, glutathione peroxidase, and glutathione reductase were observed in MSG-treated group. The MSG-mediated oxidative stress was further confirmed by downregulation of nuclear factor erythroid 2–related factor 2 (Nrf2) gene expression levels in both tissues. In addition, MSG enhanced the hepatorenal inflammation as witnessed by increased inflammatory cytokines (interleukin-1β and tumor necrosis factor-α) and elevated nuclear factor-κB (NF-κB) levels. Further, significant increases in Bcl-2-associated X protein (Bax) levels together with decreases in B-cell lymphoma 2 (Bcl-2) levels were observed in MSG administration. Histopathological screening supported the biochemical and molecular findings. In contrast, co-treatment of rats with PCA...
resulted in remarkable enhancement of the antioxidant cellular capacity, suppression of inflammatory mediators, and apoptosis. These effects are possibly endorsed for activation of Nrf-2 and suppression of NF-kB signaling pathways. Collectively, addition of PCA counteracted MSG-induced hepatorenal injuries through modulation of oxidative, inflammatory and apoptotic alterations.

**Introduction**

Many chemicals have been recently introduced in food technology such as colorants, preservatives, stabilizers, emulsifiers, sweeteners, and flavor enhancers (Acar n.d.). Monosodium glutamate (MSG), the sodium salt of glutamic acid, is one of the frequently used flavor enhancers (E621) to increase food palatability and taste (Mahieu et al. 2016). By acting on particular glutamate receptors in the taste buds, it enhances markedly the taste and palatability of food (Hassan et al. 2020). It elicits the “umami” taste experience that is recognized in high glutamate foods as meat, fish, cheese, and some vegetables (del Carmen et al. 2017). Currently, MSG can be added to soups, processed meats, dietary supplements, and canned vegetables (Celestino et al. 2021). Despite of being reported as safe for human according to the last FDA reports, using of MSG as a food additive is still disputed (Shukry et al. 2020). Former reports have revealed that the consumption of MSG was associated with human metabolic syndrome, obesity, and arterial hypertension in addition to various damages in the liver, brain, thyroid, and kidney (Mahieu et al. 2016; Seiva et al. 2012). Moreover, chronic exposure to MSG evokes marked nephrotoxicity with subsequent cellular and functional damage (Sharma et al. 2014). Glomerular hypercellularity accompanied by infiltration of inflammatory cells in the kidney cortex were observed in rats injected with MSG (Dixit et al. 2014). On long-term consumption, MSG causes alkaline urine and triggers kidney stones formation with induction of tubulo-interstitial fibrosis in rats (Nahok et al. 2019). Imbalance between excessive production of free radicals and antioxidant system in cells is a major contributor to MSG-mediated hepatorenal damage (Albrahim and Binobead 2018; Eid et al. 2019; Sharma et al. 2014). Nuclear factor erythroid 2–related factor 2 (Nrf2) is a master antioxidant regulator which induces the expression of phase II antioxidant enzymes (Yuan et al. 2020). In response to oxidative damage, Nrf2 migrates to the nucleus to trigger the synthesis of antioxidant enzymes to overwhelm excess ROS and reducing DNA damage (El-Khadragy et al. 2021; Kassab et al. 2020). Nuclear factor-κB (NF-κB) is a vital regulator for inflammatory responses that triggers the pro-inflammatory gene expression as TNF-α and other cytokines (Kaewmoool et al. 2020). Accordingly, targeting the Nrf2 and NF-κB pathways could be potent therapeutic approaches to alleviate organ damage following MSG exposure.

Protocatechuic acid (PCA), 3,4-dihydroxybenzoic acid, is a major anthocyanins metabolite that is widely detected in olives, Hibiscus sabdariffa, Salvia miltiorrhiza, white grape wine, and green tea (El-Sonbaty et al. 2019; Kaewmoool et al. 2020). Several studies have addressed the multifaceted biological effects of PCA as antioxidant, anti-inflammatory, anti-hyperglycemic, and anti-apoptotic activities (Adefegha et al. 2015; Li et al. 2021). Radhiga et al. (2016) found that PCA induced marked declines in lipid profile markers (TC, TG, free fatty acid, and phospholipids) in the plasma, liver, and kidney of D-galactosamine-administered rats. Further, PCA evoked a notable hepatorenal protective effect indicated by improvement of both organ functions and structural integrity in rats treated with cadmium and D-galactosamine (Adefegha et al. 2015; Radhiga et al. 2016). Marked anti-inflammatory and antioxidative properties were also reported in PCA co-treatment against doxorubicin (Molehin et al. 2019), cadmium (Adefegha et al. 2015), methotrexate (Owumi et al. 2019), and diabetic nephropathy (Lin et al. 2011). Modulation of Nrf2 pathway was reported in PCA-injected mice with subsequent relieve of brain edema and disrupted blood brain barrier after intracerebral hemorrhage (Xi et al. 2020). Moreover, PCA provoked anti-inflammatory and anti-apoptotic activities with decreased microglial activation in lipopolysaccharide-activated BV2 cells by inhibition of the NF-κB pathway (Kaewmoool et al. 2020).

Based on its beneficial effects, PCA co-treatment may be considered as a fascinating intervention to alleviate organ damage. However, to our knowledge, no previous report in the literature focused on the effect of PCA on hepatorenal damage accompanying MSG administration in rats. Therefore, it would be worthy to study the potential therapeutic activity and the possible underlying mechanisms of PCA on both liver and kidney dysfunctions associated with MSG.

Further, PCA evoked a notable hepatorenal protective effect indicated by improvement of both organ functions and structural integrity in rats treated with cadmium and D-galactosamine (Adefegha et al. 2015; Radhiga et al. 2016). Marked anti-inflammatory and antioxidative properties were also reported in PCA co-treatment against doxorubicin (Molehin et al. 2019), cadmium (Adefegha et al. 2015), methotrexate (Owumi et al. 2019), and diabetic nephropathy (Lin et al. 2011). Modulation of Nrf2 pathway was reported in PCA-injected mice with subsequent relieve of brain edema and disrupted blood brain barrier after intracerebral hemorrhage (Xi et al. 2020). Moreover, PCA provoked anti-inflammatory and anti-apoptotic activities with decreased microglial activation in lipopolysaccharide-activated BV2 cells by inhibition of the NF-κB pathway (Kaewmoool et al. 2020).

Based on its beneficial effects, PCA co-treatment may be considered as a fascinating intervention to alleviate organ damage. However, to our knowledge, no previous report in the literature focused on the effect of PCA on hepatorenal damage accompanying MSG administration in rats. Therefore, it would be worthy to study the potential therapeutic activity and the possible underlying mechanisms of PCA on both liver and kidney dysfunctions associated with MSG.
exposure in rats. Oxidative stress, inflammatory, and apoptotic biomarkers were assessed on the biochemical and molecular levels.

Materials and methods

Chemicals

Monosodium glutamate (MSG; purity ≥ 99%) and PCA with purity ≥ 97% were purchased from Sigma-Aldrich (St. Louis, MO, USA).

Experimental animals

Adult male Wister albino rats (150–200 g body weight; 8–10 weeks old) were obtained from VACSERA (Helwan, Cairo, Egypt) and used for this study. The housing of animals was under controlled laboratory conditions of temperature (22–24 °C), humidity (50–60%), and 12-h light/dark cycle. During the study, rats were fed on standard rodent balanced diet and freely supplied with water.

Study design and treatment protocol

Rats (N= 40) were assigned into four equal groups of ten rats each and orally treated with either MSG and/or PCA per day for seven days:

Group 1 (Control): rats orally received normal saline (0.9% NaCl).
Group 2 (PCA): rats were administered orally with 100 mg/kg of PCA via a gavage needle for 7 days according to a previous report (Li et al. 2021).
Group 3 (MSG): rats were treated with 4 g/kg of MSG for seven days according to a previous report (Abdel Baky et al. 2009; Eid et al. 2019).
Group 4 (PCA+MSG): rats were received 100 mg/kg of PCA and 4 g/kg of MSG for 7 days.

The treatment with PCA was done 120 min before the administration of MSG. After 24 h from the last treatment, animals were euthanized by intraperitoneal injection with 90–100 mg ketamine and 10 mg xylazine kg⁻¹. Blood samples were collected and allowed to coagulate for serum separation. The liver and kidney were directly dissected and divided into three parts. The first portion was utilized for preparing tissue homogenates (10% w/v) and equipped by mixing a specified weight of the tissue with ice-cold 50 mM Tris-HCl buffer (pH 7.4) followed by centrifuging at 3000 × g for 10 min at 4 °C. The resultant supernatant was stored at −20 °C for biochemical analysis. The second portion was kept at −80 °C for analysis of gene expression. The third portion was preserved in 10% of neutral-buffered formalin for histopathological examination.

Estimation of liver and kidney function markers

Serum parameters of liver functions (ALT and AST) were calorimetrically measured using standard kits (Biodiagnostic, Giza, Egypt) based on the methods described by (Reitman and Frankel 1957). Also, renal function markers (urea and creatinine) were evaluated using commercial kits (Biodiagnostic, Giza, Egypt) based on the described protocol by Fawcett and Scott (1960) and Schirmeister (1964), respectively, following the manufacturer’s information.

Assessment of glucose level and lipid profile biomarkers

Levels of total cholesterol (TC) and triglycerides (TG) were estimated using standard kits (Biodiagnostic, Giza, Egypt) according the procedures illustrated by Allain et al. (1974) and Fossati and Prencipe (1982), respectively, following the manufacturer's information. The level of serum glucose was determined according to the method described by (Trinder 1969).

Oxidative stress and antioxidant biomarkers

Levels of renal and hepatic glutathione (GSH) and the non-enzymatic antioxidant marker were determined colorimetrically utilizing Elaman’s reagent according to the method of by Ellman (1959). Lipid peroxidation was assessed in terms of malondialdehyde (MDA) according the method established by Ohkawa et al. (1979). Measurement of the activities of superoxide dismutase (SOD) was done based on the capability of SOD to inhibit the reduction of nitroblue tetrazolium dye as reported by Sun et al. (1988). In addition, catalase (CAT) activities was estimated according to the decomposition rate of H₂O₂ following the method of Aebi (1984). GSH peroxidase (GPx) and GSH reductase (GR) were assessed by determining the oxidation rate of NADPH at 340 nm and reduction rate of NADPH in the presence of glutathione according to Paglia and Valentine (1967) and Factor et al. (1998), respectively.

RNA extractions, reverse transcriptions, and qRT-PCR

Total RNA was isolated from the liver and kidney samples by TRIzol reagent (Qiagen, Germantown, MD, USA) following the manufacturer’s instructions. Then, the cDNA synthesis was conducted by a Super ScriptVILO cDNA Synthesis Kit (Life Technologies, Thermo Fisher Scientific, Waltham, MA, USA). Quantification of target mRNA levels was performed by qRT-PCR using SYBR Green MasterMix (Life
Technologies, CA, USA) with the Applied Biosystems 7500 Instrument. Primer of the Nfe2l2 gene: forward, 5′-CAGCATGACTTTGGAATTG-3′ and reverse 5′-GCAA GCGACTCATGGTCATC-3′ were prepared by Jena Bioscience GmbH (Jena, Germany). B-actin: forward, 5′-GTCCACCCCGAGTACAAC-3′ and reverse 5′-GGAT GCCTCTCTTGCTCTGG-3′ were used as the housekeeping gene. The alterations in gene expression compared to the control were assessed based on the standard 2−ΔΔCt method according to Pfaffl (2001).

Inflammatory marker determination

Pro-inflammatory markers, i.e., tumor necrosis factor-α and interleukin-1β, were assessed by ELISA kits obtained from Thermo Fisher Scientific, USA, according to the manufacturer’s instructions for TNF-α (Cat. no. BMS607-3) and IL-1β (Cat. no. BMS6002).

Apoptotic biomarkers assessment

Levels of Bax, pro-apoptotic marker, and Bcl-2, anti-apoptotic marker were estimated using commercially available ELISA kits purchased from BioVision, Inc. Manufacturers’ information for (rat Bax; Cat. No.: E4513) and Cusabio (rat Bcl-2; Cat. No.: CSB-E08854r).

Histopathological examination

Liver and kidney were fixed by immersion in neutral buffered formalin (10%), dehydrated, embedded in paraffin wax, and cut into 5-μm-thick sections. After that, liver and kidney sections were deparaffinized, stained with hematoxylin and eosin, and examined under a Nikon Eclipse E200-LED microscope (Nikon Corporation, Tokyo, Japan) for histopathological changes.

Statistical analysis

To assess the differences between groups, one-way analysis of variance (ANOVA) followed by Duncan’s multiple range test was employed. P value less than 0.05 was considered to be statistically different. Analyzed data were presented as the mean ± SD.

Results

PCA modulates MSG-induced hepatorenal dysfunction markers in rats

As shown in Table 1, marked increases (P < 0.05) were noticed in enzymatic activities of AST and ALT of as well as levels of urea and creatinine in MSG-treated rats in respect to their controls. However, rats received the treatment with PCA displayed notable declines (P < 0.05) in the aforementioned markers when compared with MSG-administered rats.

PCA counteracts MSG-induced alterations in glucose level and lipid profile in rats

In comparison with the control group, notable increases (P < 0.05) were observed in levels of glucose, TC, and TG in MSG-exposed rats. On the other hand, the administration of PCA lessened significantly (P < 0.05) the levels of the above-mentioned markers in relation with MSG-treated group as presented in Table 1.

PCA mitigates MSG-induced hepatic and renal oxidative markers in rats

Figure 1 depicts the impact of PCA administration on biomarkers of oxidative stress in the kidney and liver of MSG-treated rats. Marked elevations (P < 0.05) in lipid peroxidation products represented by MDA levels were observed in MSG-exposed rats compared to the control rats. Concomitant depletion of GSH levels (P < 0.05) was also detected in MSG-exposed rats in respect to the control. Interestingly, in comparison with the MSG-exposed rats, notable increases (P < 0.05) in GSH levels were recorded together with decreases (P < 0.05) in MDA levels in both organs in rats co-treated with PCA.

PCA boosts hepatic and renal antioxidant enzymatic activities in MSG-treated rats

MSG treatment inhibited markedly (P < 0.05) the activities of SOD, CAT, GPx, and GR in both organs compared to the control rats which reveal the diminished antioxidant power of the cells (Fig. 2). However, the co-administration of PCA at 100 mg kg−1 enhanced markedly (P < 0.05) the enzymatic levels of SOD, CAT, GR, and GPx in liver and kidney relative to the sole treatment with MSG.

To illustrate the antioxidant potency of PCA to trigger Nrf2 pathway in hepatic and renal tissues of rats exposed to MSG, the mRNA expression of Nfe2l2 was assessed in both organs of the tested groups (Fig. 3). Compared to control, MSG administration provoked significant downregulations (P < 0.05) in the mRNA expression of Nfe2l2 in the liver and kidney of treated rats. However, the co-treatment of rats with PCA-induced notable increases (P < 0.05) in Nfe2l2 expression related to the rats received only MSG.
PCA exerts anti-inflammatory effect in hepatic and renal tissues of MSG-treated rats

As displayed in Fig. 4, MSG treatment obviously prompted inflammatory reactions indicated by substantial increases \((P < 0.05)\) in levels of TNF-\(\alpha\) and IL-1\(\beta\) in hepatic and renal tissues compared to control. Notably, concomitant treatment with PCA statistically \((P < 0.05)\) relieved the levels of tested cytokines in relation with MSG-treated rats.

Due to the crucial role of NF-\(\kappa\)B signaling pathway in activation of inflammatory mediators, the effect of PCA and MSG exposure on NF-\(\kappa\)B was investigated. As illustrated in Fig 4, marked increases \((P < 0.05)\) in levels of NF-\(\kappa\)B in hepatic and renal tissues in MSG group were related to the control group. On the contrary, PCA co-treatment halted the activation of NF-\(\kappa\)B in both organs as indicated by lower NF-\(\kappa\)B levels \((P < 0.05)\) than those of MSG-treated group.

PCA lessened MSG-induced hepatic and renal apoptotic changes in rats

Rats exposed to MSG showed significant higher levels of Bax, proapoptotic marker, in hepatic and renal tissues than those in the control as shown in Fig. 5. In contrast, MSG induced significant decreases \((P < 0.05)\) in Bcl-2, anti-apoptotic marker, in the liver and kidney compared to control

Table 1  The effect of protocatechuic acid (PCA) on monosodium glutamate (MSG)-induced disturbance in the liver and kidney functions biomarkers, glucose, and lipid profile in serum samples in male rats

| Parameters          | CNT       | PCA       | MSG       | PCA+MSG   |
|---------------------|-----------|-----------|-----------|-----------|
| ALT (U/L)           | 44.89±5.71| 46.41±6.24| 84.64±7.69a| 58.96±7.45ab |
| AST (U/L)           | 65.37±9.48| 65.37±7.22| 127.74±13.90a| 75.49±12.15b |
| Urea (mg/dL)        | 30.43±7.17| 28.15±5.14| 70.37±7.21a| 43.56±7.79b |
| Creatinine (mg/dL)  | 0.52±0.11 | 0.56±0.09 | 0.63±0.08a| 0.58±0.07b |
| Glucose (mg/dL)     | 129.62±5.67| 120.33±12.32| 156.73±12.40a| 133.52±9.44b |
| Total cholesterol (mg/dL) | 34.35±6.63 | 33.05±5.21 | 58.68±11.64a| 40.11±7.62b |
| Triglyceride (mg/dL)| 107.71±15.30| 94.71±14.93| 159.52±17.02a| 121.45±16.81b |

\(a P < 0.05\) versus the control rats

\(b P < 0.05\) versus the MSG-treated rats

PCA protocatechuic acid, MSG monosodium glutamate, ALT alanine aminotransferase, AST aspartate aminotransferase

![Fig. 1](image-url)
rats. Upon pretreatment with PCA, noticeable decreases ($P < 0.05$) in Bax levels concomitant with increases ($P < 0.05$) in Bcl-2 levels were observed compared to the MSG-intoxicated rats. These findings revealed the anti-apoptotic effect of PCA in rats treated with MSG.

PCA abrogates the histopathological alterations in liver and kidney of MSG-treated rats

Histopathological screening of hepatic tissue of the control and PCA-administered rats showed typical hepatic
histoarchitecture with the central vein and well-arranged hepatocytes (Fig. 6A, B). In contrast, the liver sections of the MSG-treated rats displayed marked dilatation in the central vein and blood sinusoids in addition to disarrangement of the hepatic strands with many fat bodies. Hepatocytic vacuolation, infiltration of massive inflammatory cells, and enlarged detached Kupfer cells were also noticed. Additionally, there were abundant small fragmented pyknotic nuclei and apoptotic hepatocytes (Fig. 6C). Interestingly, the co-treatment of rats with PCA efficiently alleviated the hepatic lesions, indicate the substantial protective effect of PCA against MSG-mediated injury (Fig. 6D).

Fig. 3 The effect of protocatechuic acid (PCA) on mRNA expression of Nfe2l2 in hepatic and renal tissues in monosodium glutamate (MSG)-treated rats. PCR results are expressed as mean ± SD of triplicates that were normalized to the housekeeping Actb gene and represented as fold-change. *P < 0.05 versus the control rats, †P < 0.05 versus the MSG-treated rats.

Fig. 4 The effect of protocatechuic acid (PCA) on levels of IL-1β, TNF-α, and NF-κB in hepatic and renal tissues in monosodium glutamate (MSG)-treated rats. Each value represents mean ± SD (n=7). *P < 0.05 versus the control rats, †P < 0.05 versus the MSG-treated rats.
of the glomerulus and tubules without any damage (Fig. 7A, B). Nevertheless, kidney tissue of the MSG-treated rats exhibited marked swelling in the glomeruli, decreased Bowman’s spaces, and vacuolar degeneration in addition to infiltration of inflammatory cells in the interstitial tissue. Cellular debris were observed in the tubular lumen together with cell desquamation (Fig. 7C). Notably, co-treatment with PCA protected renal tissue as evidenced by the normal histological architecture of renal glomeruli and tubules (Fig. 7D).

Discussion

MSG is widely used globally due to its high flavor enhancing quality. However, some symptoms are known as Chinese restaurant syndrome were reported after ingestion of meals with high MSG content. These symptoms include asthma, urticaria, angio-edema, rhinitis, ventricular arrhythmia, and neuropathy (Williams and Woessner 2009). Additionally, the frequency of these symptoms was reported to increase with the ingestion
of MSG on an empty stomach (Geha et al. 2000). Furthermore, MSG induced marked alterations in total plasma protein, HDL, LDL, glucose, triglycerides, insulin, and leptin, in addition to histological changes in several organs such as the heart, brain, and ovaries (Zanfirescu et al. 2019). Much attention has paid to MSG-related neurotoxicity including behavioral alterations, such as increased aggressive behavior, lessened locomotor activity, and loss of muscle strength. MSG was reported to induce notable alterations in the histology of the hippocampus and neurons together with neuronal oxidative stress and increase of brain and serum cholinesterase levels (Onaolapo et al. 2016). After being absorbed, MSG is converted into sodium ion and L-glutamate. The glutamate receptors are abundant in central nervous system, as well as other organs such as the lungs, spleen, ovaries, liver, kidneys, and heart (Gill and Pulido 2001). When these receptors are overstimulated by glutamate or glutamate analogs, this could result in ROS production, lipid peroxidation, and triggering the caspase cascade due to Ca$$^{2+}$$ influx (Mirzakhani et al. 2020). Accordingly, these changes can lead to organ dysfunction and enzymatic disturbances.

Because of their responsibility for the detoxification of toxic compounds, marked alterations in functions and structure of the liver and kidney have been detected after MSG administration for 7 days. Additionally, after dissociation of MSG to glutamate, it produces ammonium ions by oxidative deamination. Detoxification of ammonium ion is done in the liver via the urea cycle. Therefore, excess ammonium ion followed the MSG consumption could induce liver damage (Hassan et al. 2020).

PCA is a phenolic acid with wide biological activities (Abdel-Daim et al. 2018). Topically applied PCA reduced the bacterial burden of human shoulder skin and displayed marked antimicrobial activity in young healthy volunteers (Jalali et al. 2020). PCA restored the insulin responsiveness and lessened the inflammation in visceral adipose tissue taken from obese individuals (Ormazabal et al. 2018). In addition, marked neuroprotective effects were reported for PCA in Parkinson’s disease (Zhang et al. 2010), chronic intermittent hypoxia (Yin et al. 2015), and brain edema (Xi et al. 2020).

Regarding the serum biochemical results, our study revealed significant increases in serum ALT and AST levels in MSG-treated group. These results are in agreement with former studies (Albrahim and Binobead 2018; Shukry et al. 2020). Transaminases are liver function indicators as they are released into the blood circulation in cases of hepatocellular damage (Al Aboud et al. 2021). Histopathological screening demonstrated extensive hepatic damage in MSG-treated group as the presence of dilated central vein, disarranged hepatic strands, and infiltration of inflammatory cells associated with some apoptotic hepatocytes, which is in harmony with the biochemical findings and agrees with the previous studies (Elbassuoni et al. 2018; Shukry et al. 2020). Owing to the dissociation of MSG into L-glutamate which is transformed into glutamine, the latter accumulates in hepatocytes resulting in its damage and release of ALT and AST enzymes into blood stream (Elbassuoni et al. 2018). Moreover, the ammonium ions created by MSG trigger the formation of ROS that react with polyunsaturated fatty acids in hepatic cell membrane with consequent membrane damage and release of hepatic enzymes (Shukry et al. 2020). On the other hand, PCA preserved the functional as well as the structural integrity of the hepatic cellular membrane as demonstrated by restoring serum levels of AST and ALT enzymes and the pathological alterations. These findings reveal the membrane stabilizing
activity of PCA and support former results of the hepatoprotective role of PCA (Adedegha et al. 2015; Ibitoye and Ajiboye 2020; Radhiga et al. 2016).

Linked with the aforementioned alterations, we observed higher levels of glucose, TC, and TG in MSG-exposed rats. Our findings are in harmony with previous studies (Ibegbulem et al. 2016; Seiva et al. 2012; Shukry et al. 2020). Since MSG interfere with the hepatic functional status, the hepatic metabolism of lipoproteins may be negatively affected by MSG (Ibegbulem et al. 2016). Further, MSG could activate coenzyme A reductase, the limiting factor of cholesterol synthesis, which in turn increase serum TG and TC (Shukry et al. 2020). High blood glucose level possibly attributed to encouragement of hepatic gluconeogenesis as well as low tissue insulin sensitivity (Seiva et al. 2012). On the other hand, concomitant PCA administration with MSG provoked potent hypolipidemic and hypoglycemic activities which agree with recent studies (El-Sonbaty et al. 2019; Li et al. 2020). PCA showed notable decrease in the activity of pancreatic lipase that is essential for absorption of triglycerides from the gastrointestinal tract (Li et al. 2020). Similar results were previously reported in diabetic and D-galactosamine-exposed rats (Harini and Pugalendi 2010; Radhiga et al. 2016). Also, PCA displayed marked decreases in lipid profile biomarkers associated with coronary artery disease in rats fed on high fat and fructose diet (Li et al. 2020).

To assess renal functionality in response to MSG administration, serum levels of urea and creatinine were measured in our study. Compared to the control group, significant increases were recorded in urea and creatinine in MSG-treated group, and these are in agreement with previous studies (del Carmen et al. 2017; Elbassuoni et al. 2018). Moreover, renal histopathological finding revealed swollen glomeruli, vacuolar degeneration, and desquamation. Renal damage in MSG-exposed rats may refer to the damage in convoluted tubules and Bowman’s corpuscles. In addition, MSG was reported to alter the tubular reabsorption, glomerular filtration rate, and renal blood flow (Sharma 2015). All these factors may be endorsed for the nephrotoxicity of MSG as a result of functional and cellular damage. However, administration of PCA notably lessened the serum levels of renal function markers, thus indicating the renoprotection against MSG-induced renal toxicity in rats. These results validate former studies that reported the significant renal protection of PCA against chemical-induced nephrotoxicity (Molehin et al. 2019; Owumi et al. 2019).

Supporting former studies, MSG reported to exert a prooxidant effect on the liver and kidney that is verified by the marked increase in MDA contents concomitant with notable decreases in antioxidant enzymatic activities of SOD, CAT, GR, GPx, and GSH levels in the MSG-treated group (del Carmen et al. 2017; Eid et al. 2019; Elbassuoni et al. 2018; Shukry et al. 2020). Moreover, Sharma (2015) stated that high glutamate level induces overproduction of ROS in the renal tissue through activation of α-ketoglutarate dehydrogenase which is a potential inducer for ROS generation. The kidney tissue is vulnerable to lipid peroxidation by ROS due to its richness by long-chain polyunsaturated fatty acids (Elbassuoni et al. 2018). Therefore, oxidative damage is involved in tissue damage and this is confirmed by hepatic and renal damage on histopathological examination.

Nrf2/antioxidant response element (ARE) signaling pathway is one of the crucial cellular defense strategies to combat oxidative stress condition (Albarakati et al. 2020; Kassab et al. 2020). Normally, Nrf2 is inactive and combined with Kelch-like ECH-associated protein-1 (KEAP-1) in the cytoplasm but, in cases of oxidative stress status, Nrf2 translocate to the nucleus to bind ARE. Such binding elicits the downstream activation of antioxidant and detoxification enzymes to restore cell homeostasis status (Gao et al. 2018). In our study, marked upregulation in the expression of hepatic and renal Nrf2 in MSG-exposed group was recorded as compared with the control. These results are in agreement with Gao et al. (2018) who reported marked decreases in both mRNA and protein expressions of Nrf2 in response to MSG exposure in mice. In all, our data showed that MSG induced oxidative damage via down-regulation of Nrf2 expression level associated with attenuated antioxidant defense and elevated lipid peroxidation level in hepatic and renal tissues.

Administration of PCA alleviated MSG-induced oxidative stress that was indicated by marked rises in the antioxidant enzymes activities and the level of GSH in both organs in addition to significant decreases in MDA levels. Studies have shown that the antioxidant potential of PCA is ten times than that of α-tocopherol (Song et al. 2020). The existence of hydroxyl groups in the chemical structure of PCA renders it as a hydrogen atom donor for reduction of peroxyl radicals and halt their injurious action on the cellular membrane and cellular components (Owumi et al. 2019). These results are consistent with previous investigations that stated the protective effects of PCA against oxidative damage in the liver and kidney in rat models (El-Sonbaty et al. 2019; Ibitoye and Ajiboye 2020; Molehin et al. 2019). PCA stimulates the activities of endogenous antioxidant enzymes such as CAT, SOD, GST, GR, and GPx as well as decreasing levels of ROS and MDA (Li et al. 2021; Song et al. 2020). Additionally, PCA-mediated hepatorenal protection may be endorsed for marked elevation in GSH level that increase the cellular GSH bioavailability to scavenge free radicals generated by MSG as reported by former authors (Farombi et al. 2016; Owumi et al. 2019).

To further illustrate the antioxidant potential of PCA on the liver and kidney of MSG-treated rats, the gene expression of Nfr2 was investigated. PCA induced marked upregulation in Nfr2 pathway that is responsible for the increased enzymatic activities of SOD and CAT, and this is consistent with previous studies (Ibitoye and Ajiboye 2020; Vari et al. 2011). The upregulation of
Nrf-2 expression by PCA results in a massive translocation to the nucleus, where it can bind to the ARE sequences, inducing the gene expression encoding for the majority of phase 2 detoxifying and antioxidant enzymes (Varì et al. 2011).

Furthermore, MSG has been shown to trigger inflammatory responses evidenced by elevated IL-1β and TNF-α levels and histopathological findings in the liver and kidney of exposed rats that is similar to what has been reported previously (Banerjee et al. 2020; Mirzakhani et al. 2020). Oxidative stress has been shown to enhance pro-inflammatory gene expression which is associated with elevated inflammatory cytokines (TNF-α and IL-1β) (Al-Megrin et al. 2020). Also, it was reported that excess exposure to exogenous glutamate enhanced the transcriptional levels of pro-inflammatory cytokines in the brain and intestine (Xu et al. 2005). Roman-Ramos et al. (2011) found that MSG exposure stimulates the activation of peroxisome proliferator-activated receptors which control the pro-inflammatory cytokine signaling pathways in hepatic and fatty tissues. TNF-α triggers the transcription factor NF-κB, critical regulator for inflammation, which is translocated to the nucleus with consequent activation of target inflammatory genes. In our study, marked increases in levels of hepatic and renal NF-κB were observed in MSG-treated group. Banerjee et al. (2020) reported an increase in NF-κB (p65) immune reaction in hepatic and cardiac tissues of MSG-fed rats.

On the contrary, PCA administration decreased the levels of IL-1β, TNF-alpha, and NF-κB in the liver and kidney of rat treated with MSG. Similar findings were reported in rats injected with methotrexate and co-treated with PCA (Owumi et al. 2019). PCA elicited significant anti-inflammatory activities in various animal models such as paw edema, cotton pellet granuloma, and Freund’s adjuvant arthritis (Lende et al. 2011). Further, marked downregulation in inducible nitric oxide synthetase and cyclooxygenase-2 expressions was noticed in the kidney of doxorubicin-injected rats (Molehin et al. 2019). PCA employs its anti-inflammatory effect via decreasing of the production of inflammatory mediators via modulating their gene and protein expressions involving NF-κB, MAPKs, and STAT3 signaling pathways (Kaewmool et al. 2020). This indicates that PCA restrained MSG-induced inflammatory responses in the liver and kidney via reducing NF-κB translocation to the nucleus with consequent suppression of target genes encoding the pro-inflammatory cytokines.

Our study also focused on the protective properties of PCA against MSG-induced cell death and apoptosis. Apoptosis contributes to maintain the cell death and division balance. The oxidative stress played a fundamental role to start the apoptosis (Li et al. 2021). Kidneys and livers of MSG-treated rats showed elevated Bax levels and declined Bcl-2 levels that revealed marked induction of apoptosis and agrees with former authors (Banerjee et al. 2020; Elbassuoni et al. 2018; Hassan et al. 2020; Shukry et al. 2020). Excess glutamate encouraged the influx of Ca²⁺ which disrupts the internal mitochondrial membrane potential, with result to disturbed mitochondrial permeability to apoptotic markers (Shukry et al. 2020). On the contrary, PCA co-treatment elicited a significant anti-apoptotic effect demonstrated by decreasing the level of Bax and increasing the level of Bcl-2 in the liver and kidney of MSG-received rats. Bcl-2 is a negative regulator of cellular death that protects cells against apoptotic damage, while Bax is a positive regulator of cellular death that promotes or accelerates cell death. Moreover, upregulated Bcl-2 hinder the mitochondrial release of cytochrome-c to the cytosol, thus suppressing the caspase cascade and apoptosis (Liu et al. 2008). Bcl-2 also has been shown to reduce apoptosis by regulating ion transport and averting the collapse of mitochondrial membrane potential mediated by chemical agents (Guan et al. 2006). Marked decreases were noticed in caspase-3 activities in the liver and kidney of MTX-treated rats following PCA that signify its antagonistic effect against apoptotic cell death (Owumi et al. 2019). In vitro study revealed that PCA notably inhibited H₂O₂-induced platelet apoptosis by modulating caspase-9 and caspase-3, Bax, Bcl-xL, and cytochrome-c with involvement of PI3K/Akt/GSK3β signaling pathway (Ya et al. 2021). Anti-apoptotic activity of PCA was reported previously against various chemicals and toxic compounds (Al Olayan et al. 2020; Guan et al. 2006; Li et al. 2021; Liu et al. 2008).

Conclusion
In summary, this study emphasizes that administration of MSG above the reported safe limit produced liver and kidney disorders that is mediated by oxidative damage, inflammation, and apoptotic changes. On the other side, PCA restored markedly the MSG-induced injuries by boosting the endogenous antioxidant enzymes and GSH level together with inhibition of lipid peroxidation. In addition, PCA lessened tissue inflammation, apoptosis, and hyperlipidemia. Hepatoprotective and renoprotective effects of PCA may be endorsed for activation of Nrf2 antioxidant pathway and suppression of NF-kB signaling pathway. Therefore, foods with over MSG concentration can be fortified with addition of PCA to overwhelm its undesirable systemic effects.
