**Abstract**

The four-spined pygmy devil (*Arulenus validispinus* Stål, 1877) is an endemic species to the Philippines. It was described more than 140 years ago from a single female specimen. Since its description, only a single new record was known, reported by Skejo from the Lanao region in 2017 and based on a specimen from eBay. Here, we record the species from the Bukidnon Mountains. We present measurements of a male and a female we collected, with the description of the species morphology and habitat. This species differs from its congeneric Mia’s pygmy devil (*A. miae* Skejo & Caballero, 2016) by the sharp dorsal and lateral spines.

**Introduction**

The Philippines is biogeographically one of the most diverse countries due to its high number of islands (Mittermeier et al. 1998). Mindanao, a major island of the Philippines, is located on the southern part of the archipelago. Recently, discoveries of a new species and records of pygmy grasshoppers were made in Mindanao (Skejo and Caballero 2016, Tan et al. 2019, Mohagan et al. 2020). The Bukidnon is located in the central part of Mindanao and contains one of the most extensive mountain massifs of the island—the Mt. Pantaron Range—which is a major part of the central cordillera (Gronemeyer et al. 2014). The mountain region has a high biodiversity value (Coritico et al. 2018). A faunistic inventory was recently conducted in the area, during which an interesting species of pygmy grasshopper was collected, *Arulenus validispinus*, which had not been recorded for more than a century.

The four-spined pygmy devil (*A. validispinus* Stål, 1877) is an obscure species that was, until today, known only from the holotype female collected by Semper in the Philippines without specified locality (Stål 1877, Skejo and Caballero 2016, Skejo 2017) and a female specimen on eBay from the Lanao region of the island of Mindanao. The other species of the genus, Mia’s pygmy devil (*A. miae* Skejo & Caballero, 2016), inhabits the area west of *A. validispinus‘* distribution (Skejo 2017).

Our study presents, for the first time, measurements and habitat of a male *A. validispinus*.
the anterior margin to the caudal apex of the pronotum), pronotum lobe width (PW) (between the lateral lobes), pronotum height (PH) (lateral view from the bottom of the pronotum to the tip of the highest spine), fore femur length (FFL) (in lateral view, its greatest length from the tip of the dorso–basal lobe to the tip of the knee), fore femur width (FFW) (in lateral view, its greatest width), mid femur length (MFL) (in lateral view, its greatest length from the tip of the dorso–basal lobe to the tip of the knee), mid femur width (MFW) (in lateral view, its greatest width), hind femur length (HFL) (in lateral view, its greatest length from the tip of the dorso–basal lobe to the tip of the knee), hind femur width (HFW) (in lateral view, its greatest width), vertex width (VW) (between the supraocular lobules in dorsal views or between the eyes in frontal view), compound eye width (CEW) (dorsal or frontal view), and antennal length (AL) (from scapus to the tip of the last segment). The specimens collected and examined in this study were deposited in Central Mindanao University, University Museum, Zoological Section, Tettigidae collection. All measurements are shown in millimeters.

**Diagnosis of the genus.**—We collected two specimens, a male and a female, from Bukidnon. Our specimens are very similar to Stål's type specimen, which is from an unknown locality, as well as to the specimens reported by Skejo (2017) in his diploma thesis, which came from Lanao, 105.41 km from Bukidnon. The specimens of four-spined pygmy devils are dark in coloration, and as in *A. miae*, have reddish markings. Dorsum of pronotum bears four long spines: a pair between the shoulders on the bulky elevation of the discus and a pair in the metazona. Our specimens have slightly larger spines and longer ventrolateral projections (Fig. 2) than the holotype (see holotype of *A. validispinus* in Orthoptera Species File, Cigiano et al. 2020). The holotype has a third pair of wart-like spines located at the anterior apex that are not observed in our specimens.

**Comparison with congeners.**—The genus *Arulenus* is endemic to the Philippines with only two known species, *A. miae* and *A. validispinus*. *A. validispinus* is similar to *A. miae* Skejo & Caballero, 2016, and can be distinguished by the set of the following characters: (i) prozona of pronotum granulated, very wrinkly (slightly granulate, more or less smooth in *A. miae*), (ii) metazona of pronotum from 2.8/10 to 4.5/10 of pronotum length, bearing the first pair of spines higher than the second (more than 2×), from 5.1/10 to 6.5/10 of the length bearing the second pair of spines high, hind femora more robust (length/maximal width ratio 2.4 in male and 2.5 in female), and with dorsal margin undulate and tuberculate, and (iii) notable spiky ventrolateral projections of the lateral lobes (paranota).

**Material examined.**—PHILIPPINES • (2/2) 1♂ 1♀. Bukidnon, Cabanglasan, Barangay Mandahican, Sitio Miaray, Mt Pantaron, 8°27′73.0″N, 125°36′54.6″E, 1,004 masl, 03–14 Feb. 2020, AM-011, A.B. Mohagan, R.R. Patano Jr., M.S. Acola, D.O. Amper, F.P. Coritico, and V.B. Amoroso, Central Mindanao University, University Museum, Zoological Section.

**Type locality.**—The Philippines, no specified locality of the holotype label. Type series: a single female holotype, labeled Ins. Philipp., originates from Semper’s collection and is deposited in the entomological collections of the Naturhistoriska Riksmuseet in Stockholm, Sweden.

**Distribution.**—Inhabiting tropical mountainous rainforests on Mindanao (the Philippines) at 800–1,100 m above sea level: known from Lanao and Bukidnon Region (present study).

**Measurements.**—Male (N=1). BL 11.1; PL 10.4; PW 6.2; PH 5.0; FFL 4.0; FFW 0.8; MFL 4.5; MFW 0.6; HFL 6.1; HFW 2.5; VW 1.2; CEW 1.0; AL 7.2.

Female (N=1). BL 12.0; PL 10.8; PW (between the tips of the spines) 6.5; PH 5.2; FFL 4.15; FFW 0.14; MFL 4.6; MFW 0.65; HFL 6.52; HFW 2.65; VW 1.24; CEW 1.1; AL 7.6.

**Habitat and ecology.**—The species is found on tree bark in the montane forest (Fig. 3), similar to the habitat of *A. miae* and *Spartolus pugi-natus Stål, 1877* (Mohagan et al. 2020). The associated vegetation consists of the following species of trees: *Shorea spp.*, *Lithocarpus spp.*, *Ficus spp.*, *Pinanga spp.*, and ferns: *Sphaerocoptis elemertii*, *S. poly poda*, *Al sophila fuliginosa*, *Taenitis blechnoides*, *Schizaea dichotoma* and *Selaginella spp.* Besides the Lanao region (Skejo 2017), here we report the species from the Bukidnon region, more specifically Mt. Pantaron, Sitio Miaray, Barangay Mandahican, Cabanglasan. These records finally confirm that *A. validispinus* inhabits Mindanao island in the Philippines—an answer to a 140-year old question of this species’ distribution.
Fig. 2. Habitus of the four-spined pygmy devil, *Arulenus validispinus* Stål, 1877, a male from Bukidnon (Mt. Pantaron) in A. dorsal and B. lateral view.

Fig. 3. Habitat of the four-spined pygmy devil, *Arulenus validispinus* Stål, 1877, in A. lower and B. upper lowland dipterocarp rainforest of Mt. Pantaron (about 1,004 masl).
