Abstract: In the paper, we consider a stochastic gradient descent algorithm in combination with
a dropout method. We used the theory of intuitionistic fuzzy sets for the assessment of the
equivalence of the respective assessment units. We also consider a degree of uncertainty when
the information is not enough.
Keywords: Neural networks, Dropout algorithm, Generalized net, Stochastic gradient descent
algorithm, Intuitionistic fuzzy sets.
2010 Mathematics Subject Classification: 68Q85, 03E72.

1 Introduction

Stochastic gradient descent is a very popular and common algorithm used in various machine
learning algorithms, the most important being the basis of Neural Networks (NN). Gradient
descent is a method of finding a local extremum (minimum or maximum) of a function by moving
along the gradient. Dropout \cite{[25]} works by switching off neurons in a network during training to
force the remaining neurons to take on the load of the missing neurons. This is typically done
randomly with a certain percentage of neurons per layer being switched off. To find the average weight of each neuron, we use $avg_k$ and $avg_k$ is the average weight input of a neuron on the $k$-th layer and $W_{jk}^{(i)}$ is the matrix of the weight for the current iteration $i$ before beginning the training and $n$ is the number of neurons in the $k$-th layer.

$$avg_k = \frac{1}{n} \sum_{j=1}^{n} (|W_{jk}^{(i)}|)$$

In the present work, we use the apparatus of intuitionistic fuzzy sets, defined by Atanassov [1, 2] in 1983 as an extension of the theory of fuzzy sets created by L. Zadeh [28].

Let $E$ be a fixed set. The set $A^*$ is called intuitionistic fuzzy set if there is:

$$A = \{ \langle x, \mu_A(x), \nu_A(x) \rangle | x \in E \},$$

where functions $\mu_A : E \rightarrow [0; 1]$ and $\nu_A : E \rightarrow [0; 1]$, set respectively the degree of membership and non-membership of the elements $x \in E$ to the set $A$, which is a subset of $E$ and for each $x \in E$:

$$0 \leq \mu_A(x) + \nu_A(x) \leq 1.$$

The function $\pi_A$ that sets the degree of uncertainty of the membership of the elements $x \in E$ to the set $A$ is determined by the formula:

$$\pi_A(x) = 1 - \mu_A(x) + \nu_A(x)$$

In the case of a fuzzy set $\pi_A(x) = 0$, for each $x \in E$.

The comparison between the elements of any two Intuitionistic fuzzy sets, say $A$ and $B$, involves a double comparison between the degree of membership and non-membership of the respective elements to the two networks.

In intuitionistic fuzzy logic (IFL) [4, 6], the degree of membership and non-membership can be noted as:

$$\mu_A(x) = \frac{m}{u}, \quad \nu_A(x) = \frac{n}{u},$$

where $m$ is the lower boundary of the “narrow” range; $u$ – the upper boundary of the “broad” range; $n$ – the upper boundary of the “narrow” range.

### 1.1 Generalized nets

Generalized nets (GNs) [3, 5, 7] are defined in a way that is principally different from the ways of defining the other types of Petri nets. During the time GN have become a tool for modelling parallel operating systems. Models for neural networks [8, 9] and data mining methods [11–14] have been developed.

The first basic difference between GNs and ordinary Petri nets is the “place – transition” relation. Here the transitions are objects of a more complex nature. A transition may contain $m$ input places and $n$ output places where $m, n \geq 1$.

Formally, every transition is described by a seven-tuple (Fig. 1):

$$Z = \langle L', L'', t_1, t_2, r, M, \square \rangle,$$
where:
(a) $L'$ and $L''$ are finite, non-empty sets of places (the transition's input and output places, respectively). For the transition in Fig. 1 these are

$$L' = \{ l'_1, l'_2, \ldots, l'_m \}, \quad L'' = \{ l''_1, l''_2, \ldots, l''_n \};$$

(b) $t_1$ is the current time-moment of the transition’s firing;
(c) $t_2$ is the current value of the duration of its active state;
(d) $r$ is the condition of the transition to determine which tokens will pass (or transfer) from the inputs to the outputs of the transition; it has the form of an Index Matrix:

$$r = \begin{bmatrix}
  l'_1 & l''_1 \\
  l'_2 & l''_1 \\
  \vdots & \vdots \\
  l'_m & l''_1 \\
\end{bmatrix}, 

r_{i,j} \text{ is the predicate that corresponds to the } i\text{-th input and } j\text{-th output place. When its truth value is "true", a token from the } i\text{-th input place transfers to the } j\text{-th output place; otherwise, this is not possible;}

(e) $M$ is an IM of capacities of transition’s arcs:

$$M = \begin{bmatrix}
  l'_1 & l'_j & \ldots & l''_1 \\
  \vdots & \vdots & \ddots & \vdots \\
  l'_1 & l'_j & \ldots & l''_n \\
\end{bmatrix}, 

m_{i,j} \geq 0 \text{ – natural number}; 

(f) \square \text{ is an object of a form similar to a Boolean expression. It may contain as variables the symbols that serve as labels for a transition’s input places, and } \square \text{ is an expression built up from variables and the Boolean connectives } \land \text{ and } \lor \text{ and the semantics of which is defined as follows:}
∧ (l₁, l₁₂, ..., lₙₐ) – every place (l₁, l₁₂, ..., lₙₐ) must contain at least one token,
∨ (l₁, l₁₂, ..., lₙₐ) – there must be at least one token in all places (l₁, l₁₂, ..., lₙₐ),
where \( \{ l₁, l₁₂, ..., lₙₐ \} \subset L' \). When the value of a type (calculated as a Boolean expression) is “true”, the transition can become active, otherwise it cannot.

2 Generalized net model

![Generalized net model](image)

Figure 2. A Generalized net model of the Stochastic Gradient Descent and Dropout Algorithm with intuitionistic fuzzy evaluations

The following tokens stay in the generalized net.

- In place \( S_G \) – one \( \alpha_G \) token with characteristic “Random number generator” for generalizing weight coefficients.
- In each place \( S_F \) one \( \alpha \) token, \( 1 \leq i \leq k \), with the characteristic “Transfer of a function from the \( i \)-th layer to the neural network”.
- In place \( S_T \) – one \( \alpha \) token with characteristic “Learning objective for neural network output”.
- In place \( S_EZ \) – one \( \alpha_{ez} \) token with characteristic “Pre-fixed error in neural network training”.

The generalized net includes the following set of seven transitions:

\[ A = \{ Z₁, Z₂, Z₃, Z₄, Z₅, Z₆, Z₇ \}, \]

where the following events take place:

- \( Z₁ \) – generalizing random vector for values of the weight matrix \( W \);
- \( Z₂ \) – calculating the \( \text{avg}_K \).
• $Z_3$ – calculating the gradient;
• $Z_4$ – calculating the outputs $a_k = F_k(n_k)$ from the $k$-th layer;
• $Z_5$ – determining the difference between the received value ($S_O$) and the fixed learning target and the least-square error between them;
• $Z_6$ – determining whether the artificial neural network (ANN) has been learnt or not;
• $Z_7$ – calculating the new weight coefficients.

Each of the seven transitions is described below in detail.

Transition $Z_1$ has the following form:

$$Z_1 = \langle \{S_{EN}, S_G\}, \{S_W, S_G\}, R_1, \vee(S_{EN}, S_G) \rangle,$$

where:

$$R_1 = \begin{bmatrix} S_W & S_G \\ S_{EN} & false & true \\ S_G & W_{G,W} & true \end{bmatrix},$$

and $W_{G,W} =$ “Random vector is generated”.

At place $S_W$ the token obtains the characteristic “weight coefficient $W$”.

Transition $Z_2$ has the following form:

$$Z_2 = \langle \{S_W, S_{NW}, S_{DW}\}, \{S_D, S_{FZ}, S_{DW}\}, R_2, \vee(\wedge(S_W, S_{NW}), S_{DW}) \rangle,$$

where:

$$R_2 = \begin{bmatrix} S_D & S_{FZ} & S_{DW} \\ S_W & false & false & true \\ S_{NW} & false & false & true \\ S_{DW} & W_{DW,D} & W_{DW,FZ} & true \end{bmatrix},$$

and

- $W_{DW,D} =$ “the calculated averages values for $W$ are retained to obtain the outputs from the layers”,
- $W_{DW,FZ} =$ “the calculated averages values for $W$ receive an intuitionistic fuzzy estimate and are preserved”.

At place $S_D$ the token obtains the characteristic “average value”.

Transition $Z_3$ has the following form:

$$Z_3 = \langle \{S_D, S_{AW}\}, \{S_A, S_{AW}\}, R_2, \vee(\wedge(S_D), S_{AW}) \rangle,$$

where:

$$R_3 = \begin{bmatrix} S_A & S_{AW} \\ S_D & false & true \\ S_{AW} & W_{AW,A} & true \end{bmatrix},$$

and $W_{AW,A} =$ “the calculated averages for $W$ are retained to obtain the outputs from the layers”.

84
At place $S_A$ the token obtains the characteristic “Output of the NN with input $DN$ and weight coefficient $W$”.

Transition $Z_4$ has the following form:

$$Z_4 = \langle \{S_A, S_F, S_{OW}\}, \{S_O, S_{OW}\}, R_4, \lor(\land(S_A, S_F), S_{OW})\rangle,$$

where:

$$R_4 = \begin{array}{c|cc}
S_O & S_{OW} \\
\hline
S_A & \text{false} & \text{true} \\
S_F & \text{false} & \text{true} \\
S_{OW} & W_{OW,\lor} & \text{true}
\end{array},$$

and $W_{OW,\lor} = “The neural layer’s output is calculated”$.

At place $S_O$ the token obtains the characteristic “Output of the NN with input $AN$, weight coefficient $W$ and transfer functions $F$”.

Transition $Z_5$ has the following form:

$$Z_5 = \langle \{S_O, S_T\}, \{S_E\}, R_5, \land(S_O, S_T)\rangle,$$

where:

$$R_5 = \begin{array}{c|c}
S_E & S_O \\
\hline
\text{true} & S_T \text{ true}
\end{array}.$$

At place $S_E$ the token obtains the characteristic “The value of the least square error in the network’s learning”.

Transition $Z_6$ has the following form:

$$Z_6 = \langle \{S_E, S_{EZ}, S_{AL}\}, \{S_{NL}, S_L, S_{AL}\}, R_6, \land(S_E, S_{EZ}, S_{AL})\rangle,$$

where:

$$R_6 = \begin{array}{c|ccc}
S_{NL} & S_L & S_{AL} \\
\hline
S_E & \text{false} & \text{false} & \text{true} \\
S_{EZ} & \text{false} & \text{false} & \text{true} \\
S_{AL} & W_{AL,\lor} & W_{AL,L} & \text{true}
\end{array},$$

and

- $W_{AL,\lor} = “The NN is not learnt enough”$,
- $W_{AL,L} = “The NN is learnt”$.

At place $S_{NL}$ the token obtains the characteristic: “The value of the received error for recalculating the weight coefficients”.

Transition $Z_7$ has the following form:

$$Z_7 = \langle \{S_{NL}, S_{ANW}\}, \{S_{NW}, S_{ANW}\}, R_7, \land(S_{NL}, S_{ANW})\rangle,$$

where:
Initially, we calculate the average value for the layer,

\[ S_{\text{avg}} = \frac{1}{pn} \sum_{i=1}^{i=p} \sum_{j=1}^{j=k} W_{ij}. \]

We obtain \( S_{\text{avg neg}} \), in case when \( S_{\text{avg}} > W_{ij} \), we obtain the degree of membership having the following form:

\[ \mu_{\text{layer}} = \frac{S_{\text{avg neg}}}{n}. \]

We obtain \( S_{\text{avg pos}} \), in case when \( S_{\text{avg}} < W_{ij} \), we obtain the degree of non-membership having the following form:

\[ \nu_{\text{layer}} = \frac{S_{\text{avg pos}}}{n}. \]

We obtain \( S_{\text{avg equal}} \), in case when \( S_{\text{avg}} = W_{ij} \), we obtain the uncertainty:

\[ \pi_{\text{layer}} = \frac{S_{\text{avg equal}}}{n}. \]

The following new values can be obtained:

\[ V_{\text{strong opt}} = (\mu_{A1}(x) + \mu_{A2}(x) + \mu_{A3}(x) + \ldots + \mu_n(x)) - \mu_{A1}(x)\mu_{A2}(x) - \mu_{A1}(x)\mu_{A3}(x) - \mu_{A2}(x)\mu_{A3}(x) - \ldots - \mu_{A_{n-1}}(x)\mu_{An}(x) + \ldots + \mu_{A1}(x)\mu_{A2}(x)\mu_{A3}(x)\ldots\mu_n(x), v_{A1}(x)v_{A2}(x)v_{A3}(x)\ldots v_n(x)) \]

\[ V_{\text{opt}} = (\min(\mu_{A1}(x)\mu_{A2}(x)\mu_{A3}(x)\ldots\mu_n(x)), \min(v_{A1}(x)v_{A2}(x)v_{A3}(x)\ldots v_n(x))) \]

\[ V_{\text{avg}} = (\mu_{A1}(x) + \mu_{A2}(x) + \mu_{A3}(x) + \ldots + \mu_n(x)) / n, (v_{A1}(x) + v_{A2}(x) + v_{A3}(x) + \ldots + v_n(x)) / n \]

\[ V_{\text{pes}} = (\min(\mu_{A1}(x)\mu_{A2}(x)\mu_{A3}(x)\ldots\mu_n(x)), \max(v_{A1}(x)v_{A2}(x)v_{A3}(x)\ldots v_n(x))) \]

\[ V_{\text{strong pes}} = (\mu_{A1}(x)\mu_{A2}(x)\mu_{A3}(x)\ldots\mu_n(x), v_{A1}(x) + v_{A2}(x) + v_{A3}(x) + \ldots + v_n(x) - v_{A1}(x)v_{A2}(x) - v_{A1}(x)v_{A3}(x) - v_{A2}(x)v_{A3}(x) - \ldots - v_{A_{n-1}}(x)v_{An}(x) + \ldots + v_{A1}(x)v_{A2}(x)v_{A3}(x)\ldots v_n(x)). \]
3 Conclusions

A new generalized net model, simulation of the neural network learning process combining the Dropout Method and Stochastic Gradient Descent are considered. The model makes it possible to consider the different stages in the training of the neural network. An estimation with intuitionistic fuzzy sets is used. The intuitionistic fuzzy evaluations reflect the results of the system. A degree of uncertainty is also considered in case of insufficient information. A generalized net model is used to describe the whole process.
