Abstract— In this paper, a novel method for lumen boundary identification is proposed using Neutrosophic c-means. This method clusters pixels of the intravascular optical coherence tomography image into several clusters using indeterminacy and Neutrosophic theory, which aims to detect the boundaries. Intravascular optical coherence tomography images are cross-sectional and high-resolution images which are taken from the coronary arterial wall. Coronary Artery Disease cause a lot of death each year. The first step for diagnosing this kind of diseases is to detect lumen boundary. Employing this approach, we obtained 0.972, 0.019, 0.076 mm², 0.32 mm, and 0.985 as mean value for Jaccard measure (JACC), the percentage of area difference (PAD), average distance (AD), Hausdorff distance (HD), and dice index (DI), respectively. Based on our results, this method enjoys high accuracy performance.

Keywords—: Neutrosophic c-means; boundary detection; Intravascular optical coherence tomography; data clustering; coronary Artery disease;

I. INTRODUCTION

Atherosclerotic cardiovascular disease (CVD) [1], otherwise known as Coronary artery disease [2], is a long-term illness which improves in one’s life and usually reaches to a progressed level by demonstrating its’ signs [1]. This illness is mainly caused by the integration of atherosclerotic plaques on the coronary artery wall, and as a result of which the lumen area decreases [2]. One evaluation proposed that 80% of all CVD death happens in developing countries [1]. intravascular optical coherence tomography (IVOCT), which is one of the most precise imaging technologies can afford cross-sectional images and micrometer-scale [3]. IVOCT can capture the most casual layers of the arterial wall in addition to the stent struts, and the vascular tissue surrounding them, and lumen region [4].

Nowadays, the majority of studies based on IVOCT images are fulfilled manually. On the other hand, considering large datasets is only possible by employing automatic methods [5]. Automatic Lumen boundary detection methods are divided into three categories, including region-based methods, edge-based methods, and learning based method [6, 7]. Region-based methods including statistical [8] and graph-cut methods [9], edge-based methods such as active contour [4], and learning-based methods including neural networks [10], deep learning [7, 11] and clustering [12, 13].

Data clustering is a significant method in pattern recognition, machine intelligence, and computer science [14]. Data clustering aims to identify identical data such as a set of patterns, points, or objects in a group. Cluster analysis runs without using category labels which define objects by prior identifiers, i.e., class labels [15]. According to most of the literature, the clustering algorithms can be divided into hard and fuzzy clustering methods [16, 17]. Some clustering methods include FCM method and Neutrosophic c-means (NCM) method and so forth [16, 18]. And we propose a new clustering method in IVOCT images.

In this paper, an automatic method is proposed for IVOCT images analysis. Employing the image clustering method based on NCM [16], the automatic detection algorithm is used for vessel lumen border identification. The main purpose of this work is to detect boundary as well as outlier points in IVOCT images. To do so, indeterminacy in Neutrosophic (NS) domain which is followed by introducing this set for NCM clustering cost function in IVOCT images is proposed. Using the indeterminacy of data is very useful for boundary detection. However, Methods for lumen boundary detection in most of the papers do not consider indeterminacy. In this paper, we propose a method based on indeterminacy and NS theory for lumen border detection in IVOCT images. The NCM method first applies the NS objective function to the image then apply a mean filter for.
II. PRELIMINARIES

The method which proposed in this paper is based on NS and Fuzzy clustering. In this section, we are going to introduce these approaches and review them.

A. FCM

The Fuzzy C Means (FCM) is the first fuzzy method in which the regions of an image are clustered [19]. In this method, the probability that a pixel belongs to a particular cluster is computed by using the membership function [20] which is denoted in (1). This equation represents a cost function that is minimized iteratively in the optimization process to improve the accuracy.

\[ u_{ij} = \frac{1}{\sum_{t=1}^{N} \left( \frac{|X_j - v_t|}{|X_j - v_k|} \right)^{m-1}} \]  
\[ v_i = \frac{\sum_{j=1}^{N} u_{ij}^m X_j}{\sum_{j=1}^{N} u_{ij}^m} \]

Firstly, we guess the cluster center for each of the clusters. The local minimum of the cost function is found by converging the FCM for \( v_i \). At each two successive iteration steps, we can assess the differences in the membership function or the cluster center to detect the convergence [20]. As it is shown in [21], the FCM methods are highly influenced by the noise presence in the input data.

B. Neutrosophic

One of the newly brought up branches of philosophy is called Neutrosophy. This theory contemplates A in a correlation with its opposite, Anti-A, and the neutrality of it, Neut-A, which is neither A nor Anti-A [22]. NS describes a pixel \( P \) in the image as \( p(t,i,f) \) as follows: \( t \) is the true percentage, \( i \) is the indeterminacy percentage, and \( f \) is the false percentage. The image pixels are turned into the NS domain which is presented by \( T(i,j), I(i,j), F(i,j) \) where \( t \) varies in \( T \), \( i \) varies in \( I \), and \( f \) varies in \( F \). The membership values shown by \( T(i,j), I(i,j) \) and \( F(i,j) \) are as follows [18, 23]:

\[ T(i,j) = \frac{\tilde{g}(i,j) - \tilde{g}_{\text{min}}}{\tilde{g}_{\text{max}} - \tilde{g}_{\text{min}}} \]

III. METHOD

Based on the NCM method which combines the FCM approach and the NS theory, we propose the lumen border detection methodology which contains two main stages: the preprocessing stage and the employment of the Lumen detection using NCM method in the second stage (Fig.1).

A. Lumen detection using NCM method

In IVOCT image clustering we are looking for boundaries which are indeterminate parameters. The methods that have been used in previous works didn’t use indeterminacy for lumen border detection in IVOCT images. We implement a boundary detection algorithm which is able to use indeterminacy. The theory of indeterminacy figures out the factor of the noise presence which is solved in NCM by using the NS theory. In this method, at first, we apply the NS objective function to the pixels of an image and iteratively decrease the cost of the function. The three main equations, namely \( T \), \( I \) and \( F \), determine the membership degree to the determinate clusters, an ambiguity cluster, and an outlier cluster for each data point, respectively. Secondly, by using a mean filter we can smooth the results. IVOCT images include some noises such as the speckle noise. As the FCM method is highly influenced by the speckle noise, clustering the images will not be performed properly. This can be addressed through the NCM method that aims to detect boundary, employ indeterminacy and

\[ \tilde{g}(i,j) = \frac{1}{w \times w} \sum_{m=i-w/2}^{i+w/2} \sum_{n=j-w/2}^{j+w/2} g(m,n) \]

\[ I(i,j) = \frac{\delta(i,j) - \delta_{\text{min}}}{\delta_{\text{max}} - \delta_{\text{min}}} \]

\[ \delta(i,j) = \text{abs}(g(i,j) - \tilde{g}(i,j)) \]

\[ F(i,j) = 1 - T(i,j) \]

In here, \( g(i,j) \) shows the intensity value of the pixel \( P(i,j) \), the local mean value of \( g(i,j) \) is illustrated by \( \tilde{g}(i,j) \), and \( \delta(i,j) \) is the result of the absolute value of the difference between \( g(i,j) \) and \( \tilde{g}(i,j) \).
eliminate the noise which leads to an accurate and effective clustering. An objective function and membership are defined [16] to consider the indeterminacy in the clustering which leads to the definition of the following equations:

$$L(T, I, F, C) = \sum_{i=1}^{N} \sum_{j=1}^{C} (\bar{\omega}_i T_{ij})^m \|X_i - C_j\|^2$$

$$+ \sum_{i=1}^{N} (\bar{\omega}_z I_{ij})^m \|X_i - \bar{C}_{imax}\|^2 + \sum_{i=1}^{N} \delta^2(\bar{\omega}_z F_{ij})^m$$

$$\bar{C}_{imax} = \frac{C_{pi} + C_{qi}}{2}$$

$$P_j = \arg \max(T_{ij}) \quad j = 1, 2, ..., C$$

$$q_j = \arg \max(T_{ij}) \quad j \neq pi \cap j = 1, 2, ..., C$$

In equation (9), m has a constant value, and in equations (11) and (12) pi and qi are the clusters number which enjoy the biggest and the second biggest quantity of T, respectively. For each data point i, a constant value $\bar{C}_{imax}$ is calculated after the values for the pi and qi are identified [16]. In here the equations for $T_{ij}$, $I_j$, and $F_j$ are presented:

$$T_{ij} = \frac{K}{\bar{\omega}_1} (X_i - C_j)^{-\left(\frac{2}{m-1}\right)}$$

$$I_j = \frac{K}{\bar{\omega}_2} (X_i - \bar{C}_{imax})^{-\left(\frac{2}{m-1}\right)}$$

$$F_j = \frac{K}{\bar{\omega}_3} \delta^{-\left(\frac{2}{m-1}\right)}$$

$$C_j = \frac{\sum_{i=1}^{N} (\bar{\omega}_1 T_{ij})^m X_i}{\sum_{i=1}^{N} (\bar{\omega}_1 T_{ij})^m}$$

$$K = \left[ \frac{1}{\bar{\omega}_1} \sum_{j=1}^{C} (X_i - C_j)^{-\left(\frac{2}{m-1}\right)} + \right.$$  $$\left. \frac{1}{\bar{\omega}_2} (X_i - \bar{C}_{imax})^{-\left(\frac{2}{m-1}\right)} + \frac{1}{\bar{\omega}_3} (\delta)^{-\left(\frac{2}{m-1}\right)} \right]^{-1}$$

Hence, the clustering is fulfilled by using an iterative optimization method, and in each iteration, the membership $T_{ij}$, $I_j$, $F_j$ and the cluster centers $C_j$ are updated. According to the indexes of the largest and the second largest value of $T_{ij}$ at each iteration, the $\bar{C}_{imax}$ is calculated. The iteration continues until $|T_{ij}^{(k+1)} - T_{ij}^{(k)}| < \epsilon$, k shows the number of iteration steps, and $\epsilon$ is a termination criterion which is a number in the 0 to 1 interval. The following figure illustrates how our framework detects the lumen in an IVOCT image.

![Fig. 2. shows the steps of algorithm](image-url)

**B. Evaluation metrics**

To study the effect of implementing the proposed approach by using different evaluation measures, we devise an experiment in which we compare the final accuracy of our method while using the following various measures: AD, HD, JACC, PAD, and DI.

AD is defined as the average distance between automatically detected lumen and the manual lumen boundary [24].

$$AD = 1 - \frac{A_{automatic} \cap A_{manual}}{(A_{automatic} + A_{manual}) - (A_{automatic} \cap A_{manual})}$$

where $A_{automatic}$ is the boundaries which have been detected by the proposed method and $A_{manual}$ is the borders which have been defined by experts.

HD which is the maximum distance between the detected lumen and the manual lumen boundary [25].
\[ H(D_{\text{automatic}} - D_{\text{manual}}) = \max\{\max\{d(a, b)\}\} \]
\[ a \in A_{\text{automatic}}, b \in A_{\text{manual}} \]  

In equation (19), a and b are curve points of \(A_{\text{automatic}}\) and \(A_{\text{manual}}\), respectively, and d(a, b) is the Euclidean distance.

The overlapping area ratio between \(A_{\text{automatic}}\) and \(A_{\text{manual}}\) can be defined by JACC. JACC value is between 0 and 1 for the worst and the best situation, respectively [25].

\[ JACC = \frac{A_{\text{automatic}} \cap A_{\text{manual}}}{A_{\text{automatic}} \cup A_{\text{manual}}} \]  

PAD calculates the difference between \(A_{\text{automatic}}\) and \(A_{\text{manual}}\) [26]:

\[ PAD = \frac{|A_{\text{automatic}} - A_{\text{manual}}|}{A_{\text{manual}}} \]  

The similarity between the region \(A_{\text{automatic}}\) and \(A_{\text{manual}}\) is indicated by the Dice similarity index (DI). The Dice Similarity Index is as follows:

\[ DI(A, B) = \frac{2|A_{\text{automatic}} \cap A_{\text{manual}}|}{|A_{\text{automatic}}| + |A_{\text{manual}}|} \]  

Where, \(|A_{\text{automatic}}|\) and \(|A_{\text{manual}}|\) illustrate the number of pixels of the lumen area in image \(A_{\text{automatic}}\) and \(A_{\text{manual}}\). \(|A_{\text{automatic}} \cap A_{\text{manual}}|\) shows the number of pixels of the overlapping lumen area of image \(A_{\text{automatic}}\) and \(A_{\text{manual}}\). DI value is between 0 and 1 for the worst and the best situation, respectively [27].

IV. EXPERIMENTAL RESULTS

A. Dataset

The dataset includes 138 frames from a single patient. An imaging system with enabled optical coherence tomography and NIRF technologies was used to obtain imaging from a single pullback scanning, by employing a custom-made catheter. The diameter of the catheter is 0.87 mm. High-resolution cross-sectional images at an A-line rate of 120 kHz were provided by an optical coherence tomography system which its center has 1290 nm wavelength [28].

B. Figures and Tables

The NCM clustering method was applied over IVOCT images. The method labels the image pixels into multiple cluster regions. The dataset is collected for a single patient and includes a set of 138 IVOCT images. The image clustering was performed on a computer with an Intel Core i3 as CPU, 4 GB of RAM, Windows 7 64bits as the operating system and MATLAB (2018a) software. After performing the NCM method over the given dataset, the average value for DI, JACC, PAD, AD and HD evaluation measures, which are previously defined, are 0.985, 0.972, 0.019, 0.076 mm and 0.32 mm respectively. As it is depicted by the following figures, our approach achieves a higher accuracy rate than the previous works.

Fig. 3. shows the statistical indexes of evaluation metrics.

The following figure represents the final results of our method from another perspective. In this figure, the first, second and third columns sketch the original input image, the manually detected lumen and the automatic lumen detection by the NCM method respectively. As it is clearly obvious, the lumen is detected with high accuracy (the red circular shape).

Fig. 4. Three IVOCT frame (column A), along with the manually detected lumen (column B) and automatically detected lumen boundaries by NCM method (column C).
The JACC, PAD, DI, HD, and AD evaluation metrics’ mean values of proposed method are shown in table I:

| Methods                  | JACC % | HD (mm) | AD (mm²) | PAD         | DI % |
|--------------------------|--------|---------|----------|-------------|------|
| binary morphological     | 95.6   | ---     | ---      | ---         | 97.8±2.16 |
| reconstruction [29]       |        |         |          |             |      |
| Convolutional Neural     | 90.80  | ---     | ---      | ---         | 94.34 |
| Network [7]: Dataset 1   |        |         |          |             |      |
| Dataset 2                | 93.83  | ---     | ---      | ---         | 96.73 |
| Dataset 3                | 97.6±2.3 | ---   | ---      | ---         | 98.8 ± 1.2 |
| Wavelet and              | ---    | 0.084   | 0.06     | ---         | ---  |
| Mathematical Morphology  | [30]   |         |          |             |      |
| Proposed method          | 97.2±2.1 | 0.32±0.18 | 0.076±0.077 | 0.019±0.01 | 98.5±1.36 |

The evaluation measures, for the previously defined dataset, are evaluated by our Automatic lumen detection using NCM, compared with binary morphological reconstruction [29], Convolutional neural network [7], and Wavelet and mathematical morphology [30]. The final results have been shown in Table I. It is noteworthy that all the values in the table are computed by averaging the methods’ result for the whole dataset instances (138 instances for a single patient).

IVCOT papers have not used PAD metric in their evaluations yet, although this metric is essential for medical analysis. As shown in Table I, the mean value of PAD is 0.019 employing our proposed method.

DI and JACC metric achieved decent percentages, and PAD as well as AD obtained small and proper quantity. However, the guide wire effect caused high-intensity points in the lumen, resulting in inappropriate value for HD.

V. CONCLUSION

In this study, we used one of the precise clustering methods in the NS domain, whereby the boundary and noise can be identified using the NCM cost function. The purpose of this clustering was to find the lumen boundaries in the IVOCT images, which, due to the noise removal and the use of the uncertainty, have been carefully designed to detect these boundaries.

In this work, the accuracy of FCM is improved. In our future works, NCM can be combined with deep learning networks such as the convolutional neural network for image clustering. Moreover, a new method can be presented in order to define the number of clusters automatically.
