We present the recent results of top-quark physics using up to 6 fb$^{-1}$ of $p\bar{p}$ collisions analyzed by the CDF collaboration. The large number of top quark events analyzed, of the order of several thousands, allows stringent checks of the standard model predictions. Also, the top quark is widely believed to be a window to new physics. We present the latest measurements of top quark intrinsic properties as well as direct searches for new physics in the top sector.

1. Introduction

The top quark is the third generation up-type quark. It was discovered in 1995 by the CDF and DØ experiments at the Tevatron \cite{1}, in events where it is produced together with an antitop quark. It has a charge of $\frac{2}{3}e$. With a mass of $173.2 \pm 0.9 \text{ GeV}/c^2$ \cite{2}, it is the most massive elementary particle known to date. According to the standard model (SM), it has a Yukawa coupling to the Higgs boson close to unity, which hints to a possible special role in electroweak symmetry breaking. It interacts primarily by the strong interaction but also through the weak force. In 2009, the CDF and DØ experiments observed the production of a single top quark through the weak interaction \cite{3}.

Since its observation, the top quark has been extensively studied, and is currently one of the main physics programs at the Tevatron. It has a very short lifetime ($\sim 10^{-25} \text{ s}$) and hence decays before hadronizing, providing a unique opportunity to study a bare quark. Therefore, top quark physics is a window into new physics. We present the latest results from the CDF collaboration.

2. Top Quark Physics

At the Tevatron $p\bar{p}$ collider, the top quark is mainly produced in top-antitop pairs ($t\bar{t}$), through quark-antiquark (85\% contribution to $t\bar{t}$) and gluon-gluon (15\% contribution) fusion. The top quark decays through the weak force almost exclusively into a $W$ boson and a $b$ quark.

The production of top pairs is studied according to the $t\bar{t}$ decay mode: dilepton, lepton+jets and all-hadronic, depending on whether two, one, or none of the $W$ decayed leptonically. The lepton+jets is considered the golden channel because it combined a good branching fraction ($\sim 30\%$) with a good signal to background ratio. The dilepton ($ee, e\mu, \mu\mu$) channel is the cleanest but suffers from a small branching fraction ($\sim 5\%$). The all-hadronic channel has the largest branching fraction ($\sim 45\%$) but suffers from a huge level of background from QCD multijet production. An additional channel, $E_T$+jets, is used to recover events where the $e$ or $\mu$ is not identified in the detector, or when the $\tau$ decays hadronically; it also suffers from a large QCD background.

3. Top Quark Production

The SM allows predicting the $t\bar{t}$ production cross-section $\sigma(t\bar{t})$. Measurements of this cross-section test QCD calculations and allow probing new physics beyond the standard model, since new physics can enhance $t\bar{t}$ production. Next to leading order (NLO) predictions estimate the $t\bar{t}$ cross-section to be $\sigma(t\bar{t}) = 7.45^{+0.72}_{-0.63} \text{ pb}$ for a top-quark mass of $172.5 \text{ GeV}/c^2$ \cite{4}.

The most precise measurements of $\sigma(t\bar{t})$ come from the lepton+jets signature \cite{5}. This analysis uses two complementary methods: a $b$-jet tagging measurement and a topological approach based on a neural network. The combined result yields $\sigma(t\bar{t}) = 7.70 \pm 0.52 \text{ pb}$ for a top-quark mass of $172.5 \text{ GeV}/c^2$. In the dilepton channel, we measure a cross-section of $\sigma(t\bar{t}) = 7.4 \pm 1.0 \text{ pb}$ \cite{6} using 5.1 fb$^{-1}$ of data. After requiring that at least one of the jets originating from a $b$ quark by identified by the SecVtx $b$-tagging algorithm \cite{7}, we measure $\sigma(t\bar{t}) = 7.3 \pm 0.9 \text{ pb}$. In the all-hadronic channel, we measure a cross-section of $\sigma(t\bar{t}) = 7.2 \pm 1.2 \text{ pb}$ \cite{8}. Two results in the $E_T$+jets signature yield $\sigma(t\bar{t}) = 7.1 \pm 1.2 \text{ pb}$ (2/3 jets in 5.7 fb$^{-1}$) \cite{9} and $\sigma(t\bar{t}) = 8.0 \pm 1.0 \text{ pb}$ ($> 3$ jets in 2.2 fb$^{-1}$) \cite{10}. In the hadronic $\tau$+jets channel, we obtain using 2.2 fb$^{-1}$ of data $\sigma(t\bar{t}) = 8.8 \pm 4.0 \text{ pb}$ \cite{11}. Figure 14 summarizes most of the cross-section measurements at CDF.
4. Top Quark Properties

Among the properties of the top quark, its mass is the most studied. It is a fundamental parameter of the SM because it constrains the mass of the Higgs boson. Recent CDF results include a measurement in the $E_T$+jets and all hadronic final states using $5.7 \, \text{fb}^{-1}$, with a top mass respectively of $m_t = 172.3 \pm 2.6 \, \text{GeV}/c^2$ [12] and $m_t = 172.5 \pm 2.1 \, \text{GeV}/c^2$ [13]. These results, shown in figure 1, are combined with past determinations of the top mass and yield $m_t = 172.7 \pm 1.1 \, \text{GeV}/c^2$ [14], reaching a precision of $\Delta m_t/m_t = 0.63\%$ and an uncertainty on the top quark of 1.1 GeV/$c^2$. Figure 1b summarizes these results. The CDF collaboration also reported the first top mass measurement in the $\tau$+jets channel using $2.2 \, \text{fb}^{-1}$ of data, yielding $m_t = 172.7 \pm 10 \, \text{GeV}/c^2$ [11]. The mass difference between the top and antitop quark is measured to be $m_t - m_{\bar{t}} = -3.3 \pm 1.7 \, \text{GeV}/c^2$ [15], consistent with CPT symmetry.

Additional properties studied at CDF include the $W$ boson polarization of the top quark de-

cay and the forward-backward asymmetry. The $V-A$ structure of the weak interaction predicts that the $W^+$ from $t \rightarrow W^+ b$ decays are either longitudinally polarized ($\sim 70\%$) or left-handed ($\sim 30\%$), while right-handed $W$ bosons are heavily suppressed (and forbidden in the limit of a massless $b$ quark). The latest CDF measurements in the dilepton channel yield a longitudinal fraction $f_0 = 0.74^{+0.19}_{-0.18}$ and a right-handed fraction of $f_+ = -0.09 \pm 0.1$.

The forward-backward asymmetry of top pair production $A_{fb}$ is due to NLO effects and is predicted to be about 8% [16]. In the lepton+jets channel, the corrected parton level asymmetry is $16 \pm 8\%$ (48 $\pm 11\%$ for events with $m_{t \bar{t}} > 450$ GeV/$c^2$) [17], while an asymmetry of $42 \pm 16\%$ is measured in the dilepton channel [18]. The combination of these results yields $A_{fb} = 20 \pm 7\%$ [19].

5. Searches for New Physics

Several searches look for new physics in the top sector. CDF has searched for a heavy top quark $t' \rightarrow Wb$ in the lepton+jets signature [20]. Looking at $5.6$ fb$^{-1}$ of CDF data, we exclude the SM fourth generation $t'$ quark with a mass below $358$ GeV/$c^2$ at 95% confidence level. Another result searches for dark matter through the production of fourth generation quarks $t'$ decaying via $t' \rightarrow t + X$ where $X$ is dark matter [21]. Analyzing $4.8$ fb$^{-1}$ of CDF data, we exclude $m_{t'} < 360$ GeV/$c^2$ at 95% confidence level for $m_X < 100$ GeV/$c^2$. The same search is done in
the $E_T$+jets channel, thus studying events where both $W$ bosons decay hadronically [22]. To distinguish events in which the $E_T$ is due to the dark matter form those in which it is due to the mis-measurement of the jet energies, the latter uses the missing momentum flow ($P_T^E$) in the tracker as a complementary tool to the $E_T$ in the calorimeter. Looking at 5.7 fb$^{-1}$, we exclude $m_{t'} < 400$ GeV/c$^2$ at 95% confidence level for $m_X < 70$ GeV/c$^2$. Figure 4 shows these results.

6. Conclusion

We have presented the latest measurements by the CDF collaboration of top quark intrinsic properties as well as direct searches for new physics in the top sector. The large number of top quark events analyzed, of the order of several thousands, allows stringent checks of the standard model predictions. Many of these results will be updated with the final CDF dataset.
