Abstract

Mineral based amelioration has been used for decades but Indian agriculture is seeking new alternative potentialized source for soil amendment to feed the soil without jeopardizing the sustainability and fertility of soil. A variety of mineral types are commonly used to amend contaminated soils, with different modes of molecular-scale sequestration. Natural zeolite with this prospective exhibited a much higher capacity to ameliorate ill soils through adsorption, cation exchange capacity catalyst and dehydration capacities than either sawdust or other cleaning sources. Zeolites are, therefore, used as a promoter for better crop production and improving soil health by enhancing the value of fertilizers, retaining valuable nutrients as well as improving the quality of resulting manures.

Keywords: Zeolite; Amelioration; Soil

Introduction

Soil amelioration describes any substances added to the soil to improve or modify its qualities and the conditions including physical, chemical, and biological conditions. Such an amended soil is a conditioned and a fertilized one. However, the selection of amendment may depend upon the degree of soil degradation, its composition and the climate etc. A suitable amendment to a situation may not be useful in other conditions [1]. In amelioration techniques of soil, various amendments particularly the inorganic amendments such as gypsum, lime, zeolites, altered rocks, ceramic, perlite, ash, slag, zeolite, pyrites, dolomite, calcined clay, etc. are used. Amongst, zeolitic represents a special niche in this category. There are about 40 identified natural zeolites [2] and more than 150 zeolites have been synthesized. The aim of any in-situ amendment technologies is to sequester and stabilize contaminants in soils or sediments in order to reduce their ability to partition to water or biota, and bring the physico-chemical environment of soil in order to provide most supportive conditions for plant growth and microbial actions. Zeolites are hydrated aluminosilicate minerals made from interlinked tetrahedra of alumina (AlO4) and silica (SiO4). They are solid with a relatively open, three-dimensional crystal structure built from the element’s aluminum, oxygen, and silicon, with alkali or alkaline-Earth metals (such as sodium, potassium, and magnesium) plus water molecules trapped in the gaps between them. Zeolites are crystalline, microporous aluminosilicates with relatively high cation exchange capacities (CECs), typically on the order of 250 cmolc/kg (Dyer 1988; Evans et al. 1990) and can retain water and negative charge capably to change heavy metals [3]. As a result, zeolites commonly are used commercially as adsorbents for removal of cations from wastewater (Jacobs and Forstner 1999; Yuan et al. 1999; Erdem et al. 2004; Inglezakis 2005). However, zeolites are used for various applications in industry, agriculture and environmental protection. Unlike other soil amendments (e.g. lime) zeolite does not break down over time but remains in the soil to improve nutrient retention. Therefore, its addition to soil will significantly reduce water and fertilizer costs by retaining beneficial nutrients in the root zone. The porous structure of natural zeolite helps to keep the soil aerated and moist as well as active for a long time. The most common zeolites in sedimentary deposits are analclime, chabazite, dinopentolite, erionite, heulandite, laumontite, mordenite, phillipsite, and wairakite, with clinoptilolite ranking first in abundance.

Occurrence of Zeolites Mineral in India

The use of natural zeolites has been continuously increasing over past years. The countries like Cuba, USA., Russia, Japan, Italy, South Africa, Hungary and Bulgaria have important resources of these minerals and production potentials [4]. In India zeolites in rocks were reported and mapped in the western part of...
Functioning of Zeolites in Soil

Zeolite acts as molecular sieves because of their specific three-dimensional structure [11]. Zeolites have a high porosity. Their sieving behavior in soil allows the selective penetration of particles of a certain size, dehydration and hydration of the crystals, the exchange of water to other molecules and the exchange of ions to different ones. In contrast to other known absorbents such as activated carbon or activated alumina, zeolites have a regular, replicable structure of internal pores and channels from 0.3 to 0.15nm [12].

Impact of amendment material (zeolite) on soil properties

The main objective of the amendments is to improve the use of the soil for agricultural purposes. The amendments may be natural or synthetic and by their origin organic or inorganic. Among amendments the inorganic ones are recommended, such as gypsum, lime, zeolites, altered rocks, ceramic, perlite, ash, slag, zeolite, pyrites, dolomite, calcined clay, etc. They contain a variable amount of nutrients, which can affect the pH.

Reducing soil bulk density and improving water retention capacity of soil

Bulk density of zeolite minerals can be as low as 0.8 Mg m⁻³ due to the porous nature [13]. Githinji et al. [14] reported application of zeolite (0.55-0.6mm) at a 15% (v/v) rate to sand (0.31mm) media decreased the bulk density from 1.67 to 1.56 Mg m⁻³ and increased the available water content by 2 times. Zeolite may hold water more than half of their weight due to high porosity of the crystalline structure. Amendment of sand with zeolite increases available water to the plants by 50% [15]. Zeolite works as a long-lasting water reservoir. Water withholds in small capillary for longer period, rewet the soil and improves root zone area through availing water during the peak hours. In prolonged moisture dry periods help plant to sustain turgidity within plant cell.

Improve pH and cation exchange capacity of soil. Pure zeolite materials usually have high CEC ranging from 220 to 570 cmolc kg⁻¹ [16]. Adding zeolites to a soil can increase the soil’s overall CEC and pH in most cases (Ming and Allen, 2001), thus soil’s nutrient holding capacity is enhanced. The large surface area of zeolitic material with slight alkalinity in nature acts as a buffering agent in soil. Zeolites, being of weakly alkaline reaction with the pH of around 8.0, can be combined with mineral fertilizers to maintain soil buffering and indirectly regulate soil pH thus reducing the need for lime application [4]. According to Colella (1999), the use of zeolitic volcanic tuff for acid soil conditioning led to effective pH buffering, neutralizes the hydrolytic and exchangeable acidity of soil.

Remediation of contaminated soil

The heavy metals pollution is increasing day by day due to heavy industrialization. Their excessive concentrations in soils often resulted from anthropogenic activities, such as the mining industry and processing of metal ores, waste incineration, road transport and the use of fertilizers and agrochemicals [17]. Heavy metals may persist in the soil for hundreds of years, which is associated with the risk of their inclusion in a trophic chain. For cleansing of these heavy pollutants, zeolite is a class of alkaline porous aluminosilicates with negatively charged crystal lattice, neutralized by the presence of exchanged cations in the structural cavities [18,19]. They are being proven as a good amending material for the improvement of soil quality. They diminish the solubility and thus the biological availability of metals: salts, complexes, as well as oxides and metal-carbonate precipitates are formed with zeolites [20,21]. Zeolite could be used an effective additive to control the odour [22], as they could adsorb the volatile

### Table 1: Chemical Composition of Indian Natural Zeolite [30].

| Indian Zeolite | SiO₂ | TiO₂ | MnO | CaO | K₂O | Al₂O₃ | Na₂O | Fe₂O₃ | MgO | P₂O₅ | H₂O |
|---------------|------|------|-----|-----|-----|-------|------|-------|-----|------|-----|
|               | 68.03| 0.21 | 0.01| 2.65| 2.26| 11.92 | 1.96 | 1.77  | 0.83| 0.06 | 10.25|

Enrichment of nutrient pool

Zeolites are recognized as “intelligent fertilizer” because they can exchange cations allowing nutrients such as nitrogen, calcium, iron, magnesium, potassium, and water to be available in the plant and be eliminated slowly [25]. The nutrients are released gradually, not only in the first year of the vegetation period but also in the second or the following years. The most important nutrients necessary for proper growth and development of plants, are nitrogen, potassium, calcium and magnesium. Among, clinoptilolite could make an excellent amendment material for sand by stabilizing the nitrate leaching. They affect not only the size of the crop but also its quality. Zeolites can retain nutrients in the topsoil, which are slowly and gradually leached from the soil. This allows the use of smaller doses of fertilizer, which is associated with a reduction in the cost of crop production (DeLuca DK, 1997).

Impact on microbial community

The removal of heavy metals in polluted areas is always been difficult because they persist in soils for very longer periods. The ability to mineralize organic matters is a key function of soil microorganisms, its sensitivity to metal contamination has always been a subject of many studies (Giller et al. 1998). Susana Sfechis [26] found the suitability of using natural zeolite (clinoptilolite) in agriculture, having a positive role in plant nutrition and microbial community stability. The treatment with 30% zeolite + 70% urea in spring barley causes a positive effect on microbiological community. A wide range of carbon sources were metabolised by the microorganisms found in the soil type (amino sugar, amino acids except L-arginine, all the carboxylic acid and the neutral sugars). In another study, nitrifying bacteria could not use the manure-ammonia in the zeolite due to small pore size [27]. Chander and Joergensen [28] concluded the zeolite effects on soil microbial populations and their activities are unknown. The microbial populations could respond to zeolite amendment in different ways, but further studies should be performed to understand better the zeolite effects on soil microbial properties.

Conclusion

Generally, Zeolites are naturally occurring aluminosilicates minerals that are used as source of plant nutrients and soil amendments. In agriculture, applications of zeolites can be used directly to soils as materials for growth media, mixed with manures during decomposition process, and for mixing with urea as slow release agent [29,30]. Zeolites are helpful for improving nutrients use efficiencies because they are responsible for reducing the immobilization and leaching losses of nutrients. Zeolites find many potential applications as it can be used as a soil amelioration for low cation exchange capacity of soils. It works as a mixing material for fertilizers, material for improvement of compost quality, material for water treatment of fishponds and in remediation of heavy metal contaminated soils. There is much more need of research efforts in India to exploit the potential of zeolites for the maintenance of soil health and productivity.
