Graph Isomorphism Completeness for Trapezoid Graphs

Asahi TAKAOKA\(^{(a)}\), Member

1. Introduction

Let \( G \) be an undirected simple graph, and let \( V(G) \) and \( E(G) \) be the vertex set and the edge set of \( G \), respectively. Two graphs \( G_1 \) and \( G_2 \) are said to be isomorphic if there is a bijection \( \phi : V(G_1) \to V(G_2) \) such that for every pair of vertices \( u, v \in V(G_1) \), \( uv \in E(G_1) \) if and only if \( \phi(u)\phi(v) \in E(G_2) \). Such \( \phi \) is called isomorphism from \( G_1 \) to \( G_2 \). We denote by \( G_1 \cong G_2 \) if \( G_1 \) and \( G_2 \) are isomorphic. The graph isomorphism problem asks whether two given graphs are isomorphic. Although the problem is in NP, it is not known to be NP-complete or polynomial-time solvable.

The graph isomorphism problem for particular classes of graphs has been investigated. See [2], [14], [18] for survey. The problem for a graph class is said to be GI-complete if it is polynomial-time equivalent to the problem for general graphs. For some graph classes, the problem is not known to be GI-complete or polynomial-time solvable. One of such graph classes is trapezoid graphs [14], [18], [19]. Trapezoid graphs are natural generalization of two well-known graph classes, interval graphs and permutation graphs. Although the problem can be solved in linear time for interval graphs [8] and for permutation graphs [3], [13], the complexity of the problem for trapezoid graphs has been open over a decade. We show in this paper that the problem is GI-complete for trapezoid graphs.

2. GI-Completeness for Trapezoid Graphs

Let \( L_1 \) and \( L_2 \) be two lines parallel to \( x \)-axis in the \( xy \)-plane. A graph \( G \) is called a trapezoid graph [4], [6] if for each vertex \( v \in V(G) \), there is a trapezoid \( T_v \) with parallel sides along \( L_1 \) and \( L_2 \) such that for any pair of vertices \( u, v \in V(G) \), \( uv \in E(G) \) if and only if \( T_u \) and \( T_v \) intersect. The set of trapezoids \( \{ T_v \mid v \in V(G) \} \) is called a trapezoid representation of \( G \).

The complement of a graph \( G \) is the graph \( \overline{G} \) such that \( V(\overline{G}) = V(G) \) and for any pair of vertices \( u, v \in V(G) \), \( uv \in E(\overline{G}) \) if and only if \( uv \notin E(G) \). Notice that for any two graphs \( G_1 \) and \( G_2 \), \( G_1 \cong G_2 \) if and only if \( \overline{G_1} \cong \overline{G_2} \). To prove the GI-completeness for trapezoid graphs, we consider the complements of trapezoid graphs, which are known as comparability graphs of partially ordered sets with interval dimension at most 2 [6].

A partially ordered set (poset) is a pair \( P = (X, \preceq) \), where \( X \) is a finite set and \( \preceq \) is a binary relation on \( X \) that is reflexive, antisymmetric, and transitive. We denote \( x \prec y \) if \( x \preceq y \) and \( x \neq y \). Two elements \( x, y \in X \) are said to be comparable in \( P \) if either \( x \prec y \) or \( y \prec x \), and are said to be incomparable otherwise. A subset \( Y \subseteq X \) is called a chain of \( P \) if any pair of elements of \( Y \) are comparable in \( P \). A chain of \( P \) is maximum if no other chain of \( P \) contains more elements than it. The height of \( P \) is the number of elements in a maximum chain of \( P \).

A poset \( P = (X, \preceq) \) is called an interval order if for each element \( x \in X \), there is an interval \( I_x = [r_x, l_x] \) on the real line such that for any pair of elements \( x, y \in X \), \( x \prec y \) if and only if \( r_x < l_y \). Here, we use \( < \) to denote the ordering of points on the real line, while \( < \) indicates the relation of a poset. The set of intervals \( \{ I_x \mid x \in X \} \) is called an interval representation of \( P \). A family of posets on the same set \( \{ P_i = (X_i, \preceq_i) \mid 1 \leq i \leq k \} \) is said to realize a poset \( P = (X, \preceq) \) if for any \( x, y \in X \), \( x \preceq y \) if and only if \( x_i \leq y_i \) for every \( i \in \{1, 2, \ldots, k\} \). The interval dimension of a poset \( P \) is the minimum number \( k \) of interval orders that realize \( P \).

A graph \( G \) is called a comparability graph of a poset \( P = (X, \preceq) \) if there is a bijection assigning each vertex \( v \in V(G) \) to an element \( x_v \in X \) such that for any \( u, v \in V(G) \), \( uv \in E(G) \) if and only if \( x_u \) and \( x_v \) are comparable in \( P \). We have the following, which is proved in the next section.

**Theorem 1.** The graph isomorphism problem is GI-complete for comparability graphs of posets with interval dimension 2 and height 3.

Since a graph is a comparability graph of a poset with interval dimension at most 2 if and only if it is the complement of a trapezoid graph [6], we have the following.

**Corollary 2.** The graph isomorphism problem is GI-
complete for trapezoid graphs.

Theorem 1 also gives a dichotomy for the graph isomorphism problem for comparability graphs of posets with interval dimension at most 2, since the problem can be solved in polynomial time if the height of the poset is at most 2.

**Proposition 3.** The graph isomorphism problem can be solved in \(O(n^2)\) time for comparability graphs of posets with interval dimension at most 2 and height at most 2, where \(n\) is the number of vertices of a graph.

**Proof.** The complements of comparability graphs of posets with interval dimension at most 2 and height at most 2 are circular-arc graphs with clique-cover number 2 [15], [16], for which the graph isomorphism problem is shown to be linear-time solvable by Eschen (as cited in [5]). Since it requires \(O(n^2)\) time to take the complements of graphs, we have the proposition.

Comparability graphs of posets with interval dimension at most 2 and height at most 2 are also known as 2-directional orthogonal ray graphs [12], [15]. See [18] for more information on the isomorphism of these graphs.

3. **Proof of Theorem 1**

The graph isomorphism problem is GI-complete for connected bipartite graphs [2]. We show a polynomial-time reduction from the problem for connected bipartite graphs to the problem for comparability graphs of posets with interval dimension 2 and height 3. The reduction is similar to that of [17], [19].

Let \(G\) be a connected bipartite graph with bipartition \((A, B)\) with \(|A|, |B| \geq 3\). We construct a graph \(H\) from \(G\)

- by replacing each edge \(e = ab\) of \(G\) with a vertex \(c_e\) together with two edges \(ac_e\) and \(bc_e\), and
- by adding edges so that the subgraph induced by \(A \cup B\) is a complete bipartite graph with bipartition \((A, B)\).

See Figs. 1(a) and 1(b) for example of the construction. The graph \(H\) can be constructed in polynomial time. Let \(C = \{c_e | e \in E(G)\}\), and we call \((A, B, C)\) the tripartition of \(H\).

We first show that two connected bipartite graphs \(G_1\) and \(G_2\) are isomorphic if and only if \(H_1\) and \(H_2\) are isomorphic.

Since it is obvious that \(H_1 \cong H_2\) if \(G_1 \cong G_2\), we show the other direction. Let \((A_i, B_i, C_i)\) be the tripartition of \(H_i\) for each \(i \in \{1, 2\}\). The degree of all vertices of \(C_i\) are 2 and the degree of the other vertices are at least 3, since \(|A_i|, |B_i| \geq 3\). Hence, an isomorphism from \(H_1\) to \(H_2\) maps the vertices of \(C_1\) to the vertices of \(C_2\) and maps the vertices of \(A_1 \cup B_1\) to the vertices of \(A_2 \cup B_2\). Since \(G_i\) can be obtained from \(H_i\) by deleting all edges between the vertices of \(A_i \cup B_i\), and by deleting each \(c \in C_i\) and adding an edge joining two vertices adjacent to \(c\), we conclude that \(G_1 \cong G_2\) if \(H_1 \cong H_2\).

We next show that \(H\) is the comparability graph of a poset with interval dimension at most 2 and height 3. Let \(P_H = (V(H), \preceq)\) be the poset obtained from \(H\) with tripartition \((A, B, C)\) such that \(a \prec b, a \prec c,\) and \(c \prec b\) for any \(a \in A, b \in B,\) and \(c \in C\). It is easy to verify that the relation \(\prec\) is transitive and the height of the poset \(P_H\) is 3.

Now, it suffices to show the interval representations of two interval orders \(P_1\) and \(P_2\) that realize \(P_H\). Let \(I_i(v) = \{v \in V(H) | v \text{ is the interval representation of } P_i\}\) for each \(i \in \{1, 2\}\). The interval \(I(v)\) for any \(v \in A \cup B\) is degenerated to the point \(p_i(v)\) in the representations. For any \(c \in C_i\), let \(l(c)\) and \(r(c)\) be the left and right end-point of \(I(c)\), respectively. We denote the interval representations by a series of points on the real line. Let \(o\) be the origin of the real line, and let \(A = \{a_1, a_2, \ldots, a_i\}\) and \(B = \{b_1, b_2, \ldots, b_j\}\). We place the points corresponding to the elements of \(A \cup B\) on the real line.
line such that
\[ p_1(a_1) < p_1(a_2) < \ldots < p_1(a_i) < o < p_1(b_1) < p_1(b_2) < \ldots < p_1(b_i) \]
and
\[ p_2(a_i) < p_2(a_{i-1}) < \ldots < p_2(a_1) < o < p_2(b_2) < p_2(b_{i-1}) < \ldots < p_2(b_1). \]

We can verify that \( a < b \) for any \( a \in A \) and \( b \in B \), any pair of elements of \( A \) are incomparable, and any pair of elements of \( B \) are incomparable.

Let \( c \in C \) be a vertex of \( H \) adjacent to \( a_i \in A \) and \( b_j \in B \). We place the end-points \( l_1(c) \) and \( r_1(c) \) such that
\[ p_1(a_i) < l_1(c) < p_1(a_{i+1}) \leq o \leq p_1(b_{j-1}) < r_2(c) < p_1(b_j) \]
and place the end-points \( l_2(c) \) and \( r_2(c) \) such that
\[ p_2(a_i) < l_2(c) < p_2(a_{i+1}) \leq o \leq p_2(b_{j+1}) < r_2(c) < p_2(b_j), \]
where \( p_1(a_{i+1}) = p_1(b_0) = o \) and \( p_2(a_0) = p_2(b_{i+1}) = o \). When more than one vertex of \( C \) is adjacent to a vertex \( a_i \in A \) (resp. \( b_j \in B \)), we place the left (resp. right) end-points any order on the intervals \([p_1(a_i), p_1(a_{i+1})]\) and \([p_2(a_i), p_2(a_{i+1})]\) (resp. on the intervals \([p_1(b_{j-1}), p_1(b_j)]\) and \([p_2(b_{j-1}), p_2(b_j)]\)). It can be verified that \( a_i < c < b_j \) and \( c \) is incomparable to any other element of \( A \cup B \). Moreover, any pair of elements of \( C \) are incomparable, since any interval corresponding to an element of \( C \) contains the origin \( o \). Hence, the interval orders \( P_1 \) and \( P_2 \) realize \( P_{H_0} \) and we have Theorem 1.

Figure 1(c) shows the interval representations of the pair of posets that realizes the poset \( P_{H_0} \) in Fig. 1(b). The trapezoid representation of the complement of \( H_0 \) is also shown in Fig. 1(c).

4. Concluding Remarks

We show in this paper that the graph isomorphism problem is GI-complete for trapezoid graphs. Since the problem can be solved in linear time for interval graphs [8] and for permutation graphs [3, 13], it is an interesting open question to determine the complexity of the problem for graph classes between trapezoid graphs and interval graphs or between trapezoid graphs and permutation graphs. Examples of such graphs are parallelogram graphs [1, 7, 11], triangle graphs [4, 9] and simple-triangle graphs [4, 10]. Other open problems can be found in [14, 18].
