LOG SMOOTHNESS AND POLYSTABILITY OVER VALUATION RINGS

KARIM ADIPRASITO, GAKU LIU, IGOR PAK, AND MICHAEL TEMKIN

Abstract. Let $\mathcal{O}$ be a valuation ring of height one of residual characteristic exponent $p$ and with algebraically closed field of fractions. Our main result provides a best possible resolution of the monoidal structure $M_X$ of a log variety $X$ over $\mathcal{O}$: there exists a log modification $Y \to X$ such that the monoidal structure of $Y$ is polystable. In particular, if $X$ is log smooth over $\mathcal{O}$ then $Y$ is polystable. As a corollary we deduce that any log variety over $\mathcal{O}$ possesses a polystable alteration of degree $p^n$. The core of our proof is a subdivision result for polyhedral complexes satisfying certain rationality conditions.

1. Introduction

1.1. Motivation. The original motivation for undertaking this project was the following question: can any log smooth scheme (or formal scheme) over a valuation ring $\mathcal{O}$ of height one be modified to a polystable one? It seems that the expert community did not have a clear consensus if the answer should be yes or no, though at least few experts hoped the answer might be positive. Our main result provides the positive answer to the question. Moreover, we develop the theory in the more general form of “resolving the monoidal structure” of an arbitrary log variety over $\mathcal{O}$ (by which we essentially mean log schemes of finite over $\mathcal{O}$, see §5.2.2). In particular, our main result extends the absolute monoidal resolution of fine log schemes of Gabber, see [IT14, Theorem 3.3.16], to this relative (and non-fine) case.

1.2. Background. To explain what the above question means, why it is important, and where it comes from we shall recall some history.

1.2.1. Semistable modification. To large extent, toroidal geometry and related combinatorial methods in algebraic geometry originate from the seminal work [KKMS73]. Its aim was to prove the semistable reduction (or modification) theorem over a discrete valuation ring $\mathcal{O}$ of residual characteristic zero: if $X$ is an $\mathcal{O}$-variety with smooth generic fiber $X_\eta$ then there exists a modification $X' \to X$ such that $X'_\eta = X_\eta$ and $X'$ is semistable. Recall, that the latter means that étale-locally $X'$ admits an étale morphism to standard semistable varieties of the form

$$\text{Spec}(\mathcal{O}[t_0, \ldots, t_n]/(t_0 \ldots t_l - \pi)),$$

Date: June 26, 2018.

Key words and phrases. Logarithmic smoothness, polystability, mixed subdivisions, valuation rings, Berkovich analytic spaces.

where \( \pi \in \mathcal{O} \) (sometimes one also wants \( \pi \) to be a uniformizer). The proof goes in two steps: (1) using Hironaka’s theorem one reduces to the case when \( X \) is toroidal over \( \mathcal{O} \), (2) for toroidal \( \mathcal{O} \)-varieties the question is translated to geometry of polytopes with rational vertices and is then resolved by combinatorial methods. Certainly, part (1) is much deeper, but, once Hironaka’s theorem is available, the reduction is easy. So, [KKMS73] is mainly occupied with constructing the translation (that is, building foundations of toroidal geometry, see [KKMS73, Chapters I and II]), and solving the (still rather difficult) combinatorial problem about subdividing polytopes with rational vertices into simplices of especially simple form, see [KKMS73, Chapter III].

1.2.2. Log geometry. This work is written within the framework of log geometry, which nowadays gradually subsumes toroidal geometry. In this setting the above strategy receives the following natural interpretation: first one resolves \( X \) obtaining a log smooth variety \( Y \) over \( \mathcal{O} \), and then one improves the monoidal structure of \( Y \) by log smooth modifications only (e.g. log blow ups). In particular, we will work with log structures which are finitely generated over the log structure of \( \mathcal{O} \), but are not fine.

1.2.3. Classical combinatorics. In toric and toroidal geometries, combinatorics is used to model various properties of certain varieties. In a nutshell, on the side of functions one considers rational polyhedral cones \( \sigma \) in a vector space \( M \) with a fixed lattice \( \Lambda \), and on the geometric side one considers dual cones \( \sigma^* \) in \( N = M^* \) and fans obtained by gluing such cones. If one works over a discrete valuation ring \( \mathcal{O} \), then any uniformizer \( \pi \) induces a canonical element \( v_\pi \in \Lambda \) and one can also restrict to the hyperplane \( N_1 \) given by \( v_\pi = 1 \). In this way, one passes from cones to polytopes. Finally, one can also use the equivalent language of toric monoids \( P \), their spectra \( \text{Spec}(P) \) and fans obtained by gluing the latter. Then \( \sigma \) and \( \sigma^* \) correspond to \( P = \sigma \cap \Lambda \) and \( \text{Spec}(P) \). The latter language is essentially due to Kato, and it is convenient for applications to log geometry of fine schemes.

1.2.4. Limits of semistability. Assume now that \( \mathcal{O} \) is an arbitrary valuation ring of height one. In addition, we assume that its fraction field \( K \) is algebraically closed. (Since semistable reduction is studied up to finite extensions of \( K \), this does not really restrict the generality.) In particular, we can view the group of values of \( K \) as a \( \mathbb{Q} \)-vector subspace \( V \) of \( \mathbb{R} \). Semistability over \( \mathcal{O} \) can be studied in two similar contexts: (1) for schemes of finite type over \( \mathcal{O} \), (2) for formal schemes over \( \mathcal{O} \), if the latter is complete. Let \( X \) be a (formal) \( \mathcal{O} \)-scheme of finite type with smooth generic fiber \( X_\eta \). It was known to experts for a long time that semistable modification of \( X \) might not exist when \( \dim(X_\eta) > 1 \) and \( \dim_{\mathbb{Q}}(V) > 1 \) (for example, see [Tem10, Remark 3.4.2]).

Here is a quick explanation. Combinatorics of log smooth \( \mathcal{O} \)-schemes can be encoded by \( (\mathbb{Z}, V) \)-polytopes, or simply \( V \)-polytopes, introduced by Berkovich in [Ber99] (loc.cit. uses exponential notation). These are polytopes in \( \mathbb{R}^n \) whose vertices are in \( V^n \) and edge slopes are rational. The main combinatorial result of [KKMS73] describes triangulations of such polytopes when \( \dim_{\mathbb{Q}}(V) = 1 \). However, if \( \dim_{\mathbb{Q}}(V) > 1 \) then no triangulation might exist even in dimension 2, see also Section 4.1.4 for a specific example.
1.2.5. **Polystable reduction conjecture.** Polystable (formal) schemes over $\mathcal{O}$ were introduced by Berkovich in [Ber99, Section 1]; étale locally they are products of semistable ones. The above example shows that over a general base the best one can hope for is a polystable modification. In fact, it was conjectured in [AK00, Conjecture 0.2] (the terminology is different!) and [Tem10, Remark 3.4.2] that polystable modification does exist. Over $\mathcal{O}$ the conjecture reads as follows:

**Conjecture 1.2.6.** Let $\mathcal{O}$ be as above and assume that $X$ is a flat $\mathcal{O}$-scheme of finite type whose generic fiber $X_\eta$ is smooth. Then there exists a modification $Y \rightarrow X$ such that $Y_\eta = X_\eta$ and $Y$ is polystable over $\mathcal{O}$.

1.3. **Main results.**

1.3.1. **The monoidal resolution theorem.** As in the case of a DVR, it is natural to attack Conjecture 1.2.6 in two steps: (1) find a modification $Y \rightarrow X$ with a log smooth $Y$, (2) make the log structure of $Y$ polystable using log modifications. Similarly to [KKMS73] in the case of DVR’s, this paper establishes step (2), which is the combinatorial part of the problem. In fact, Theorem 5.2.16 even proves that the log structure of an arbitrary log variety over $\mathcal{O}$ can be made polystable by a log modification.

**Remark 1.3.2.** (i) Our result provides a good evidence to expect that polystable modification always exists, at least, there are no combinatorial obstacles and the question reduces to establishing step (1). See, also §1.3.3 below.

(ii) In addition, our result highlights importance of the class of polystable formal schemes for Berkovich geometry.

1.3.3. **Application to polystable modification/alteration.** In general, question (1) is very hard, at the very least, not easier than resolution of singularities and semistable reduction in positive characteristic. However, if the residual characteristic is zero then an affirmative answer immediately follows from the semistable reduction of Abramovich-Karu [AK00, Theorem 2.1], and in general this can be achieved by the $p$-alteration theorem [Tem17, 1.2.9] (which improves on results of de Jong, Gabber and Illusie-Temkin). As a corollary we will prove in Theorem 5.2.18 that any log variety $X$ over $\mathcal{O}$ possesses an alteration $X' \rightarrow X$ of degree $p^n$, where $p$ the residual characteristic exponent of $\mathcal{O}$, such that $X'$ is polystable over $\mathcal{O}$. In particular, in the equal characteristic zero case, polystable modification does exists.

**Remark 1.3.4.** (i) Even in the equal characteristic zero case, the weak point of the cited results and our Theorem 5.2.18 is that the modification $X' \rightarrow X$ modifies the generic fiber $X_\eta$ even when it is smooth. In particular, it does not provide polystable models of varieties over $K$, whose existence still remains a (now very plausible) conjecture. However, it seems very probable that this finer problem will be solved soon by a new logarithmic desingularization algorithm developed in [ATW17] (so far, for log varieties over a field). This would settle Conjecture 1.2.6 in the equal characteristic zero case.

(ii) We shall also mention that in [For16, Theorem 1.7] Patrick Forréd claims a strong form of polystable reduction over valuation rings of height $h$ with group of values $\mathbb{N}_h$, although we were not able to verify all details.

1.3.5. **Combinatorics of log varieties over $\mathcal{O}$.** As in the classical case, there are several equivalent ways to describe combinatorics of toric and toroidal geometries.
over $\mathcal{O}$. In fact, we extend all classical approaches outlined in §1.2.3 to this case, and prove their equivalence. On the side of functions, we introduce categories of $R$-toric monoids, where $R = V \cap \mathbb{R}_{\geq 0}$, and $V$-special cones, and establish their equivalence in Theorem 3.1.4. On the geometric side, we introduce the categories of $R$-toric fans, $V^\perp$-special cone complexes, and $V$-affine polyhedral complexes, establish their equivalence in Theorem 3.3.11, and prove that the latter preserves various geometric properties, such as simpliciality and polystability, see §3.4.

Remark 1.3.6. (i) We decided to work out foundations in such detail because each approach has advantages of its own. In particular, fans are most naturally related to monoidal structure of log varieties over $\mathcal{O}$, the language of $V$-affine polytopes is most convenient to prove the subdivision theorem, and the two theories are naturally compared through $V$-special and $V^\perp$-special cones. Also, we expect that these foundations will be useful for further research of (formal) varieties over $\mathcal{O}$.
(ii) Gubler-Soto used $V^\perp$-special complexes in [GS15, Section 4] to study toric $\mathcal{O}$-varieties. In loc.cit. they were called “$V$-admissible fans”.
(iii) The language of $V$-affine polytopes (and its analogue for PL spaces) was used by Berkovich to describe a natural structure on skeletons of analytic spaces over $\mathcal{O}$.

1.3.7. Future directions. In [AK00] Abramovich and Karu conjectured that any morphism $P \to Q$ of rational polyhedral complexes can be made a polystable one by an appropriate subdivision of $P$ and $Q$ and altering the lattice of the base, see [AK00, Section 8] for details. In fact, our main combinatorial result, Theorem 4.5.2, can be viewed as a local on the base version of that conjecture, and the two problems are tightly related. In particular, Dan Abramovich pointed out that the first stage of our construction, existence of a polysimplicial subdivision, was established in the global setting in [AR02]. We expect, that the conjecture of Abramovich-Karu can be treated by our method, but this will be worked out in detail elsewhere.

1.4. Structure of the paper. Finally, let us give an overview of the paper. In Section 2 we recall basic facts about monoids and their spectra. The results are rather standard but hard to find in the literature, especially in the generality of monoids which are not finitely generated. In §2.3 we introduce $R$-toric monoids over a sharp valuative monoid $R$ of height one and $R$-toric fans obtained by gluing spectra of $R$-toric monoids. This extends Kato’s approach to combinatorics of fine log schemes to log varieties over $\mathcal{O}$.

In Section 3 we study the related cone and polyhedral complexes, and prove the equivalence theorems mentioned in §1.3.5. This extends the combinatorics of the classical toroidal/toric geometry to the case of $\mathcal{O}$-varieties.

Section 4 is devoted to the proof of our main combinatorial result, Theorem 4.5.2 on polystable subdivisions of $V$-affine polytopes, and then extends it to polyhedral complexes.

Finally, in Section 5 we apply the results of §§2–4 to study log varieties over $\mathcal{O}$. As a preparation, we prove in Theorem 5.2.13 that any log variety $X$ possesses a log modification $Y \to X$ such that the log structure of $Y$ is Zariski. Then, we show that any Zariski log variety possesses a fan, and a polystable subdivision of fan constructed in the earlier sections induces the desired polystable resolution of the log structure of $X$. 
**Acknowledgments.** We would like to thank D. Abramovich and W. Gubler for valuable remarks and suggesting to apply our method to altered resolution of log varieties over $\mathcal{O}$. We followed this suggestion by proving Theorem 5.2.18.

2. Monoschemes and fans over valuative monoids

In this section we collect needed material on integral monoids and their spectra. Some results are perhaps well known to experts, but miss in the literature.

2.1. Monoids.

2.1.1. *Conventiones.* A monoid in this paper means a commutative monoid $M = (M, +)$. As usually, $M^\times$ is the subgroup of units, and $M/M^\times$ is the sharpening of $M$. We will use notation $M \oplus \mathbb{N}^n = M[t_1, \ldots, t_n] = M[t]$, where $t = (t_1, \ldots, t_n)$ is the basis of $\mathbb{N}^n$.

Recall that $M_{\text{int}}$ is the image of $M$ in its Grothendieck group $M^{\text{gp}}$, and $M$ is integral if $M = M_{\text{int}}$. Although we will mainly work within the category of integral monoids, we will use full notation to avoid confusions. For example, an integral pushout will be denoted $(M_1 +_M M_2)^{\text{int}}$.

2.1.2. Splittings. Studying of toric monoids easily reduces to the sharp case because units can be split off. In general, one should be more careful.

**Lemma 2.1.3.** An integral monoid $P$ splits as $P = P^\times \oplus \overline{P}$ if and only if the associated short exact sequence of abelian groups $P^\times \to P^{\text{gp}} \to \overline{P}^{\text{gp}}$ splits.

**Proof.** The direct implication is clear. Conversely, if $\phi: \overline{P}^{\text{gp}} \hookrightarrow P^{\text{gp}}$ splits the sequence, then $P = P^\times \oplus \phi(\overline{P})$ since $P$ is the preimage of $\overline{P}$ under $P^{\text{gp}} \to \overline{P}^{\text{gp}}$. □

**Remark 2.1.4.** If $P$ is saturated then $\overline{P}^{\text{gp}}$ is torsion-free. In general, this is not enough for splitting, but in the toric case $\overline{P}^{\text{gp}}$ is finitely generated, and hence free.

Another useful way to simplify a monoid $P$ is to split off a free part. We say that an element $t \in P$ is prime if the ideal $(t) = P + t$ is prime. The following lemma is obvious.

**Lemma 2.1.5.** An element $t \in P$ is prime if and only if $P$ splits as $P = Q[t]$. In addition, $Q = P \setminus \{t\}$, so the splitting is uniquely determined by $t$.

2.1.6. Finite presentation. An $M$-monoid $N$ is a monoid provided with a homomorphism $\phi: M \to N$. We say that $N$ is finitely generated over $M$ if it is generated over $\phi(N)$ by finitely many elements. In other words, $\phi$ can be extended to a surjective homomorphism $\psi: M[t_1, \ldots, t_n] \to N$. If, in addition, one can choose $\psi$ defined by an equivalence relation generated by finitely many relations $f_i = g_i$ with $f_i, g_i \in M[t]$, then we say that $N$ is of finite presentation over $M$.

**Lemma 2.1.7.** Assume that $\phi: M \to N$ is an injective homomorphism of integral monoids, and assume that $N$ is finitely generated over $M$. Then $N$ is finitely presented over $M$ as an integral monoid, in the sense that there exists a finitely presented $M$-monoid $L$ such that $L^{\text{int}} = N$.

**Proof.** Choose a presentation $N = M[t_1, \ldots, t_n]/R$, where $R$ is generated by relations $f_i = g_i$ for $i \in I$. Let $R^{\text{gp}}$ be the subgroup of $M[t]^{\text{gp}} = M^{\text{gp}} \oplus \mathbb{Z}^n$ generated by the elements $f_i - g_i$. Since $\phi$ is injective, $R^{\text{gp}} \cap M^{\text{gp}} = 0$ and hence there exists a finite subset $I' \subseteq I$ such that $R^{\text{gp}}$ is generated by the elements $f_i - g_i$ with $i \in I'$. 

Let $R'$ be the equivalence relation generated by equalities $f_j = g_j$ with $i \in I'$. Then $L = M[t_1, \ldots, t_n]/R'$ admits a surjective map $L \to N$ inducing an isomorphism $L^{\text{gp}} = N^{\text{gp}}$. In particular, $L^{\text{int}} = N$. □

2.1.8. Approximation. A finitely presented $M$-monoid $N$ is defined already over a fine submonoid of $M$. This is a classical result in the case of rings, and the case of monoids is similar:

**Lemma 2.1.9.** Let $f: M \to N$ be as in Lemma 2.1.7 and let $\{M_i\}_{i \in I}$ be the family of fine submonoids of $M$. Then there exist $i \in I$ and a finitely generated integral $M_i$-monoid $N_i$ with an isomorphism $(N_i \oplus M, M)^{\text{int}} = N$. Moreover, if $N'_i$ is another such $M_i$-monoid then there exists $j \geq i$ and an isomorphism $(N_i \oplus M, M_j)^{\text{int}} = (N'_i \oplus M, M_j)^{\text{int}}$ compatible with $(N_i \oplus M, M)^{\text{int}} = N = (N'_i \oplus M, M)^{\text{int}}$.

**Proof.** By Lemma 2.1.7 we have that $N = (M[t_1, \ldots, t_n]/R)^{\text{int}}$, where $R$ is generated by equalities $f_j = g_j$ with $1 \leq j \leq n$ and $f_j, g_j \in M[t]$. The elements $f_j, g_j$ lie in $M_i[t]$ for a large enough $i$. The equalities $f_j = g_j$ generate an equivalence relation $R_i$ on $M_i[t]$, and $N_i = (M_i[t]/R_i)^{\text{int}}$ is as required. If $N'_i = (M_i[x_1, \ldots, x_n]/R'_i)^{\text{int}}$ is another such $R_i$-monoid, then we have equalities $t_k = m'_k + \sum_i a_{kj}x_j$ and $x_j = m''_j + \sum_i b_{kj}t_k$ in $N$ with $m'_k, m''_j \in M$. Therefore, we can take any $M_j$ containing the elements $m'_1, m'_n, m''_1, \ldots, m''_n$. □

2.1.10. Valuative monoids. By a valuative monoid we mean an integral monoid $M$ such that $M^{\text{gp}} = M \cup (-M)$. Let us list a few basic facts. Justification is analogous to the parallel theory of valuation rings, so we only indicate it. Setting $m_1 \geq m_2$ if $m_1 - m_2 \in M$ defines an order on $M^{\text{gp}}$, and $m_1 \sim m_2$ if and only if $m_1 - m_2 \in M^\times$. In particular, $M^{\text{gp}} = M^{\text{gp}}/M^\times$ acquires a total order and the homomorphism $\nu: M \to M^{\text{gp}}$ can be viewed as a valuation. In fact, an integral monoid $M$ is a valuative monoid if and only if $M$ is of the form $A_{\geq 0}$, where $A$ is a totally ordered abelian group and $A_{\geq 0} = \{a \in A | a \geq 0\}$. Ideals of a valuative monoid $M$ are totally ordered by inclusion, and prime ideals correspond to convex subgroups $H \subseteq M^{\text{gp}}$ via $H \mapsto M \setminus \nu^{-1}(H)$. A valuative monoid is of height $n$ if it has exactly $n$ non-empty prime ideal, and this happens if and only if $M^{\text{gp}}$ is of height $n$. Equivalently, $M^{\text{gp}}$ admits an ordered embedding into $R^l$ if and only if $l \geq n$.

2.2. Fans, monoschemes, and subdivisions.

2.2.1. Convention. We will use the same definition as in [IT14, Section 2.1], but applied to arbitrary integral monoids, which do not have to be fine. So, throughout this paper a monoscheme is a monoidal space $X = (X, M_X)$ locally of the form $\text{Spec}(M)$ with an integral monoid $M$. A fan is a monoidal space which is locally isomorphic to the sharpening $\overline{X} = (X, \overline{M_X})$ of a monoscheme. We will write $\text{Spec}(M)$ instead of $\text{Spec}(\overline{M})$, it depends only on $\overline{M}$.

**Remark 2.2.2.** (i) Clearly, $\overline{X}$ and the morphism of monoidal spaces $\overline{X} \to X$ depend functorially. In some aspects, the sharpening morphism $\overline{X} \to X$ can be viewed as an analog of the reduction morphisms $\text{Red}(X) \to X$ in the theory of schemes. In particular, both only replace the structure sheaf by its quotient.
(ii) In the theory of schemes, some types of morphisms to Red(\(X\)) can be lifted canonically to morphisms to \(X\). For example, this is the case for the class of étale morphisms. In the theory of fans and monoschemes, we will now introduce a class of birational morphisms, which possesses a similar lifting property from sharpenings.

2.2.3. Morphisms of finite type. A morphism \(f: Y \to X\) of monoschemes or fans is called locally of finite type if locally it is of the form \(\text{Spec}(N) \to \text{Spec}(M)\) or \(\text{Spec}(N) \to \text{Spec}(M)\) with \(N\) finitely generated over \(M\). We say that \(f\) is of finite type if it is quasi-compact and locally of finite type.

Remark 2.2.4. (i) The definition we gave is local. We will not need this, but it is easy to see that in the affine case it suffices to check the global sections: \(\text{Spec}(N) \to \text{Spec}(M)\) is of finite type if and only if \(N\) is finitely generated over \(M\).

(ii) In view of Lemma 2.1.7, in the category of (integral) monoschemes there is no need to introduce a finer class of finitely presented morphisms.

2.2.5. Birational morphisms of monoschemes. Let \(f: Y \to X\) be a morphism of monoschemes. We say that \(f\) is birational if it induces a bijection between the sets of generic points and \(f^\#: M_{X,f(y)}^{\text{gp}} \sim M_{Y,y}^{\text{gp}}\) for any point \(y \in Y\).

Remark 2.2.6. Since \(M_{X,Y}^{\text{gp}}\) and \(M_{Y,Y}^{\text{gp}}\) are locally constant, it suffices to check that \(f^\#\) are isomorphisms only for generic points \(\eta \in Y\). Since \(M_{X,Y}^{\text{gp}} = M_{Y,Y}^{\text{gp}}\), we see that \(f\) is birational if and only if it induces an isomorphism of the monoschemes of generic points of \(Y\) and \(X\).

2.2.7. Birational morphisms of fans. Passing to fans preserves only the surjectivity of the maps \(f^\#\), so we say that a morphism \(f: Y \to X\) of fans is birational if the maps \(f^\#\) are surjective for any \(y \in Y\).

Remark 2.2.8. In the case of fans, one has to check the surjectivity at all closed points of \(Y\), while it is vacuously true for generic points \(\eta\) because \(M_\eta = 0\).

2.2.9. The lifting property. We will now prove that birational morphisms of fans lift to monoschemes uniquely, and characterise this lifting by a universal property.

Lemma 2.2.10. Let \(X\) be a monoscheme with associated fan \(\overline{X}\) and let \(g: Z \to \overline{X}\) be a birational morphism of fans, then

(i) There exists a birational morphism \(f: Y \to X\) such that \(f^\# = g\), and it is unique up to unique isomorphism. In addition, \(f\) is of (locally) finite type if and only if \(g\) is of (locally) finite type.

(ii) For any morphism of monoschemes \(T \to X\), the natural map \(\text{Mor}_X(T,Y) \to \text{Mor}_{\overline{X}}(T,\overline{Y})\) is bijective.

Proof. We should construct \(f\) and \(h\) in the right diagram below and prove that they are unique. It suffices to do this locally on \(X\), \(Z\) and \(T\), since the local liftings then glue by the uniqueness. Also, the condition on being of finite type can be checked locally because the sharpening morphisms are homeomorphisms.

Thus, assuming that \(X = \text{Spec}(P)\) and \(T = \text{Spec}(L)\) are affine, and \(g\) corresponds to a homomorphism \(\lambda: \overline{P} \to R\) such that \(\overline{P}^{\text{gp}} \to R^{\text{gp}}\), we can switch from the left
The induced map \( \varphi: P^{gp} \to R^{gp} \) is surjective, hence setting \( Q = \varphi^{-1}(R) \) we obtain a homomorphism \( \phi: P \to Q \) such that \( P^{gp} = Q^{gp} \) and \( \varphi = \lambda \). In particular, \( f: Y = \text{Spec}(Q) \to X \) is birational and \( g = \overline{f} \). In addition, it is clear that \( Q \) is finitely generated over \( P \) if and only if \( R \) is finitely generated over \( P \).

Furthermore, we claim that given this \( \phi \), there is a unique \( \psi: Q \to L \) making the left diagram commutative. Indeed, since \( Q \subseteq Q^{gp} = P^{gp} \), it suffices to check that \( \rho^{gp}(Q) \) lies in \( L \). Therefore, it suffices to check that \( P^{gp} \to \overline{L}^{gp} \) takes \( Q \) to \( L \), and the latter is clear since \( Q^{gp} = P^{gp} \to \overline{L}^{gp} \) is compatible with the homomorphism \( Q \to R \to \overline{L} \).

It remains to show that \( \phi \) is unique. If \( \phi': P \to Q' \) is another such homomorphism, then applying (ii) to \( L = Q' \) and the identity \( \overline{Q} = R = \overline{Q} \), we obtain a canonical map \( Q' \to Q \). Its inverse, \( Q' \to Q \) is obtained in the same way, hence \( \phi \) is unique. □

Since the sharpening functor preserves birationality, Lemma 2.2.10(i) implies the following result.

**Corollary 2.2.11.** For any monoscheme \( X \) the sharpening functor induces an equivalence between the categories of birational morphisms \( Y \to X \) and birational morphisms \( Z \to \overline{X} \). This equivalence preserves the property of morphisms to be of (locally) finite type.

2.2.12. **Subdivisions.** A morphism of fans or monoschemes \( f: Y \to X \) is called a subdivision (resp. a partial subdivision) if it is birational, of finite type, and the following condition is satisfied:

\[ (S) \text{ For any valuative monoid } R \text{ and the associated monoscheme } S = \text{Spec}(R), \text{ the map } \lambda_S: \text{Mor}(S,Y) \to \text{Mor}(S,X) \text{ is bijective (resp. injective).} \]

**Remark 2.2.13.**

(i) Kato used in [Kat94, Section 9] the notions of proper subdivisions and subdivisions. Our terminology follows [GR13, Section 3.5], which seems to be more precise. These notions are analogous to the notions of separated birational and proper birational morphisms of schemes, with \( (S) \) being an analog of the valuative criteria.

(ii) In [Kat94, Section 9] Kato considered the case of fine fans, and then it sufficed to consider the valuative monoid \( \mathbb{N} \) only. This is analogous to the fact that for noetherian schemes it suffices to consider traits in the valuative criteria.
Lemma 2.2.14. In the definition of (partial) subdivisions one can replace condition (S) by the following condition (S): For any sharp valuative monoid $R$ and the associated fan $\overline{S} = \text{Spec}(R)$, the map $\lambda_{\overline{S}}: \text{Mor}(\overline{S}, Y) \to \text{Mor}(\overline{S}, X)$ is bijective (resp. injective).

**Proof.** This follows easily from the following claim: if $M \to N$ is a homomorphism of monoids such that $M^{\text{gp}} = N^{\text{gp}}$, and $M \to R$ is a homomorphism to a valuative monoid, then $M \to R$ factors through $N$ if and only if $M \to R$ factors through $N$. The latter is true for any integral monoid $R$. Indeed, $M^{\text{gp}} \times_{\text{gp}} R = M^{\text{gp}} \times_{\text{gp}} \overline{R}$ because $R = R^{\text{gp}} \times_{\text{gp}} \overline{R}$, and it remains to use that $M \to R$ factors through $N$ if and only if $N \subseteq M^{\text{gp}} \times_{\text{gp}} R$, and similarly for $M \to R$. □

Corollary 2.2.15. Let $X$ be a monoscheme with associated fan $\overline{X}$. Then the sharpening functor induces equivalence between the categories of subdivisions (resp. partial subdivisions) of $X$ and $\overline{X}$.

**Proof.** By Corollary 2.2.11 we should only prove the following claim: assume that $f: Z \to X$ is birational, then $f$ is a subdivision (resp. a partial subdivision) if and only if $\overline{f}$ is. The claim, in its turn, follows from Lemma 2.2.14 and the obvious observation that, given a fan $F$, any morphism $F \to Z$ factors uniquely through $\overline{F}$, that is, $\text{Mor}(F, Z) = \text{Mor}(F, \overline{Z})$. □

2.2.16. **Local isomorphisms.** Let $f: Y \to X$ be a morphism of monoschemes (resp. fans). We say that $f$ is a local isomorphism if it is of finite type and for any $y \in Y$ with $x = f(y)$ one has that $M_{X,x} = M_{Y,y}$ (resp. $M_{X,x} = M_{Y,y}$). As in the case of schemes, the following result holds:

Lemma 2.2.17. Assume that $f$ is a local isomorphism between monoschemes or fans. Then $f$ is birational, and $f$ is a subdivision (resp. a partial subdivision) if and only if it is bijective (resp. injective).

**Proof.** For concreteness, we consider only the case of monoschemes. Let $R$ be a valuative monoid. Then $S = \text{Spec}(R)$ is a local monoscheme with closed point $s$, and giving a morphism $f: S \to X$ equivalent to choosing a point $x = f(s)$ and giving a local homomorphism $M_{X,x} \to R$. In addition, as in the case of rings, using Zorn’s lemma it is easy to prove that for any point $x \in X$ there exists a local homomorphism $M_{X,x} \to R$ where $R$ is a valuative monoid. (In addition, one can achieve that $R^{\text{gp}} = M_{X,x}^{\text{gp}}$.) The lemma follows. □

2.2.18. **Blow ups.** Let $X$ be a monoscheme and $I \subseteq \mathcal{O}_X$ a quasi-coherent sheaf of ideals. Then there is a universal morphism $f: X' \to X$ such that $f^*(I)$ is invertible (that is, locally generated by a single element). One calls $X'$ the blow up of $X$ along $I$ and denotes it $X_I$, see [Ogu18, Theorem II.1.7.2]. The theory of blow ups of monoschemes is developed in [Ogu18, Section II.1.7] and it is simpler than its scheme-theoretic analogue. Note also that $M_X$ and $\overline{M}_X$ have the same ideals and hence applying the sharpening functor one obtains a similar theory for fans. For example, $\overline{f}: \overline{X}' \to \overline{X}$ is the universal morphism of fans such that the pullback of $IM_X$ is invertible.

Let us list a few simple facts from [Ogu18, Section II.1.7]. Blow ups form a filtered family, since $X_{I \times J} = X_{I+J}$. Blow ups are compatible with base changes $h: Y \to X$, that is, $h_{(I)} = X_I \times X Y$. If $X = \text{Spec}(M)$ and $I = (f_1, \ldots, f_n)$ then
$X_I$ is glued from the charts $X_{f,a} = \text{Spec}(A[I - a])$ for $a \in I$, where $A[I - a]$ is the submonoid of $A^\gp$ generated by elements $b - a$ with $b \in I$.

**Lemma 2.2.19.** If $X$ is a monoscheme (resp. a fan) and $I \subseteq M_X$ (resp. $I \subseteq \overline{M}_X$) is a coherent ideal then the blow up $X_I \to X$ is a subdivision.

**Proof.** The claim is local on the base, so we can assume that $X = \text{Spec}(A)$ and $I = (f_1, \ldots, f_n)$. The birationality is clear. If $R$ is a valuative monoid and $\phi : A \to R$ is a homomorphism, then choosing $i$ so that $\phi(f_i)$ is minimal in $R$ we see that $\phi$ factors through $A[I - f_i]$. It follows that $\text{Spec}(R) \to X$ factors through $X_I$ via the $f_i$-chart, in particular, $X_I \to X$ is a subdivision. \hfill $\square$

2.2.20. Exactification. A homomorphism of monoids $P \to Q$ is exact if $P = Q \times Q^\gp$. A morphism of monoschemes (resp. fans) $f : Y \to X$ is exact if the morphisms $M_{X,f(y)} \to M_{Y,y}$ (resp. $\overline{M}_{X,f(y)} \to \overline{M}_{Y,y}$) are exact. In particular, an exact birational morphism is nothing else but a local isomorphism. It is easy to see that exact morphisms are preserved by base changes. The following result is a (very simple) analogue of the flattening theorem of Raynaud-Gruson.

**Theorem 2.2.21.** Assume that $X = \text{Spec}(P)$ is an affine monoscheme (resp. a fan) and $f : Y \to X$ is a morphism of finite type. Then there exists a finitely generated ideal $I \subseteq P$ such that the base change $f_I : Y_I \to X_I$ of $f$ with respect to the blowing up $X_I \to X$ is an exact morphism. In particular, if $f$ is birational, then $f_I$ is a local isomorphism.

**Proof.** Since the family of blow ups is filtered, we can fix a finite covering of $Y$ by affines $Y_i$ and prove the claim separately for each $Y_i$. So, we can assume that $Y$ is affine, and then $f$ is a base change of a morphism of fine monoschemes $Y_0 \to X_0$ by Lemma 2.1.9. This reduces us to the case when $X$ is fine, and the latter is proved in [Ogu18, Theorem II.1.8.1]. \hfill $\square$

Note that the same result holds when $X$ is quasi-compact, but we prefer not to work this out here.

2.3. Toric monoids over valuative monoids.

2.3.1. Notation. In the sequel, $R$ is a sharp valuative monoid of height one. For simplicity we assume that $R$ is divisible, and hence $R^\gp$ is a vector space over $\mathbb{Q}$. In addition, we fix an ordered embedding $R^\gp \to V_R := \mathbb{R}$ and denote its image by $V$, thus identifying $R$ and $V_{\geq 0}$. Note that $\emptyset$ and $m_R = R \setminus \{0\}$ are the only prime ideals of $R$, so $\text{Spec}(R)$ consists of a generic point $\eta = \text{Spec}(V)$ and a closed point $s$. For any $R$-monoscheme $f : X \to \text{Spec}(R)$ we set $X_s = f^{-1}(X_s)$ and $X_\eta = f^{-1}(\eta)$.

2.3.2. Faithful $R$-monoids. Let $M$ be an $R$-monoid with the structure homomorphism $\phi : R \to M$. In this case, one of the following possibilities holds:

1. The homomorphism $\phi$ is local: $\phi^{-1}(M^\times) = 0$. In this case we say that $M$ is faithful over $R$. This happens if and only if the closed fiber of $\text{Spec}(M) \to \text{Spec}(S)$ is non-empty.

2. The monoid $M$ is not faithful, and then $\phi^{-1}(M^\times) = R$. This can happen in two cases:

   (a) $\phi$ is not injective, in which case we say that $M$ is non-flat over $R$.

   (b) $\phi$ factors as $R \to V \to M$, in which case we say that $M$ is flat but not faithful over $R$.
2.3.3. *Faithful monoschemes.* We say that an $R$-monoscheme or an $R$-fan $X$ is *faithful* if any its point has a specialization in $X_x$. In other words, $X$ is glued from spectra of $R$-faithful monoids.

2.3.4. *$R$-toric monoids.* By an $R$-toric monoid we mean a flat saturated torsion-free $R$-monoid $P$ finitely generated over $R$. In particular, if $R = 0$ then $P$ is nothing else but a classical toric monoid. In the same venue, by an $R$-toric fan or a monoscheme we mean the one glued from finitely many spectra of $R$-toric monoids. Products in the categories of $R$-toric fans and monoschemes correspond to the saturated $R$-pushout. For example, the fiber product of $\text{Spec}(M)$ and $\text{Spec}(N)$ is $\text{Spec}((M \oplus_R N)^\text{sat})$.

2.3.5. *$V$-lattices.* By a $V$-lattice we mean a torsion-free abelian group $L$ which contains $V$ and is finitely generated over it. In particular, $L$ is an $R$-toric monoid. Note also that if $P$ is an $R$-toric monoid then $P_{\text{gp}}$ is a $V$-lattice. We define the $V$-rank $\text{rk}_V(L)$ of $L$ to be the $\mathbb{Z}$-rank of the lattice $L/V$.

**Lemma 2.3.6.** Let $L$ be a $V$-lattice and let $L_0$ be a subgroup of $L$.

(i) If $V \subseteq L_0$, then $L_0$ is a $V$-lattice, and $L/L_0$ is a lattice if and only if $L_0$ is saturated in $L$. In the latter case, $L$ splits non-canonically as $L_0 \oplus L/L_0$. In particular, $L \cong V \oplus \mathbb{Z}^n$, where $n = \text{rk}_V(L)$.

(ii) If $L_0 \cap V = 0$, then $L_0$ is a lattice, and $L/L_0$ is a $V$-lattice if and only if $L_0$ is saturated in $L$. In the latter case, $L$ splits non-canonically as $L_0 \oplus L/L_0$.

**Proof.** For (i), note that $L_0$ is a $V$-lattice and $L/L_0$ is a finitely generated. So, $L/L_0$ is a lattice if and only if it is torsion-free, which happens if and only if $L_0$ is saturated in $L$. The splitting is clear since $L/L_0$ is free.

For (ii), we note that everything except splitting is, again, very simple. To prove splitting, we should find a section of $L \rightarrow L/L_0$. Since $L/L_0 = V \oplus \mathbb{Z}^n$ by (i), it suffices to find sections of the composed maps $L \rightarrow L/L_0 \rightarrow V$ and $L \rightarrow L/L_0 \rightarrow \mathbb{Z}^n$. The first one is canonical, and the second one exists by the freeness of $\mathbb{Z}^n$. $\square$

**Corollary 2.3.7.** Any $R$-toric monoid $P$ non-canonically splits as $P = P^\times \oplus P^\text{gp}$. In addition,

(i) If $P$ is faithful, then $P^\times$ is a lattice disjoint from $V$ and $P^\text{gp}$ is an $R$-toric monoid.

(ii) If $P$ is not faithful, then $P^\times$ is a $V$-lattice and $P^\text{gp}$ is a toric monoid.

**Proof.** Only the splitting requires an argument. In particular, it is clear that $P^\times$ is either a lattice or a $V$-lattice. So, $P^\times$ splits off $P^\text{gp}$ by Lemma 2.3.6, and it remains to use Lemma 2.1.3. $\square$

In particular, the corollary reduces studying $R$-toric monoids to studying sharp ones. Furthermore, if $P$ is not faithful then $P^\text{gp}$ is toric, and the theory of such objects is classical. For this reason, the non-faithful case will be excluded in the sequel each time it requires a special consideration.

2.3.8. *Basic and smooth monoids.* Next, we will split toric monoids to further simpler blocks. We say that a monoid $P$ is *basic* if it does not contain prime elements.
Lemma 2.3.9. Any $R$-toric monoid $P$ splits as $P^b[t_1, \ldots, t_n]$, where $P^b$ is basic. Moreover, $(t_1), \ldots, (t_n)$ are precisely the principal prime ideals of $P$ and $P^b = P \setminus \cup_{i=1}^n (t_i)$. In particular, $P^b$ is uniquely determined and the elements $t_i$ are unique up to units.

Proof. Note that Spec$(P)$ is finite because $P$ is finitely generated over $R$, and hence $n$ is bounded. So, a decomposition exists by Lemma 2.1.5, and the uniqueness claim is easily checked.

Combining Lemma 2.3.9 with Corollary 2.3.7 we obtain a splitting $P = P^x \oplus \overline{T^x} = P^x \oplus \mathbb{N}^n \oplus \overline{T^b}$. The fact that $Q^x = (Q[t])^x$ for any monoid $Q$ implies that $(\overline{T^b})^x = \overline{T^b}$, so there is no ambiguity in the notation $\overline{T^b}$. We call $P^b$ and $\overline{T^b}$ the basic component of $P$ and the sharp basic component of $P$, respectively. If $P$ is faithful then $P^x = \mathbb{Z}^l$ and the above splitting can be written in the polynomial form as $P = \overline{T^b}[t_1, \ldots, t_n, \pm s_1, \ldots, \pm s_l]$.

An $R$-toric monoid $P$ will be called smooth if $\overline{T^b} = 0$. In particular, the splitting of $P$ can be recombined as $P^{sm} + \overline{T^b}$, where $P^{sm}$ is the largest smooth factor of $P$.

2.3.10. Polystable monoids. We have reduced study of $R$-toric monoids to study of their sharp basic component. A simplest example of a sharp basic monoid is $P_{n,\pi} = R[t_0, \ldots, t_n]/(\sum_{i=0}^n t_i = \pi)$, where $\pi \in m_R$ and $n \geq 0$. The monoids with $n > 0$ are non-smooth (and non-isomorphic), while $P_{0,\pi} = R$. An $R$-toric monoid $P$ is called simlicial if $\overline{T^b} = P_{n,\pi}$. An $R$-pushout of semistable monoids is called polystable. A faithful $R$-toric monoid $P$ is polystable if and only if $\overline{T}$ is the $R$-pushout of a free monoid and few $P_{n_i, \pi_i}$. Explicitly,

$$T = R[t_1, \ldots, t_n, t_{1,0}, \ldots, t_{1,n_1}, \ldots, t_{l,0}, \ldots, t_{l,n_l}]$$

$$/ \left( \sum_{j=0}^{n_1} t_{1,j} = \pi_1, \ldots, \sum_{j=0}^{n_l} t_{l,j} = \pi_l \right).$$

The following simple facts will not be used, so we omit a justification.

Remark 2.3.11. (i) The isomorphism class of a faithful polystable $P$ is determined by the rank of $P^x$, the rank $n$ of the free part, and the unordered tuple of pairs $((n_1, \pi_1), \ldots, (n_l, \pi_l))$ with $n_i > 0$.

(ii) Since $P_{n,\pi} \oplus_R V = V \oplus \mathbb{Z}^n$, a non-faithful $P$ is polystable if and only if it is smooth.

2.3.12. Simplical monoids. An embedding of saturated monoids $P \hookrightarrow Q$ is called a Kummer extension if $Q^{gp}/P^{gp}$ is finite and $Q$ is the saturation of $P$ in $Q^{gp}$. A sharp $R$-toric monoid $Q$ is called simplicial if it contains a semistable submonoid $P$ such that $Q/P$ is a Kummer extension.

2.3.13. Types of monoschemes. Let $P$ be one of the following properties: smooth, semistable, polystable, simplicial. We say that an $R$-toric monoscheme (resp. a fan) $X$ is $P$ at a point $x \in X$ if the monoid $M_{X,x}$ (resp. $\overline{M}_{X,x}$) is $P$, and $X$ is $P$ if it so at all its points. All these properties are not sensitive to units, hence $X$ is $P$ at $x$ if and only $\overline{X}$ is $P$ at $x$. 
3. Fans and polyhedral complexes

Throughout Section 3, $R$, $V$, and $V_\mathbb{R}$ are as in Section 2.3.1. We develop a basic theory of cones and fans associated with $R$-toric monoids, which is analogous to the usual theory of toric monoids, cones and fans. The latter will be referred to as the “classical case”.

3.1. $R$-toric monoids and special $V$-cones.

3.1.1. $V$-lattices in real vector spaces. By a $V$-lattice in a real vector space $W$ we mean a subgroup $L \subseteq W$ such that $L$ is a $V$-lattice, $V \subseteq L$ spans a line $V_\mathbb{R}$ in $W$ satisfying $V = L \cap V_\mathbb{R}$, and $L/V$ is a lattice in $W/V_\mathbb{R}$. This happens if and only if $W = \mathbb{R}^{1+n}$ and $L = V \oplus \mathbb{Z}^n$ for an appropriate basis of $W$. Note that once a $V$-lattice in $W$ is fixed, we obtain an embedding $R \hookrightarrow W$. For any $\pi \in \mathfrak{m}_R$ its image in $W$ will be denoted $v_\pi$.

Any abstract $V$-lattice $L$ determines a canonical real vector space $L_\mathbb{R}$ in which it embeds. For example, using a splitting $L = V \oplus \mathbb{Z}^n$ we can take $L_\mathbb{R} = V_\mathbb{R} \oplus \mathbb{R}^n$, and this is easily seen to be independent of the splitting. Alternatively, one can take $L_\mathbb{R} = (L \otimes \mathbb{R}) \oplus_{V \otimes \mathbb{R}} V_\mathbb{R}$, where $V \otimes \mathbb{R} \to V_\mathbb{R}$ is the map induced by the embedding $V \to V_\mathbb{R} = \mathbb{R}$.

3.1.2. Special $V$-cones. By a polyhedral cone with a $V$-integral structure we mean a real vector space $W_\sigma$ provided with a $V$-lattice $L_\sigma$ and a polyhedral cone $\sigma \subseteq L_\mathbb{R}$ with the vertex at $0$, a non-empty interior, and edges spanned by elements of $L_\sigma$. If, in addition, $v_\sigma \in \sigma$ then we say that $\sigma$ is a special $V$-cone. This property is independent of the choice of $\pi \in \mathfrak{m}_R$. A morphism of special $V$-cones $\sigma \to \tau$ is a linear map $f : W_\sigma \to W_\tau$ such that $f(v_\sigma) = v_\tau$, $f(L_\sigma) \subseteq L_\tau$, and $f(\sigma) \subseteq \tau$.

3.1.3. Cones and monoids. As in the classical case, to any $R$-toric monoid $M$ one can assign a special $V$-cone $\sigma = \sigma_M$ as follows: $L_\sigma = M^{\text{sp}}$, $W_\sigma = (L_\sigma)_\mathbb{R}$, and $\sigma = M_\mathbb{R}$ is the convex hull of $M$ in $W_\sigma$. It is spanned by the generators of $M$, and hence is a special $V$-cone. Clearly, the construction $M \mapsto \sigma_M$ is functorial.

Conversely, to any special $V$-cone $\sigma$ one can functorially associate the $R$-monoid $M_\sigma = M(\sigma) := \sigma \cap L_\sigma$. As in the classical case, these constructions are inverse:

**Theorem 3.1.4.** The functors $\sigma \mapsto M_\sigma$ and $M \mapsto \sigma_M$ are essentially inverse equivalences between the categories of $R$-toric monoids and special $V$-cones. In particular, for any special $V$-cone $\sigma$, the monoid $M_\sigma$ is $R$-toric.

**Proof.** First, let us prove the following claim for a special $V$-cone $\sigma$: (1) $M_\sigma$ is $R$-toric, (2) if $M \subseteq M_\sigma$ is a submonoid, which is saturated in $L_\sigma$ and contains $V \cap M_\sigma$ and non-zero elements on all edges of $\sigma$, then necessarily $M = M_\sigma$.

Choosing an appropriate basis we can assume that $L_\sigma = V \oplus \mathbb{Z}^n$ and $W_\sigma = V_\mathbb{R} \oplus \mathbb{R}^n$. Assume first that $\sigma$ contains $V_\mathbb{R}$. Then $\sigma$ splits as $V_\mathbb{R} \oplus \sigma'$, where $\sigma'$ is a rational polyhedral cone in $\mathbb{R}^n$. In addition, $V \subseteq M$ and hence $M$ splits as $V \oplus M'$, where $M'$ is saturated in $\mathbb{Z}^n$. By the classical results, $M_{\sigma'} = \sigma' \cap \mathbb{Z}^n$ is a toric monoid and $M' = M_{\sigma'}$. In particular, $M_\sigma = V \oplus M_{\sigma'}$ is $R$-toric and $M = M_\sigma$.

Assume now that $\sigma$ does not contain $V_\mathbb{R}$, and hence $\sigma \cap V_\mathbb{R} = \mathbb{R}_\mathbb{R}$. Note that $\sigma$ is the union of cones $\sigma_i$ spanned by $R_\mathbb{R}$ and a face $F_i$ of $\sigma$ which does not contain $R_\mathbb{R}$. Therefore, $M_\sigma = \cup_i M_{\sigma_i}$, and it suffices to prove that each monoid $M_{\sigma_i}$ is toric and coincides with $M_i := M \cap \sigma_i$. This reduces the question to the case of a single cone $\sigma_i$, and to simplify notation we replace $\sigma$ by $\sigma_i$, achieving that $R_\mathbb{R}$ is an
edge of $\sigma$ and all other edges are contained in a face $F$. Let $L'$ be the intersection of $V \oplus \mathbb{Z}^n$ with the hyperplane spanned by $F$. Clearly, $L'$ is a lattice of rank $n$ saturated in $V \oplus \mathbb{Z}^n$, and hence $V \oplus \mathbb{Z}^n = V \oplus L'$ by Lemma 2.3.6. So, changing coordinates we can assume that $L' = \mathbb{Z}^n$ and $F$ lies in $\mathbb{R}^n$. Then $\sigma = R_R \oplus \sigma'$, and hence $M_\sigma = R \oplus M_{\sigma'}$ for $M_{\sigma'} = \sigma' \cap L'$. By the classical results, $M_{\sigma'}$ is toric and coincides with $M \cap L'$. In particular, $M_\sigma = M$ is $R$-toric.

The rest is easy. If $\sigma$ is a special $V$-cone then $M_\sigma$ contains non-zero vectors on the edges of $\sigma$, and hence $\sigma_{M(\sigma)} = \sigma$. Conversely, if $M$ is an $R$-toric monoid then the inclusion $M \subseteq M(\sigma_M)$ is an equality by claim (2). \hfill \square

3.1.5. Sums of special $V$-cones. The usual direct sum $L_1 \oplus L_2$ of $V$-lattices is not a $V$-lattice because it contains $V^2$. Naturally, this problem should be remedied by switching to $V$-sums $L = L_1 \oplus_V L_2$, which is easily seen to be a $V$-lattice. (In fact, $L = (L_1 \oplus L_2) \oplus_V V$, so it is obtained from $L_1 \oplus L_2$ by replacing $V^2$ with $V$.) Similarly, instead of direct sums of special $V$-cones $\sigma$ and $\tau$ one should consider $\rho = \sigma \oplus_v \tau$ given as follows: $L_\rho = L_\sigma \oplus_V L_\tau$ and $\tau$ is the image of $\sigma \oplus \tau$ under the projection $W_\sigma \oplus W_\tau \to W_\rho$. One immediately checks that the equivalence $M \hookrightarrow \sigma_M$ respects sums: $\sigma(M \oplus_R N) = \sigma_N \oplus_V \sigma_N$.

3.1.6. Faithful cones. Similarly to faithful monoids (§2.3.2), we say that a special $V$-cone $\sigma$ is faithful if $\sigma \cap V = R$. Clearly the equivalences of Theorem 3.1.4 take faithful monoids to faithful cones. In fact, the case of non-faithful objects in this theorem is not so interesting because, as we saw in the proof of the theorem, the claim reduces to the classical case after factoring by $V$ and $V_R$.

3.1.7. Sharp cones. We say that a polyhedral cone $\tau$ is sharp if it does not contain lines (often one says that $\tau$ is strongly convex). If $\tau^\times$ denotes the maximal vector subspace of $\tau$, then $\tau := \tau/\tau^\times$ is sharp and $\tau$ non-canonically splits as $\tau^\times \oplus \tau$. Note that a splitting $M = M^\times \oplus \overline{M}$ of an $R$-toric monoid gives rise to such a splitting $M_R = M^\times_R \oplus \overline{M}_R$.

3.1.8. Simplicial cones. Let $\sigma$ be a $V$-special cone. We call $\sigma$ simplicial if the sharpening $\tau$ is a simplicial polyhedral cone.

**Lemma 3.1.9.** Let $\sigma$ be a faithful $V$-special cone. Then

(i) $n = \dim(W_{\sigma}) - 1 \geq 0$.

(ii) $\sigma$ is simplicial if and only if it is spanned by $\sigma^\times$ and $n + 1$ elements $t_0, \ldots, t_n$.

(iii) The elements $t_i$ in (ii) are linearly independent over $\sigma^\times$, and one can choose them so that $t_i$ are not divisible by integers $m > 1$ and $\sum_{i=0}^n a_i t_i = v_\pi$ for $\pi \in m_R$ and $a_i \in \mathbb{N}$ such that $(a_0, \ldots, a_n) = 1$. Furthermore, $a_i$ are unique up to permutation and $t_i$ are unique up to permutation and shifting by elements of $L_{\sigma^\times} = L_\sigma \cap \sigma^\times$.

**Proof.** By the faithfulness of $\sigma$, the image of $V_R$ in $W_{\sigma} = W_{\sigma}/\sigma^\times$ is non-zero, and hence (i) holds. Choose $\overline{t}_0, \ldots, \overline{t}_n \in L_{\sigma}$ that generate the edges of $\sigma$, then their lifts $t_i \in L_\sigma$ satisfy (ii) and are linearly independent over $\sigma^\times$. The image of $R_R$ lies in $\overline{\sigma}$, hence there exists $\pi \in m_R$ such that $\sum_{i=0}^n a_i \overline{t}_i = \overline{v}_\pi$ for some choice of $a_i \in \mathbb{N}$. Dividing the equation by the gcd of the coefficients, we can also achieve that $(a_0, \ldots, a_n) = 1$. Shifting $t_0$ by an element of $L_{\sigma^\times}$, we achieve that also $\sum_{i=0}^n a_i t_i = v_\pi$. The uniqueness is clear from the construction. \hfill \square
3.1.10. **Semistable cones.** A $V$-special cone $\sigma$ is **semistable** if it is faithful and simplicial, and an equality $\sum_{i=0}^{n} a_i t_i = v_\tau$ from Lemma 3.1.9(iii) satisfies the following two conditions: $a_i \in \{0, 1\}$ and $t_i$ generate $L_\sigma$ over $L_\sigma^\times$. In particular, renumbering $t_i$ we can achieve that $t_0 + \cdots + t_m = v_\tau$.

**Lemma 3.1.11.** A faithful $R$-toric monoid $M$ is simplicial (resp. semistable) if and only if the associated $V$-special cone $\sigma$ is simplicial (resp. semistable).

**Proof.** The case of semistable monoids and cones is obvious. To deal with the simplicial case note that if $M \subseteq N$ is a Kummer extension then $M_R = N_R$, and $\sigma_M$ and $\sigma_N$ are only distinguished by the $V$-lattices $M^{sp}$ and $N^{sp}$. This reduces the lemma to the following claim: a special $V$-cone $\sigma = (\sigma, L_\sigma, W_\sigma)$ is simplicial if and only if there exists a $V$-sublattice $L' \subseteq L_\sigma$ of finite index such that the special $V$-cone $\sigma' = (\sigma, L', W'_\sigma)$ is semistable. To prove the latter it suffices to choose $t_i$ as in Lemma 3.1.9(iii) and take $L'$ to be the $V$-lattice generated over $V \oplus L_\sigma^\times$ by $t'_i$, where $t'_i = t_i$ if $a_i = 0$ and $t'_i = a_i t_i$ otherwise. $\square$

3.2. **$R$-monoschemes and special $V^\perp$-cones.** Our next goal is to study geometry of cones in dual spaces.

3.2.1. **Special $V^\perp$-cones.** By a special $V^\perp$-cone $\tau$ we mean a vector space $W_\tau$, a $V$-lattice $L_\tau$ in the dual space $W_\tau^*$, and a sharp cone $\tau$ in $W_\tau$, which is defined by finitely many inequalities $l_i(x) \geq 0$ with $l_i \in L_\tau$. A morphism of special $V^\perp$-cones $\tau \rightarrow \rho$ is a linear map $f : W_\tau \rightarrow W_\rho$ such that $f(\tau) \subseteq \rho$ and the dual map $f^*$ takes $L_\rho$ to $L_\tau$.

For any special $V$-cone $\sigma$ we define its dual $\sigma^*$ as follows: $W_{\sigma^*} = W_{\sigma}^*$, $L_{\sigma} = L_{\sigma^*}$, and $\sigma^*$ is given in $W_{\sigma}^*$ by the inequalities $l_i(x) \geq 0$ with $l_i \in M_{\sigma}$. It suffices to take a set $\{l_i\}$ of generators of $M_{\sigma}$, hence $\sigma^*$ is a special $V^\perp$-cone. In the same way, one defines duals of special $V^\perp$-cones, which are special $V$-cones. The usual duality between cones with non-empty interior and sharp cones in $R^n$ implies the following result:

**Lemma 3.2.2.** The duality functors establish essentially inverse equivalences between the category of special $V^\perp$-cones and the category opposite to the category of special $V$-cones.

**Remark 3.2.3.** In the classical toric case, dual cones are also rational, so their geometry is similar. For $V$-cones this is not the case. For example, special $V$-cones possess subdivisions by simplicial special $V$-cones, as follows easily from the argument in the proof of Theorem 3.1.4, but special $V^\perp$-cones may not have such a subdivision. In fact, the main result we will prove about them later states that they possess subdivisions by polystable special $V^\perp$-cones.

3.2.4. **Products.** Products sums is another feature that distinguishes $V$-cones and $V^\perp$-cones. As in the case of $V$-cones (see §3.1.5), the direct product of $V^\perp$-cones $\sigma \times \tau$ is not a $V^\perp$-cone. The natural replacement this time is the $V$-product $\rho = \sigma \times_V \tau$ defined as follows: $L_\rho = L_\sigma \oplus_V L_\tau$, in particular, $W_\rho$ is the hyperplane in $W_\sigma \times W_\tau$ given by equalizing the functional induced from $v_\rho$ on $W_\sigma$ and $v_\tau$ on $W_\tau$, and $\rho = (\sigma \times \tau) \cap W_\rho$. Clearly, this operation is dual to $V$-sums: if $\sigma$ and $\tau$ are $V$-special cones then $\sigma^* \times_V \tau^* = (\sigma \oplus_V \tau)^*$.
3.2.5. **Faithfulness.** We say that a special $V^\perp$-cone $\tau$ is *faithful* if $\tau^*$ is so. Note that $\tau$ lies in the halfspace given by $v_\tau(x) \geq 0$, and $\tau$ is faithful if and only if it is not contained in the hyperplane $W_0$ given by $v_\tau(x) = 0$. The theory of non-faithful special $V^\perp$-cones thus reduces to the theory of rational cones in $W_0$.

3.2.6. **Cones and affine monoschemes.** Combining Theorem 3.1.4 and Lemma 3.2.2 we obtain that the category of special $V^\perp$-cones is equivalent to the category dual to the category of $R$-toric monoids. Therefore, we obtain a natural equivalence between the categories of affine $R$-toric monoschemes and special $V^\perp$-cones, which associates to $X = \text{Spec}(M)$ the special $V^\perp$-cone $\tau = \tau_X$ with $W_\tau = (M^\gp)^*$, $L_\tau = M^\gp$, and $\tau = \sigma^*_M$. Note that localizations $\text{Spec}(M_p) \hookrightarrow X$ correspond to embeddings $\tau_p \hookrightarrow \tau$, where $\tau_p$ is the face in $\tau$ cut off by the conditions $f = 0$ for $f \notin p$. In particular, it is easy to see that this establishes a one-to-one correspondence between the faces of $\tau$ and points of $X$, and the points of $X_\eta$ correspond to the faces contained in $W_0$.

3.2.7. **Embedded cone complexes and $R$-monoschemes.** The functor $X \mapsto \tau_X$ takes localizations to face embeddings and hence can be globalized, once we define global cone complexes. Loosely speaking, such a complex is obtained by gluing finitely many special $V^\perp$-cones along face embeddings. However, the procedure is a little subtle, in particular, cones may intersect at few faces.

By a *locally embedded $V^\perp$-cone complex* $\tau$ we mean the following datum: a real vector space $W_\tau$, a $V$-lattice $L_\tau$ in $W_\tau^*$, and a topological space $\tau$ with a finite *face set* $\{\tau_i\}$ of closed subspaces provided with a structure $(W_\tau, L_\tau, \tau_i)$ of special $V^\perp$-cones so that the following conditions are satisfied: (1) each inclusion $\tau_i \hookrightarrow \tau_j$ of faces agrees with a face embedding of cones in $W_\tau$, (2) all faces of each $\tau_i$ are in the face set, (3) each intersection $\tau_i \cap \tau_j$ is a union of faces of both $\tau_i$ and $\tau_j$. Morphisms of such complexes are defined in the natural way and using Lemma 3.2.2 and a gluing argument one immediately obtains the following result.

**Theorem 3.2.8.** The functor $X \mapsto \tau_X$ uniquely extends to an equivalence between the categories of $R$-toric monoschemes and locally embedded $V^\perp$-cone complexes, that will also be denoted $X \mapsto \tau_X$. The maps of cones to affine monoschemes glue to global maps $\tau_X \to X$ such that face interiors of $\tau_X$ are precisely preimages of points of $X$.

**Remark 3.2.9.** (i) By definition, the embeddings $\tau_i \hookrightarrow W_\tau$ agree and give rise to a continuous map $\tau \to W_\tau$, whose image is a $V^\perp$-cone complex $\overline{\tau}$ in $W_\tau$. We will call $\overline{\tau}$ *embedded $V^\perp$-cone complex*. In a sense, $\tau$ is obtained from $\overline{\tau}$ by multiplying few its cones. Similarly to the theory of schemes, one can naturally define the notion of separated monoschemes, and it is easy to check that $\tau_X$ is embedded if and only if $X$ is separated.

(ii) Products of $R$-toric monoschemes correspond to $V$-products of complexes. Indeed, this reduces to the affine case, and then products correspond to $R$-pushouts of monoids, which are taken by the functor $M \mapsto \sigma_M$ to $V$-sums of special $V$-cones.

3.2.10. **Non-embedded cone complexes and $R$-fans.** Next, we would like to prove an analog of Theorem 3.2.8 for $R$-toric fans. In the affine setting this means that we restrict to the subcategory of sharp $R$-toric monoids. Clearly, the corresponding subcategories of cones are the category of sharp special $V$-cones, and the category
of special $V^\bot$-cones with non-empty interior, that is, special $V^\bot$-cones such that $\tau$ spans $W_\tau$. Objects of the latter category will be denoted $\mathcal{F} = (W_\tau, L_\tau, \tau)$. The main difference with the category of arbitrary special $V^\bot$-cones is that for a face embeddings $\rho \leftrightarrow \tau$, the map $W_\rho \leftrightarrow W_\tau$ is injective and the map $L_\tau \rightarrow L_\rho$ is surjective, rather than isomorphisms. In addition, a new feature is that a morphism $(W_\tau, L_\tau, \tau) \rightarrow (W_\rho, L_\rho, \rho)$ is determined already by the set-theoretical map $\tau \rightarrow \rho$.

A (non-embedded) $V^\bot$-cone complex is a topological space $\mathcal{F}$ with a finite face set $\{\tau_i\}$ of closed subspaces provided with a structure $(W_i, L_i, \tau_i)$ of special $V^\bot$-cones with non-empty interior so that the following conditions are satisfied: (1) each inclusion $\tau_i \leftrightarrow \tau_j$ of faces underlies a face embedding of special $V^\bot$-cones, (2) all faces of each $\tau_i$ are in the face set, (3) each intersection $\tau_i \cap \tau_j$ is a union of faces of both $\tau_i$ and $\tau_j$. If each $\tau_i \cap \tau_j$ is a single face (maybe empty) then we say that the complex is strict.

**Remark 3.2.11.** One often works only with strict complexes because this is technically easier. On the algebra-geometric side this corresponds to working with toroidal structures without self-intersections (as in [KKMS73]). On the other hand, arbitrary complexes can be easily subdivided to strict ones. For example, in the classical case this can be achieved by the barycentric subdivision.

3.2.12. **Equivalence with fans.** Given an affine $R$-toric fan $\overline{X} = \text{Spec}(M)$ consider the special $V^\bot$-cone $\overline{\tau}_X = \overline{\tau}_{\text{Spec}(M)}$. Clearly, $\overline{M}_R$ is sharp and hence $\overline{\tau}_X$ has a non-empty interior. So, $\overline{X} \mapsto \overline{\tau}_X$ is a functor to the category of special $V^\bot$-cones with non-empty interior. It is easy to see that it takes localizations to face embeddings and hence globalizes, yielding the following analog of Theorem 3.2.8.

**Theorem 3.2.13.** The functor $\overline{X} \mapsto \overline{\tau}_X$ uniquely extends to an equivalence between the categories of $R$-toric fans and non-embedded $V^\bot$-cone complexes, that will also be denoted $\overline{X} \mapsto \overline{\tau}_X$.

3.3. **$V$-polyhedral complexes.** In the case of faithful fans or monoschemes, one can replace special $V^\bot$-cones by polyhedral sections. In this section we will work this out in detail.

3.3.1. **The canonical polyhedral section.** A faithful special $V^\bot$-cone $\tau$ is determined by the canonical section $\tau_1 = \tau \cap W_1$, where $W_1$ is the affine hyperplane given by $v_\pi(x) = \pi$. Clearly, $\tau_1$ is a sharp polyhedron (i.e. a polyhedron not containing lines), satisfying a natural $V$-integrality condition that we are going to formalize below.

3.3.2. **$V$-affine spaces.** By a $(Z, V)$-affine or simply $V$-affine real vector space we mean an $n$-dimensional affine real vector space $U$ (i.e. a torus of $R^n$) provided with a subgroup $A_U$ of the group of affine functions $U \rightarrow R$ such that the elements of $V$ are precisely the constant functions in $A_U$, the group $A_U/V = Z^n$ is a lattice of rank $n$ (in particular, $A_U$ is a $V$-lattice), and the functions of $A_U$ distinguish any pair of points of $U$. A $V$-affine map $f: U \rightarrow W$ between $V$-affine real spaces is an affine map $f$ such that $f^*(A_W) \subseteq A_U$. In particular, the elements of $A_U$ are precisely the $V$-affine functions $U \rightarrow R$.

**Remark 3.3.3.** (i) After an appropriate choice of coordinates $t = (t_1, \ldots, t_n)$, we have $U = R^n$ and $A_U = V \oplus Z^n$ with $Z$ spanned by the dual basis. The $V$-affine functions are then of the form $f = v + \sum_{i=1}^n a_i t_i$ with $a_i \in Z$ and
v ∈ V. The freedom to choose coordinates is limited to a transformation $t' = At + v$, where $A ∈ GL_n(\mathbb{Z})$ and $v ∈ V^n$. A similar theory of $(S, V)$-affine spaces can be developed for any subring $S ⊆ R$ and $S$-submodule $V ⊆ R$. See also Remark 3.3.5 below.

(ii) For any point $u ∈ U$ the set of functions $f ∈ A_U$ such that $f(u) = 0$ is a lattice of rank bounded by $n$. We say that $u$ is $V$-rational if the rank is precisely $n$.

It is easy to see the set of $V$-rational points is a torsor for the subgroup $V^n$ of $R^n$. For example, use that rational points correspond to splittings $\mathbb{Z}^n → A_U$ of the sequence $V → A_U → \mathbb{Z}^n$.

3.3.4. Special polyhedra. By a special $V$-polyhedron $P$ we mean a $V$-affine real space $U = U_P$ and a sharp polyhedron $P ⊆ U$ defined by finitely many inequalities $f_j ≥ 0$, with $f_j ∈ A_U$. A morphism of special $V$-polyhedrons $P → Q$ is any $V$-affine map $U_P → U_Q$ that takes $P$ to $Q$. If $P$ is bounded then we call it a $V$-affine polytope.

Remark 3.3.5. (i) Let $S ⊆ R$ be a subring, $L ⊆ R$ an $S$-module, $F = \text{Frac}(S)$ the fraction field and $V = L ⊗_S F$. Berkovich introduced in [Ber04, Section 1] $(S, L)$-polytopes in $R^n$ (the notation in [Ber04] are multiplicative). On the set-theoretical level, it is a polytope in $R^n$ whose vertexes lie in $V^n$ and edge slopes lie in $F$. In particular, $(S, L)$-polytopes and $(F, V)$-polytopes are not distinguished set-theoretically, but they do have different groups of affine functions.

(ii) If $V$ is a vector space over $Q$ then a $(\mathbb{Z}, V)$-polytope is a $V$-polytope in our sense, where one takes $A_U = V ⊕ \mathbb{Z}^n$. For comparison, groups of affine functions on $(Q, V)$-polytopes are of the form $V ⊕ Q^n$.

3.3.6. Products. Products in the category of special polyhedra correspond to usual products. Namely, $R = P × Q$ is defined as the usual set-theoretical product (or Minkowski sum of polyhedra) and, in addition, $U_R = U_P × U_Q$ and $A_R = A_P ⊕ A_Q$. This agrees with the $V$-product of $V \perp$-cones: $(σ ×_V τ)_1 = σ_1 × τ_1$.

3.3.7. Embedded polyhedral complexes. By a locally embedded $V$-polyhedral complex we mean a $V$-affine real space $U = U_P$ and a topological space $P$ covered by closed subspaces $P_i$ called faces, which are provided with the structure of special $V$-polyhedra in $U$ and satisfy the following conditions: (1) each inclusion $P_i → P_j$ of faces underlies a face embedding of special $V$-polyhedra, (2) all faces of each $P_i$ are in the face set, (3) each intersection $P_i ∩ P_j$ is a union of faces of both $P_i$ and $P_j$. As in the cone case, $P$ covers a $V$-polyhedral complex in $U_P$ and is obtained from the latter by multiplying some faces.

A morphism $P → Q$ consists of a continuous map $P → Q$ and a $V$-affine map $U_P → U_Q$ compatible with the projections $P → U_P$ and $Q → U_Q$. Clearly the canonical section functor $τ ↦ τ_1$ on special $V \perp$-cones is compatible with face maps hence globalize to an equivalence between the categories of faithful embedded $V \perp$-cone complexes and embedded $V$-polyhedral complexes. Combining this with Theorem 3.2.8 we obtain

Theorem 3.3.8. The functors $X ↦ τ_X$ and $τ ↦ τ_1$ induce equivalences of the following three categories: (1) faithful $R$-toric monoschemes, (2) faithful embedded $V \perp$-cone complexes, (3) embedded $V$-polyhedral complexes.

Remark 3.3.9. (i) One can also easily describe inverse equivalences. In particular, $τ$ is reconstructed from $P = τ_1$ as the cone over $P$ with $L_τ = A_P$, and
if $P$ is a polyhedron then $X = \text{Spec}(M)$ is reconstructed by setting $M$ to be the monoid of all non-negative $V$-affine functions on $P$.

(ii) The correspondences respect products: products of monoschemes over $R$ correspond to $V$-products of $V^\bot$-cone complexes and products of $V$-polyhedral complexes. All languages are equivalent, but it is often more natural to work within the framework of polyhedral complexes because then products become the most natural ones.

3.3.10. Non-embedded polyhedral complexes. Similarly to cone complexes, one can also define a non-embedded version as follows. First, one restricts to the subcategory of special $V$-polyhedra with non-empty interior and modifies the notion of face embedding accordingly. Then one copies the definition of cone complexes: a (non-embedded) $V$-polyhedral complex is a topological space $P$ with a finite face set $\{P_1\}$ of subspaces provided with a structure $(W_i, L_i, P_1)$ of special $V$-polyhedra so that conditions (1)–(3) as in §3.3.7 are satisfied.

As in the embedded case, the functor $\mathfrak{P} \mapsto \mathfrak{P}_1$ preserves face embeddings, and using Theorem 3.2.13 we obtain

**Theorem 3.3.11.** The functors $\mathfrak{X} \mapsto \mathfrak{X}_P$ and $\mathfrak{P} \mapsto \mathfrak{P}_1$ induce equivalences of the following three categories: (1) faithful $R$-toric monoschemes (resp. fans) and let $\phi$ and $\phi_1$ be the corresponding morphisms between (resp. non-embedded) cone and polyhedral complexes. Then the morphisms $f$, $\phi$ and $\phi_1$ are subdivisions or partial subdivisions if and only if at least one of them is a subdivision or a partial subdivision, respectively.

**Proof.** The two cases are similar, so we will work with fans for concreteness. The equivalence is obvious for $\phi$ and $\phi_1$, hence it suffices to compare a morphism of fans $f: Y \to X$ and the induced morphism $\phi: \tau \to \rho$ of cone complexes. Furthermore, the property of being a (partial) subdivision is local on the target, hence we can assume that $X = \text{Spec}(M)$. Also, we claim that $f$ is birational if and only if $\phi$ is an embedding locally on $\tau$. Indeed, this is a local claim, hence we can assume that $Y = \text{Spec}(N)$ is also affine. Then $Y \to X$ is birational if and only if $M^{\text{gp}} \to N^{\text{gp}}$. By duality, this happens if and only if $W_\tau \hookrightarrow W_\rho$, that is $\phi$ is an embedding of polyhedra. So, we can assume in the sequel that $f$ is birational.

Assume first that $Y = X_f$ is the blow up of $X$ along an ideal $I = (f_1, \ldots, f_n)$. Then a direct inspection shows that $\phi$ is a subdivision. Indeed, $\tau$ is covered by the polytopes $\tau_i$ corresponding to the charts $\text{Spec}(M[I - f_i])$. So, $\tau_i$ is cut off from $\rho$ by the inequalities $f_i \geq f_1, \ldots, f_n \geq f_i$, and hence $\tau$ is a subdivision of $\rho$.

Returning to the general case, assume that $X' = X_f$ is a blow up, $Y' = Y_f$ its pullback to $Y$, and $\phi': \tau' \to \rho'$ the induced morphism of cone complexes. Since $X' \to X$ and $Y' \to Y$ are subdivisions by Lemma 2.2.19, $f$ is a (partial) subdivision if and only if $f': Y' \to X'$ is so. Since $\tau' \to \tau$ and $\rho' \to \rho$ are subdivisions, $\phi$ is a (partial) subdivision if and only if $\phi'$ is so. Therefore, it suffices to prove the theorem for $f'$ instead of $f$, and by use of Theorem 2.2.21 we can assume that $f$...
Remark 3.4.3. In fact, the faithfulness assumption is only needed to compare $f$ and $\phi$ to $\phi_1$. Our comparison of $f$ and $\phi$ applies in the non-faithful case too.

3.4.4. Polystable complexes. Let $\tau$ be a faithful special $V^\perp$-cone and $P = \tau_1$ the corresponding special $V$-polyhedron $P$. We say that $P$ and $\tau$ are semistable (resp. simplicial) if the dual $V$-special cone $\tau^*$ is so. We say that $P$ (resp. $\tau$) is polystable if it is a product (resp. a $V$-product) of semistable ones.

Remark 3.4.5. (i) Clearly, $\tau$ is simplicial if and only if the underlying cone is simplicial. Note that $\tau$ may have edges (or even a facet) parallel to the $V$-affine space of $P$, and in this case $P$ is an "unbounded simplex".

(ii) Unravelling the definitions one can describe the semistability condition for $\tau$ and $P$ explicitly. For example, $P$ is semistable if and only if there exist $V$-affine functions $t_0, \ldots, t_n, s_1, \ldots, s_l \in U_P$ such that $t_0 + \cdots + t_m = \pi$ for some $m \leq n$ and $\pi \in m_R$, the polyhedron $P$ is given by the conditions $t_i \geq 0$ and $s_j = 0$ for $0 \leq i \leq n$ and $0 \leq j \leq l$, and $A_U = V \oplus \mathbb{Z}^{n+l}$ with the second factor spanned by $t_1, \ldots, t_n, s_1, \ldots, s_l$.

A $V^\perp$-cone complex (resp. a $V$-polyhedral complex) is called simplicial, semistable or polystable if all its cones (resp. polyhedra) are so. This applies both to the locally embedded and non-embedded versions.

Lemma 3.4.6. Let $X$ be an $R$-toric monoscheme or fan, let $\tau$ be the associated special $V^\perp$-complex, and let $P$ be the associated $V$-affine polyhedral complex. Then $X$ is simplicial, semistable or polystable if and only if $\tau$ is so.

Proof. For concreteness we consider the case of monoschemes. The claim is local, hence we can assume that $X = \mathrm{Spec}(M)$. By Lemma 3.1.11, $M$ satisfies any of these properties if and only if $\sigma_M$ does, and by definition the latter happens if and only if $\tau = (\sigma_M)^*$ and $P = \tau_1$ satisfy the same property.

3.4.7. Rational polyhedrons. Our construction of polystable subdivisions will be done by first achieving a weaker property that we are going to define now. Note that any special $V$-polyhedron $P$ can also be viewed as a $(Q,V)$-polyhedron or a rational $V$-polyhedron, that we denote $P_Q$. The functor $P \mapsto P_Q$ is faithful and essentially surjective but far from begin full. This happens because there are many rational but non-integral affine maps, for example, $A_P \otimes Q = A_P \otimes Q$, so one usually has that $\mathrm{Mor}(P,R) \subseteq \mathrm{Mor}(P_Q,R)$.

3.4.8. Rational splittings. The functor $P \mapsto P_Q$ preserves products, but it may freely happen that a non-invertible morphism $Q \times R \rightarrow P$ induces an isomorphism $Q_P \times R_P \rightarrow P_Q$. Thus, if $P$ splits rationally into a product, there might be obstacles to lift it to a splitting of $P$ itself. In fact, if $P_Q = \prod_{i=1}^n Q_i$ for rational $V$-polyhedra, then $A_P \otimes Q = A_{Q_1} \oplus_V \cdots \oplus_V A_{Q_n}$ and projections of the $V$-lattice $A_P$ onto the summands give rise to $V$-lattices $A_i$ that refine $Q_i$ to $V$-polyhedra $P_i = (Q_i, A_i)$. The induced map $A_1 \oplus_V \cdots \oplus_V A_n \rightarrow A_P$ is an injective map between $V$-lattices of the same rank, hence it is of finite index $r$ which we call the index of the rational splitting. Note that $r$ measures how far the rational splitting is from being liftable to an integral one, in particular, $r = 1$ if and only if the map $P \rightarrow \prod_{i=1}^n P_i$ is an
Proposition 4.1.2. All of whose cells are polystable as $(\mathbb{Z}, V)$-polytopes.

Example 3.4.9. Let $q, r \in \mathbb{R}$ be linearly independent over $\mathbb{Q}$ and $V = q \mathbb{Z} \oplus r \mathbb{Z}$. In the standard $V$-affine plane consider the $V$-polytope $P$ with vertices $(0, 0)$, $(q, q)$, $(r, -r)$, $(q + r, q - r)$, and let $Q$ and $R$ be the intervals between the origin and the points $(q, q)$ and $(r, -r)$, respectively. Clearly, $P = Q \times R$ rationally, but the index is two because $(1, 1)$ and $(1, -1)$ generate a sublattice of index 2 in $\mathbb{Z}^2$.

Remark 3.4.10. An analog of the above phenomenon exists in the theory of abelian varieties. It usually happens that an abelian variety $A$ can be split into a product of abelian varieties only after replacing it with an isogeneous one. The rank in our case is an analog of the degree of a minimal isogeny needed for splitting.

3.4.11. Polysimplicial polyhedrons. We say that a special $V$-polyhedron $P$ is polysimplicial if $P = \prod_{i=1}^{n} P_i$, where $P_i$ are simplicial $V$-polyhedrons. If such a decomposition exists only on the level of rational $V$-polyhedra and $r$ is its index, then we say that $P$ is rationally polysimplicial of index $r$.

4. Polystable subdivisions of $(\mathbb{Z}, V)$-polytopes and $(\mathbb{Z}, V)$-polyhedral complexes

4.1. Polytopes and Minkowski sums. A polytope is the convex hull of a finite set of points in $\mathbb{R}^n$. Alternatively, it is a bounded set of the form $\{x \in \mathbb{R}^n : Ax \leq b\}$ where $A \in \mathbb{R}^{m \times n}$ and $b \in \mathbb{R}^m$. The dimension of a polytope is the dimension of the smallest affine subspace containing the polytope. A simplex is the convex hull of a set of affinely independent points. The Minkowski sum of sets $A_1, \ldots, A_r \subset \mathbb{R}^n$ is the set

$$A_1 + \cdots + A_r := \{x_1 + \cdots + x_r : x_i \in A_i \text{ for all } i\}.$$  

A product of simplices is a polytope of the form $P = A_1 + \cdots + A_r$ where each $A_i$ is a simplex and $\dim(A_1) + \cdots + \dim(A_r) = \dim(P)$.

A face of a polytope $P \subset \mathbb{R}^n$ is a set $F \subset P$ such that there exists a linear functional $\phi : \mathbb{R}^n \to \mathbb{R}$ and $c \in \mathbb{R}$ such that $\phi(x) = c$ when $x \in F$ and $\phi(x) < c$ when $x \in P \setminus F$. When this is true, we say that such a pair $(\phi, c)$ supports $F$. By this definition, the empty set and $P$ are both faces of $P$. A vertex is a face of dimension 0, an edge is a face of dimension 1, and a facet is a face of dimension $\dim(P) - 1$. The graph of $P$ is the 1-skeleton of $P$. We use $S(P)$, $E(P)$, and $G(P)$ to denote the vertex set, edge set, and graph of $P$, respectively.

A polyhedral complex is a finite collection of $k$-dimensional polytopes in $\mathbb{R}^n$, called cells, such that the intersection of any two cells is a face of both. Given a polyhedral complex $X$, we let $S(X)$ and $E(X)$ denote the union of the vertex sets and edge sets, respectively, over all cells of $X$. A subdivision of a polytope $P$ is a polyhedral complex whose union of cells equals $P$.

4.1.1. Polystable subdivisions of $(\mathbb{Z}, V)$-polytopes. Let us first note that $(\mathbb{Z}, V)$ are closed under Minkowski sum.

Proposition 4.1.2. If $P_1, \ldots, P_r$ are $(\mathbb{Z}, V)$-polytopes, then $P_1 + \cdots + P_r$ is a $(\mathbb{Z}, V)$-polytope.

Recall that a polystable subdivision (or polystable refinement) is a $(\mathbb{Z}, V)$-subdivision all of whose cells are polystable as $(\mathbb{Z}, V)$-polytopes. Our goal is to prove the following.
Theorem 4.1.3. Every \((\mathbb{Z}, V)\)-polytope has a polystable subdivision.

4.1.4. A counterexample for semistability. Before we continue with the proof of Theorem 4.1.3, let us quickly discuss why we cannot hope to obtain a triangulation (into simplices) of rational facet slopes in general. We have the following lemma

Lemma 4.1.5. Consider a \(d\)-simplex in \(\mathbb{R}^d\) with rational facet slopes. If \(d\) vertices of the simplex are rational, then all vertices of the simplex are rational.

We conclude:

Proposition 4.1.6. A \(d\)-polytope \(P\) has a triangulation by simplices with rational facet slopes if and only if it is a dilation of a rational polytope.

Proof. If \(P\) is a dilation of a rational polytope, providing a rational triangulation is an easy exercise. If, on the other hand, \(Q\) is a subdivision of \(P\) into simplices of rational facet slopes, dilate and translate it and \(P\) so that one of the edges has only rational vertices. Then all the remaining vertices of incident simplices are rational as well. Since any two simplices of \(Q\) are connected by a path of simplices such that subsequent elements intersect in a simplex of dimension \(d - 1\). But then all vertices in this dilation are rational. Hence \(P\) is the dilation of a rational polytope itself. \(\square\)

It follows that, for instance, every rectangle with irrational ratio of side lengths cannot be triangulated with triangles of rational slope.

4.2. Mixed subdivisions.

4.2.1. Mixed subdivisions. We now follow [LRS10, Section 9]. Let \(P_1, \ldots, P_r \subset \mathbb{R}^n\) be polytopes and \(P = P_1 + \cdots + P_r\). A mixed subdivision of \(P\) with respect to \(P_1, \ldots, P_r\) is a subdivision of \(P\) where each cell \(C\) is given a label \((C_1, \ldots, C_r)\) such that the following hold:

(i) For each \(i\), \(C_i\) is a polytope with \(S(C_i) \subseteq S(P_i)\).

(ii) \(C = C_1 + \cdots + C_r\).

(iii) If \(C, C'\) are two cells labeled \((C_1, \ldots, C_r)\) and \((C'_1, \ldots, C'_r)\), then for each \(i\), \(C_i \cap C'_i\) is a face of both \(C_i\) and \(C'_i\).

A mixed subdivision is fine if for every cell \(C\) with label \((C_1, \ldots, C_r)\), each \(C_i\) is a simplex and \(\dim(C_1) + \cdots + \dim(C_r) = \dim C\).

Example 4.2.2. Assume that \(P_1\) and \(P_2\) are \(n\)-dimensional simplices in \(\mathbb{R}^n\) with vertices \(A_0, \ldots, A_n\) and \(B_0, \ldots, B_n\). Then the simplices \(Q_i, 0 \leq i \leq n + 1\) with vertices \(A_0, \ldots, A_i, B_{i+1}, \ldots, B_n\) form a fine mixed subdivision of \(P = P_1 + P_2\).

Mixed subdivisions arise naturally from subdivisions of Cayley polytopes.

4.2.3. Cayley polytopes. The geometric construction of the previous section is easily generalized to higher dimensions. For a family \(P_{[r]} = (P_1, \ldots, P_r)\) of \(r\) polytopes in \(\mathbb{R}^d\), we define the Cayley polytope as

\[ C(P_{[r]}) := \text{conv} \left( \bigcup_{i=1}^r P_i \times e_i \right) \subseteq \mathbb{R}^d \times \mathbb{R}^r. \]

The coordinate projection \(\mathbb{R}^d \times \mathbb{R}^r \to \mathbb{R}^r\) restricts to a linear projection

\[ \pi : C(P_{[r]}) \longrightarrow \Delta_r = \text{conv}\{e_1, \ldots, e_r\} \] (1)
of the Cayley polytope to the (geometric) standard \((r - 1)\)-simplex \(\Delta_r\). It is easy to see that for \(\lambda = (\lambda_1, \ldots, \lambda_r) \in \Delta_r\), we have
\[
\pi^{-1}(\lambda) \cong \lambda_1 P_1 + \cdots + \lambda_r P_r.
\] (2)

Triangulations of Cayley polytopes restrict therefore to mixed subdivisions of slices.

The proposition suggests that the boundary of the Cayley polytope \(\mathcal{C}(P_{[r]})\) is stratified along the facial structure of the cardinality \(r\) simplex \(\Delta_r\). We define the Cayley complex \(T_{[r]} = T(P_{[r]})\) as the closure of \(\pi^{-1}(\text{relint} \Delta_r) \cap \partial \mathcal{C}(P_{[r]})\).

4.2.4. Regular subdivisions. Let \(P \subset \mathbb{R}^n\) be a polytope and let \(S \subset \mathbb{R}^n\) be a finite set such that \(\text{conv}(S) = P\), where “conv” denotes convex hull. Let \(f : S \to \mathbb{R}\) be any function. The lift of \(P\) with respect to \(f\) is the polytope
\[
P^f := \text{conv}\{(s, f(s)) \in \mathbb{R}^{n+1} : s \in S\}.
\]
A face \(F\) of a polytope is a lower facet if it is supported by \((\phi, c)\) where \(\phi(0, \ldots, 0, 1) < 0\). Let \(\pi : \mathbb{R}^{n+1} \to \mathbb{R}\) be the projection map onto the first \(n\) coordinates. Then for any lift \(P^f\), the set
\[
\{\pi(F) : F\text{ is a lower facet of } P^f\}
\]
is the set of cells of a subdivision of \(P\). We say that this subdivision is induced by \(f\). A subdivision is regular if it is induced by some \(f\).

Let \(P_1, \ldots, P_r \subset \mathbb{R}^n\) be polytopes and let \(P = P_1 + \cdots + P_r\). For each \(i\), let \(f_i : S(P_i) \to \mathbb{R}\) be any functions. Then the set
\[
\{\pi(F) : F\text{ is a lower facet of } P_i^{f_i} + \cdots + P_r^{f_r}\}
\]
is a regular mixed subdivision of \(P\). We say that this mixed subdivision is induced by \(f_1, \ldots, f_r\). If the \(f_i\) are generic, then the induced mixed subdivision is fine. In particular, this implies that there exists a fine mixed subdivision of \(P\) with respect to \(P_1, \ldots, P_r\).

4.3. Proof of Theorem 4.1.3, preparation:

4.3.1. Construction of polytopes from edges. We first prove the following weaker Lemma

Lemma 4.3.2. Every \((\mathbb{Z}, V)\)-polytope has a polysimplicial subdivision.

Recall: a polytope is called polysimplicial if it is a product of rational simplices.

Let \(P \subset \mathbb{R}^n\) be a polytope. Let \(F\) be a 2-dimensional face of \(P\) with vertices \(v_1, \ldots, v_k\) and edges \(v_1v_2, v_2v_3, \ldots, v_kv_1\) (here \(uv\) denotes the segment with endpoints \(u, v\)). Let \(\eta : E(P) \to \mathbb{R}_{>0}\) be a function. We say that \(\eta\) is 2-balanced on \(F\) if
\[
\eta(v_1v_2)\frac{v_2 - v_1}{\|v_2 - v_1\|} + \eta(v_2v_3)\frac{v_3 - v_2}{\|v_3 - v_2\|} + \cdots + \eta(v_kv_1)\frac{v_1 - v_k}{\|v_1 - v_k\|} = 0.
\]
We say that \(\eta\) is 2-balanced (with respect to \(P\)) if it is 2-balanced on all 2-dimensional faces of \(P\).

Proposition 4.3.3. Let \(\eta : E(P) \to \mathbb{R}_{>0}\) be 2-balanced with respect to \(P\). Then there exists a unique up to translation polytope \(P' \subset \mathbb{R}^n\) and a graph isomorphism \(\psi : G(P) \to G(P')\) such that for each edge \(uv\) of \(P\), we have
\[
\psi(v) - \psi(u) = \eta(uv)\frac{v - u}{\|v - u\|}.
\]
4.3.3. For the function the polytope given by Proposition conclusion of the Proposition. It is immediate that Proof.

\[ \psi \]

The 2-balanced condition and the fact that 2-skeleton of a polytope has trivial first \( G \) Refining to polysimplicial. 4.3.5. \( \psi \)

\[ P \]

is the vertex set of a polytope \( P \). For \( P \) is 2-balanced with respect to \( P \) \( v \) \( \eta \) \( Q \) \( Q \)

\[ \ell \]

\[ 0 \]

\( \eta \) \[ 1 \]

\( \ell \)

\[ \ell \]

\[ V_{>0} := V \cap \mathbb{R}_{>0} \]. We need the following key result:

Proposition 4.3.6. For every \((\mathbb{Z}, V)\)-polytope \( P \subset \mathbb{R}^n \), there exists an independent set of \( \mathbb{Q} \)-elements \( \{\beta_1, \ldots, \beta_r\} \subset V_{>0} \) of \( V \) and \( S \)-polytopes \( P_1, \ldots, P_r \subset \mathbb{R}^n \) such that \( P = \beta_1 P_1 + \cdots + \beta_r P_r \).

Proof. Let \( E := E(P) \). For each \( e \in E \), fix a segment \( e_0 \subset \mathbb{R}^n \) such that \( e \) and \( e_0 \) are parallel and \( e_0 \) has endpoints in \( \mathbb{Q}^n \). Let \( \ell(s) \) denote the length of a segment \( s \). Define a function \( \ell_0 : E \to \mathbb{R} \) by

\[ \ell_0(e) = \ell(e)/\ell(e_0) \]

Then \( \ell_0(e) \in V \) for all \( e \in E \). Let \( \mathcal{L} = \{\ell_0(e) : e \in E\} \).

Note that \( \mathcal{L} \subset V_{>0} \). Since \( V_{>0} \) is an open half-space of the \( \mathbb{Q} \)-vector space \( V \) and \( \mathcal{L} \) is finite, we can find a \( \mathbb{Q} \)-basis \( \{\beta_1, \ldots, \beta_r\} \subset V_{>0} \) of \( V \) such that \( \mathcal{L} \) is contained in the positive \( \mathbb{Q} \)-linear span of \( \{\beta_1, \ldots, \beta_r\} \). For each \( e \in E \), let \( c_1(e), c_2(e), \ldots, c_r(e) \in \mathbb{Q} \) be the unique positive rational numbers such that

\[ \ell_0(e) = c_1(e)\beta_1 + \cdots + c_r(e)\beta_r \]

Now, for each \( i = 1, \ldots, r \), define \( \eta_i : E \to \mathbb{R} \) by \( \eta_i(e) = c_i(e)\ell(e_0) \). We claim that each \( \eta_i \) is 2-balanced with respect to \( P \). Indeed, suppose \( F \) is a 2-face of \( P \) with vertices \( v_1, \ldots, v_k \) and edges \( v_1v_2, v_2v_3, \ldots, v_kv_1 \). For each \( i \), let

\[
\ell_i := \eta_i(v_1v_2) \frac{v_2 - v_1}{\|v_2 - v_1\|} + \eta_i(v_2v_3) \frac{v_3 - v_2}{\|v_3 - v_2\|} + \cdots + \eta_i(v_kv_1) \frac{v_1 - v_k}{\|v_1 - v_k\|} = c_i(v_1v_2)(v_1v_2) + c_i(v_2v_3)(v_2v_3) + \cdots + c_i(v_kv_1)(v_kv_1)
\]
where \((uv)_0\) denotes the segment \((uv)\) oriented in the direction \(v-u\). Since each term on the right hand side of (3) is in \(\mathbb{Q}^n\), we have \(\epsilon_i \in \mathbb{Q}^n\) for all \(i\). Now,

\[
\sum_{i=1}^r \beta_i \epsilon_i = \left( \sum_{i=1}^r \beta_i c_i(v_1v_2) \right) (v_1v_2)_0 + \cdots + \left( \sum_{i=1}^r \beta_i c_i(v_kv_1) \right) (v_kv_1)_0
\]

\[
= \ell_0(v_1v_2)(v_1v_2)_0 + \ell_0(v_2v_3)(v_2v_3)_0 + \cdots + \ell_0(v_kv_1)(v_kv_1)_0
\]

\[
= (v_2-v_1) + (v_3-v_2) + \cdots + (v_1-v_k)
\]

\[
= 0.
\]

On the other hand, since \(\epsilon_i \in \mathbb{Q}^n\) for all \(i\) and \(\beta_1, \ldots, \beta_r\) are linearly independent over \(\mathbb{Q}\), this implies \(\epsilon_i = 0\) for all \(i\). Thus each \(\eta_i\) is 2-balanced.

Now, from the proof of Proposition 4.3.3, the polytopes \(P(\eta_1), \ldots, P(\eta_r)\) can be translated to have vertices in \(\mathbb{Q}^n\) and hence are \(\mathbb{Q}\)-polytopes. By Proposition 4.3.4, we have \(\beta_i P(\eta_1) + \cdots + \beta_r P(\eta_r) = P(\eta)\), where \(\eta = \beta_1 \eta_1 + \cdots + \beta_r \eta_r\). Note that \(\eta(e) = \ell_0(e) \ell(e_0) = \ell(e)\) for all \(e \in E\). Thus, by the uniqueness part of Proposition 4.3.3, it follows that \(P(\eta) = P\), as desired.

Proof of Lemma 4.3.2. Let \(P = \beta_1 P_1 + \cdots + \beta_r P_r\) be as in Proposition 4.3.6. Consider a fine mixed subdivision of \(P\) with respect to a dilated unimodular triangulations for \(\beta_1 P_1, \ldots, \beta_r P_r\), which we know exists by Knudsen-Mumford-Waterman [KKMS73].

Every cell of the subdivision is a product of simplices and is of the form \(\beta_1 C_1 + \cdots + \beta_r C_r\), where each \(C_i\) is a dilated unimodular simplex with \(S(C_i) \subseteq S(P_i)\). Since the vertices of \(P_i\) are in \(\mathbb{Q}^n\), each \(C_i\) is a \(\mathbb{Q}\)-polytope, and hence \(\beta_i C_i\) is a \((\mathbb{Z},V)\)-polytope. Thus \(\beta_1 C_1 + \cdots + \beta_r C_r\) is a \((\mathbb{Z},V)\)-polytope by Proposition 4.1.2, completing the proof.

4.4. From polysimplicial to polystable.

4.4.1. Roadblocks. Now, we are almost ready to prove Theorem 4.1.3 as well, but are hit with a roadblock that Proposition 4.3.6 put us in: Decomposition of \(P\) as Minkowski sum plays a crucial role in our approach, but a wrong choice of such a decomposition makes further polystable subdivision impossible.

Example 4.4.2. Let \(a, b > 0\) be two real numbers linearly independent over \(\mathbb{Q}\) and let \(V\) be their \(\mathbb{Q}\)-span in \(\mathbb{R}\). Consider the rectangle \(P\) obtained as the Minkowski sum of the segments \(P_1 = [(0,0), (a,a)]\) and \(P_2 = [(0,0), (b,-b)]\). Then \(P\) is a \((\mathbb{Z},V)\)-polytope, and the desired polystable subdivision cannot arise from a mixed subdivision, and in particular not from a unimodular triangulation of the underlying Cayley polytope.

4.4.3. A generalization of Knudsen-Mumford-Waterman to Cayley polytopes. Indeed, at this point, we would like to see a unimodular triangulation of the underlying Cayley polytope of \(P_1\) and \(P_2\), or at least of some of their integer multiples. The reason for this failure lies in the fact that the lattices generated by \(P_1\) and \(P_2\), respectively, form subgroups of infinite order in the ambient lattice \(\mathbb{Z}^2\). However, we can fix this if we restrict to Minkowski sums of co-compact \((\mathbb{Z},V)\)-polytopes, i.e., polytopes whose affine functions generate co-compact lattices. We indeed can restrict further for our purposes.
26 KARIM ADIPRASITO, GAKU LIU, IGOR PAK, AND MICHAEL TEMKIN

While seemingly innocent, it turns out that the key lemma is to triangulate Cayley polytopes without loss of index. Consider \((P_{[r]}) = P_1, \ldots, P_r\) a family of lattice polysimplices Minkowski dominated by a polystable \(d\)-polysimplex \(P\) (i.e. the normal fan of each member is refined by the normal fan of \(P\)).

**Lemma 4.4.4.** \(C(P_{[r]})\) has a unimodular triangulation.

*Proof.* We prove this statement in several steps of increasing generality. First, choose a distinguished vertex \(v_0 = 0\) of \(P\), and start from it a maximal path of linearly independent vertices connected by edges \((e_j) j \in [d]\). Then the polystable parallelepiped obtained as the Minkowski sum \(\sum e_j\) has a polystable subdivision by the simplices

\[
\text{conv}(v_0, v_0 + e_{\pi(1)}, \ldots, v_0 + \sum_{i=1}^d e_{\pi(i)})
\]

where \(\pi\) ranges over the permutations of \([d]\). This induces a unimodular triangulation of \(P\), and hence also the summands \(P_i\) and any of their multiples.

Assume now \((P_{[r]})\) is a constant family. Then the unimodular triangulation of a summand \(P'\) into unimodular simplices \(\Delta\) extends to a decomposition of \(C(P_{[r]})\) into Cayley polytopes \(C(\Delta_{[r]})\) (where \(\Delta\) is taken \(r\) times).

Now, we wish to understand what happens if we change the summands individually. We may assume that the individual summands are all smaller (i.e. contained in) than the summands of the constant family. Now, if we change one of the summands \(P_i\) to a smaller one, then we do so by iteratively projecting the lattice points along the vectors \((e_j)\) in their order from 1 to \(d\), to the affine span of the unique facet containing

\[
\sum_{j=1}^k e_j
\]

but not \(\sum_{j=1}^{k-1} e_j\), and keep the combinatorics intact. The resulting simplices will degenerate or remain unimodular. Repeating this procedure with all summands yields the desired. \(\square\)

We call the triangulation obtained a compressed lexicographic triangulation (short c-lex) of the Cayley polytope in question (induced by the linear order as described). Note that by restricting to one of the facets of \(P\), we pass to an associated Cayley polytope of that facet whose triangulation is c-lex as well.

Next, we show that if a polysimplex is not polystable, then we can improve the index as well, provided that one of the summands is cocompact (which, as we saw in the last section, is necessary). The proof of the lemma follows ideas of [HPPS], specifically their lemma 4.16. For a polyhedral complex \(X\) and a face \(F\), we call \(\text{st}_FX\) the star of \(F\) in \(X\), i.e. the minimal complex containing all faces containing \(F\).

If \((c_{[r]}) = (c_i)_{i=1, \ldots, r}\) is a vector of \(r\) positive integers, then we can consider the family \((c_{[r]})(P_{[r]}) = (c_i P_i)_{i=1, \ldots, r}\). Again, we argue by increasing generality, but separate the crucial case out for convenience.

**Lemma 4.4.5.** Consider a family of polysimplices \((P_{[r]})\) which is Minkowski dominated by its first summand \(P_1\). Assume \(P_1\) is cocompact, and that all facets of \(P_1\) are polystable (in the lattices of their affine spans), but \(P_1\) is not; its index is \(N > 1\). Then there exists a distortion factor \((\tilde{c}_{[r]})\) such that for every entrywise multiple
there is a subdivision of $\mathcal{C}(c_{[r]} P_{[r]})$ into Cayley polytopes of lattice polysimplices of strictly smaller index.

Moreover, the triangulation of $\mathcal{C}(c P_{[r]})$ is c-lex when restricted to the Cayley complex, and the refinement can be chosen to be regular.

**Proof.** Let $\tilde{P} = \sum_{j} \sigma_j$ denote a co-compact lattice polysimplex Minkowski equivalent to $P_1$ that generates a maximal lattice $\Lambda$, written as a sum of simplices $\sigma_j$.

Observe that for some $c_0 \leq \dim \tilde{P}$, $c_0 \tilde{P}$ has a triangulation into simplices of strictly smaller index than $N$, each adjoining an interior latticepoint $m$ to the lattice $\Lambda$. In particular, so does the Cayley-polytope of the $r$-fold copy of $c_0 \tilde{P}$.

Consider next the matrix $(\lambda_{(ij)})_{i \in [r], j \in [k]}$ of non-negative integers, then we denote by $P[(\lambda_{(ij)})]$ the Cayley polytope of the $r$ summands $\sum_{j} c_0 \lambda_{ij} \sigma_j$.

Observe first that if $(\lambda_{(ij)})$ is a $(0,1)$-matrix such that $\lambda_{(1j)}$ is the all-1-vector, then $P[(\lambda_{(ij)})]$ has a unimodular triangulation in $\langle \Lambda + m \rangle$ with c-lex boundary. This is achieved by simply triangulating the Cayley complex, and then coming with apex $m$.

Next, assume we modify some entry, say $\lambda_{(ab)}$, from 1 to some positive integer, say $\ell$. Then $\ell \sigma_b + \sum_{j \in [k] \setminus \{b\}} c_0 \lambda_{aj} \sigma_j$ is decomposed into $\left[\frac{\ell}{2}\right]$ concentric translated copies of

$$\alpha_k \sigma_b + \sum_{j \in [k] \setminus \{b\}} c_0 \lambda_{aj} \sigma_j,$$

where $\alpha_k$ goes over nonnegative even integers between 0 and $\ell$ (if $\ell$ is even) or odd integers (if $\ell$ is odd), with with vertices in $\Lambda$. These concentric copies are interlaced by translations of

$$\beta_k \sigma_b + \sum_{j \in [k] \setminus \{b\}} c_0 (\lambda_{aj} - 1) \sigma_j,$$

where $\beta_k$ ranges over the nonnegative odd integers (if $\ell$ is even) or even integers (if $\ell$ is even) between 0 and $\ell$. The space between these interlaced copies is triangulated unimodularly by Lemma 4.4.4. This triangulation extends to the Cayley polytope by the same lemma. \qed

**4.4.6. Proof of polystability.** We need to slightly modify the previous lemma to the following.

**Lemma 4.4.7.** Consider a Cayley triangulation $X$ of an $r$-fold family, a Cayley polytope of some dimension (say $d$) decomposed into Cayley polytopes that whose $r$ summands are Minkowski dominated by lattice polysimplices. Consider also a linear order on its $r$-dimensional Cayley simplices. Consider $F$ a non-polystable facet of $X$ (i.e. its index $j$ is larger than one in its affine span). Assume that one of the summands of $F$ is co-compact in the affine span of $F$.

Then there exists a distortion factor $(c_{[r]})$ such that for every entrywise multiple $c_{[r]}$, there is a subdivision of the family $c_{[r]} X$ into Cayley polytopes of lattice polysimplices such that each facet of $S = \text{st}_F X$ is subdivided into Cayley polytopes of strictly smaller index, and all other facets have unchanged index.

Moreover, the triangulation of $\partial \mathcal{C}(c S_{[r]})$ is c-lex (with respect to the linear order) and the refinement can be chosen to be regular.

**Proof.** A resizing of $X$ can be refined via Lemma 4.4.4 outside of $\text{st}_F X$. We therefore only have to discuss the situation in the star of $F$. For this, we can use the argument of the previous lemma, which we extend to facets of $X$ containing $F$. \qed
We are now ready to prove our main theorem.

**Proof of Theorem 4.1.3.** Following Lemma 4.3.2, we can assume that $P$ has a mixed subdivision into polysimplicial tiles arising from unimodular decompositions of Minkowski summands $(P_i)$. Unfortunately, corresponding summands may degenerate.

Hence, we change the summands by changing the independent set $\beta_1, \ldots, \beta_r$ in $V$ to a generic small linear transformation $\beta'_r$ (small enough so as not violate the positivity condition in the proof of Lemma 4.3.2). We then obtain a representation of the polysimplicial subdivision of $P$ as a mixed subdivision arising from combinatorially equivalent subdivisions of polytopes $(P'_i)$ generated from this basis. The individual facets arise therefore sections of Cayley polytopes of co-compact Minkowski-equivalent polysimplices in the $P'_i$, to which we can apply Lemma 4.4.7 repeatedly until the index of each summand in $L$ is one.

\[ \blacksquare \]

### 4.5. Polystable refinement, continued

We now turn to refinements of Theorem 4.1.3, the most important of which is the generalization to complexes.

#### 4.5.1. Polystable refinement of complexes

Given two polyhedral complexes $X$ and $X'$, we say that $X'$ refines $X$ if every cell of $X'$ is contained in a cell of $X$. We prove the following result.

**Theorem 4.5.2.** Let $X$ be a polyhedral complex where every cell is a $(\mathbb{Z}, V)$-polytope. Then there exists a polyhedral complex $X'$ which refines $X$ such that every cell of $X'$ is a $(\mathbb{Z}, V)$-polytope and a product of semistable simplices.

**Proof.** Let $L$ be the set of all edge lengths of all edges of $X$. As in the proof of Proposition 4.3.6, we can choose a $\mathbb{Q}$-basis $\{\beta_1, \ldots, \beta_r\} \subset V_{>0}$ of $V$ such that $L$ is contained in the positive span of $\{\beta_1, \ldots, \beta_r\}$. Also as in that proof, for each cell $C$ of $X$, there are $2$-balanced functions $\eta^C_1, \ldots, \eta^C_r$ with respect to $C$ such that $C = \beta_1 C(\eta^C_1) + \cdots + \beta_r C(\eta^C_r)$, where each $C(\eta^C_i)$ is a $\mathbb{Q}$-polytope. We may assume that each of these summands is subdivided in a regular unimodular triangulation as the Knudsen-Mumford-Waterman construction extends to triangulations of polyhedral complexes.

It is clear from the construction of the $\eta^C_i$ that when two cells $C, C'$ share an edge $e$, we have $\eta^C_i(e) = \eta^{C'}_i(e)$ for all $i$. Thus, for all cells $C$ and $C'$ which share a face $F$ and for all $i$, we have that $C(\eta^C_i)$ and $C'(\eta^C_i)$ share the common face (up to translation) $F(\eta^C_i)$, where $\eta^F_i$ is the common restriction of $\eta^C_i$ and $\eta^{C'}_i$ to the edges of $F$.

Now, suppose we have a function $f : S(X) \to \mathbb{R}$. For each cell $C$ of $X$ and for all $i = 1, \ldots, r$, let $\psi^C_i$ be the isomorphism from $G(\beta_i C(\eta^C_i))$ to $G(C)$ given by Proposition 4.3.3. Then for generic $f$, the functions $f \circ \psi^C_1, \ldots, f \circ \psi^C_r$ induce a fine mixed subdivision $X_C$ of $C$. As in the proof of Lemma 4.3.2, the cells of $X_C$ are all $(\mathbb{Z}, V)$-polystable and products of simplices. Moreover, for each face $F$ of $C$, the subdivision of $F$ given by $X_C$ is induced by $f \circ \psi^F_1, \ldots, f \circ \psi^F_r$, where $\psi^F_i$ is the isomorphism from $G(\beta_i F(\eta^F_i))$ to $G(F)$. Hence for all cells $C$ and $C'$ sharing a common face, we have that $X_C$ and $X_{C'}$ agree on that face. Thus the collection $\bigcup X_C$, where the union ranges over all cells $C$ of $X$, gives a polysimplicial subdivision. We can now transform it into a polystable subdivision using Lemma 4.4.7 as before.

\[ \blacksquare \]
4.5.3. Regular refinement. Recall the definition of regular subdivision from Section 4.2.4. In the case where \( X \) is a subdivision of a polytope, we can guarantee the refinement in Theorem 4.5.2 to be regular:

**Theorem 4.5.4.** Let \( X \) be a \((\mathbb{Z}, V)\)-subdivision of a polytope \( P \). Then there exists a regular polystable subdivision \( X' \) which refines \( X \). Moreover, there is a function \( f \) which induces \( X' \) such that \( P^f \) is a \((\mathbb{Z}, V)\)-polytope.

The proof follows from the following three propositions.

**Proposition 4.5.5.** For every \((\mathbb{Z}, V)\)-subdivision \( X \) of a polytope \( P \), there is a regular \((\mathbb{Z}, V)\)-subdivision which refines \( X \).

**Proof.** Without loss of generality, we may assume \( P \) is full-dimensional in \( \mathbb{R}^n \). Let \( \mathcal{A} \) be the collection of all affine hyperplanes spanned by facets of cells of \( X \). Then \( \mathcal{A} \) induces a subdivision \( X_A \) of \( P \) given by the collection of closures of connected components of \( P - \bigcup_{H \in \mathcal{A}} H \). Clearly this is a \((\mathbb{Z}, V)\)-subdivision, and every subdivision induced in this way by a collection of hyperplanes is regular. \( \square \)

**Proposition 4.5.6.** For every regular \((\mathbb{Z}, V)\)-subdivision \( X \) of a polytope \( P \), there is a regular polystable subdivision which refines \( X \).

**Proof.** By the proof of Theorem 4.5.2, there is a polystable refinement \( X' \) of \( X \) such that for every cell \( C \) of \( X \), the collection of cells of \( X' \) contained in \( C \) form a regular subdivision \( X_C \) of \( C \). For each cell \( C \) of \( X \), let \( f_C : S(X_C) \to \mathbb{R} \) be a function which induces \( X_C \). By the proof of Theorem 4.5.2, we can choose the \( f_C \) such that if two subdivisions \( X_C \) and \( X_{C'} \) share a vertex \( v \), then \( f_C(v) = f_{C'}(v) \). Hence, there is a function \( f' : S(X') \to \mathbb{R} \) such that for all \( C \), we have that \( f' \) restricted to \( S(X_C) \) is \( f_C \).

Let \( f_0 \) be a function which induces \( X \). Let \( f : S(X') \to \mathbb{R} \) be the function which restricts to \( f_0 \) on the vertices of \( X \) and equals 0 otherwise. Then for small enough \( \epsilon > 0 \), \( f + \epsilon f' \) induces \( X' \). Thus \( X' \) is regular. \( \square \)

**Proposition 4.5.7.** For every regular \((\mathbb{Z}, V)\)-subdivision \( X \) of a polytope \( P \), there is a function \( f \) which induces \( X \) such that \( P^f \) is a \((\mathbb{Z}, V)\)-polytope.

**Proof.** As in the proof of Theorem 4.5.2, there is a \( \mathbb{Q} \)-basis \( \{\beta_1, \ldots, \beta_r\} \subset V_{\geq 0} \) of \( V \) satisfying the following: For each cell \( C \) of \( X \), there are 2-balanced functions \( \eta^C_1, \ldots, \eta^C_r \) with respect to \( C \) such that \( C = \beta_1 C(\eta^C_1) + \cdots + \beta_r C(\eta^C_r) \) and each \( C(\eta^C_i) \) is a \( \mathbb{Q} \)-polytope. Moreover, the proof implies the following:

(i) For each \( i = 1, \ldots, r \) there are functions \( \eta_i : E(X) \to \mathbb{R}_{>0} \) such that for each cell \( C \) of \( X \), \( \eta_i \) restricted \( E(C) \) is \( \eta^C_i \).

(ii) Let \( \eta^P_i \) be the restriction of \( \eta_i \) to \( E(P) \). Then the collection \( X_i := \{C(\eta^C_i)\}_{C \in X} \) forms (after translation) a subdivision of \( P_i := P(\eta^P_i) \).

We now prove the following two lemmas.

**Lemma 4.5.8.** For each \( i \), \( X_i \) is a regular subdivision of \( P_i \).

**Proof.** Let \( f \) be a function which induces \( X \). Let \( E^f \) denote the set of lower edges of \( P^f \). (A lower edge is an edge which is a lower face, as defined in Section 4.2.4.) Fix \( i \), and define a function \( \eta^f_i : E^f \to \mathbb{R}_{>0} \) by

\[
\eta^f_i(e) = \eta_i(\pi(e)) \frac{\ell(e)}{\ell(\pi(e))},
\]
where \( \pi \) is defined as in Section 4.2.4. Now, suppose \( F \) is a 2-dimensional lower face of \( P^f \) with vertices \( v_1, \ldots, v_k \) and edges \( v_1v_2, \ldots, v_kv_1 \). Let

\[
\epsilon := \eta_i^f(v_1v_2) \frac{v_2 - v_1}{\|v_2 - v_1\|} + \eta_i^f(v_2v_3) \frac{v_3 - v_2}{\|v_3 - v_2\|} + \cdots + \eta_i^f(v_kv_1) \frac{v_1 - v_k}{\|v_1 - v_k\|}.
\]

We claim that \( \epsilon = 0 \). Indeed, we have

\[
\pi(\epsilon) = \eta_i(\pi(v_1v_2)) \frac{\pi(v_2) - \pi(v_1)}{\|\pi(v_2) - \pi(v_1)\|} + \cdots + \eta_i(\pi(v_kv_1)) \frac{\pi(v_1) - \pi(v_k)}{\|\pi(v_1) - \pi(v_k)\|} = 0
\]

because \( \pi(F) \) is a 2-face of \( X \) and \( \eta_i \) is 2-balanced. On the other hand, \( \epsilon \) is parallel to \( F \), and \( F \) lies in a hyperplane \( \{x \in \mathbb{R}^{n+1} : \phi(x) = c\} \) with \( \phi(0, \ldots, 0, 1) > 0 \). Hence, \( \pi(\epsilon) = 0 \) implies \( \epsilon = 0 \), as desired.

Thus, using the proof of Proposition 4.3.3, we can construct a polytope \( P' \) with vertex set \( S' \), lower edge set \( E' \), and lower graph \( G' = (S', E') \) such that there is a graph isomorphism \( \psi : G^f \to G' \), where \( G^f \) is the lower graph of \( P^f \), and

\[
\psi(v) - \psi(u) = \eta_i^f(\ell) \frac{v - u}{\|v - u\|}
\]

for every lower edge \( \ell \) of \( P^f \). The collection of projections of lower facets of \( P' \) under \( \pi \) is precisely the subdivision \( X_i \), as desired.

By construction, the subdivisions \( X_i \) can be translated to be \( \mathbb{Q} \)-subdivisions. We then have the following.

**Lemma 4.5.9.** For each \( i \), there is a function \( f_i \) which induces \( X_i \) such that \( P_i^f \) is a \( \mathbb{Q} \)-polytope.

**Proof.** For any function \( f : S(X_i) \to \mathbb{R} \), the condition that \( f \) induces \( X_i \) can be expressed as a system of linear equations and inequalities on its values: Namely, that for every \( (n \text{-dimensional}) \) cell \( C \) of \( X_i \), we have that \( C^f \) spans an \( n \text{-dimensional} \) affine subspace of \( \mathbb{R}^{n+1} \), and for every vertex \( v \) of \( X_i \) not in \( C \), \((v, f(v))\) lies strictly above this subspace (where “above” means in the \((0, \ldots, 0, 1)\) direction). Since \( X_i \) is regular, this system has a solution. Moreover, since \( X_i \) is a \( \mathbb{Q} \)-subdivision, all of the linear equations can be taken to have rational coefficients, and hence the system has a rational solution \( f_i \). Then \( P_i^f \) is a \( \mathbb{Q} \)-polytope, as desired.

We can now complete the proof. Let \( f_1, \ldots, f_r \) be as in the previous Lemma. Then \( \beta_1 P_1^f + \cdots + \beta_r P_r^f \) is a \((\mathbb{Z}, V)\)-polytope, and the collection of projections of lower facets of this polytope under \( \pi \) is precisely \( X \).

4.5.10. **Maps.** Recall that a \((\mathbb{Z}, V)\)-affine map is a map \( \mathbb{R}^n \to \mathbb{R}^m \) of the form \( x \mapsto Ax + v \), where \( A \in \mathbb{S}^{m \times n} \) and \( v \in \mathbb{L} \). A morphism of \((\mathbb{Z}, V)\)-polytopes \( P, Q \) is a map \( P \to Q \) induced by a \((\mathbb{Z}, V)\)-affine map. If \( X \) and \( Y \) are polyhedral subdivisions, a map \( X \to Y \) is a polyhedral map if the image of every cell of \( X \) is contained in a cell of \( Y \).

**Theorem 4.5.11.** Let \( P, Q \) be \((\mathbb{Z}, V)\)-polytopes, \( m : P \to Q \) a morphism of \((\mathbb{Z}, V)\)-polytopes, and \( Y \) a \((\mathbb{Z}, V)\)-subdivision of \( Q \). Then there exist regular polystable subdivisions \( X', Y' \) of \( P \) and \( Q \), respectively, where \( Y' \) refines \( Y \), such that the induced map \( m' : X' \to Y' \) is a polyhedral map.
Proof. By Theorem 4.5.4, there is a regular polystable subdivision $Y'$ which refines $Y$. Let $X := \{m^{-1}(C)\}_{C \in Y'}$. Then $X$ is a $(Z, V)$-subdivision of $P$. By Theorem 4.5.4, there is a regular polystable subdivision $X'$ which refines $X$. Then $X'$ and $Y'$ satisfy the conclusion of the theorem. \qed

5. Applications to log schemes

5.1. Monoidal subdivisions of log schemes. We will work with log structures defined in a topology $\tau$, which can be Zariski, étale or flat, though we are mainly interested in the first two cases. We only consider quasi-coherent integral log structures (recalled below).

5.1.1. Charts. A (global) affine chart for the log structure $M_X$ consists of an integral monoid $P$ and a homomorphism $P \to \Gamma(O_X)$ such that the associated log structure is $M_X$. Equivalently, one can present a chart as a strict morphism of log schemes $X \to \text{Spec}(\mathbb{Z}[P])$, or as a map of monoidal spaces $\pi : (X, M_X) \to \text{Spec}(P)$ such that the log structure associated with $\pi^*(P)$ is $M_X$. The latter approach can be conveniently globalized as follows: a monoscheme chart of $X$ is a morphism $\pi : (X, M_X) \to (Z, M_Z)$, where the target is a monoscheme and $M_Z$ is the log structure associated with $\pi^*(M_Z)$. In particular, the latter notion allows to work with disjoint unions.

5.1.2. Quasi-coherence. Recall that a log scheme is quasi-coherent if its log structure possesses charts $\tau$-locally. This happens if and only if it possesses a $\tau$-chart as follows: a strict morphism of log schemes $X' \to X$ which is a $\tau$-covering on the level of schemes and a monoscheme chart $X' \to Z$ for $M_{X'}$.

5.1.3. Monoidal pullbacks. The following result defines pullbacks of morphisms of monoschemes with respect to monoscheme charts.

Lemma 5.1.4. Assume that $X$ is a log scheme, $X \to Z$ is a monoscheme chart, and $Z' \to Z$ is a morphism of monoschemes.

(i) There exists a universal log scheme $X'$ over $X$ such that the composed map of monoidal spaces $X' \to Z$ factors through $Z' \to Z$. We call $X' \to X$ the pullback of $Z' \to Z$ and use the symbolical notation $X' = X \times_Z Z'$.

(ii) The pullbacks are compatible in the following sense: if $Y \to X$ is a strict morphism of log schemes then $Y \times_Z Z' = Y \times_X X'$.

Proof. In the affine case $X = X'$, $Z = \text{Spec}(P)$ and $Z' = \text{Spec}(P')$, we simply set $X' = X \times_{\text{Spec}(\mathbb{Z}[P])} \text{Spec}(\mathbb{Z}[P'])$. Clearly, this definition satisfies the universal property (i), and (i) holds for affine strict morphisms $Y \to X$. Furthermore, the affine construction is compatible with localizations of $P$ and $P'$, hence it uniquely extends to the case when $Z$ and $Z'$ are arbitrary monoschemes, and, again, it is clear this construction satisfies (i), and the pullback compatibility holds for strict morphisms $Y \to X$. \qed

5.1.5. Monoidal morphisms. We say that a morphism $X' \to X$ of log schemes is monoidal if $\tau$-locally it is a monoidal pullback. Concretely, this means that there exists a $\tau$-chart $Y \to X$, $Y \to Z$ such that the base change $X' \times_Y Y \to Y$ is the pullback of a morphism of monoschemes $Z' \to Z$. If, in addition, $Z' \to Z$ can be chosen birational, a partial subdivision, or a subdivision, then we say that $X' \to X$ is monoidally birational, a partial monoidal subdivision, or a monoidal subdivision, respectively.
5.1.6. Fans of log schemes. By a fan of a log scheme $X$ we mean a morphism of monoidal spaces $\overline{X} := (X, \overline{M}_X) \to F$ such that $F$ is a fan and $f^*(M_F) = \overline{M}_X$.

**Lemma 5.1.7.** Let $X$ be a quasi-coherent log scheme.

(i) Any monoscheme chart $X \to Z$ induces a fan $\overline{X} \to F = \overline{Z}$.

(ii) Conversely, any affine fan $\overline{X} \to F = \text{Spec}(P)$ is induced from an affine chart $X \to \text{Spec}(P)$ with $\overline{F} = P$.

**Proof.** Choose a point $x \in X$ and let $z \in Z$ be its image. Then $M_{X,x} \to \mathcal{O}_{X,x}$ is the log structure associated with the pre-log structure $M_{Z,z} \to \mathcal{O}_{X,x}$. The functor from pre-log structures to log structures modifies the units, but keep the sharpenings unchanged. Therefore, $\overline{M}_{X,x} = \overline{M}_{Z,z}$ and we obtain that $\overline{X} \to \overline{Z}$ is a fan. This proves (i).

For (ii), set $M = \Gamma(M_X)$. Then the affine fan is determined by the homomorphism of global sections $Q \to \overline{M}$. Setting $P = M \times_{\overline{M}} Q$ we obtain a homomorphism of monoids $P \to M$ whose sharpening is $Q \to \overline{M}$. It remains to show that the map $f: (X, M_X) \to (\overline{X}, \overline{M}_X)$ corresponding to $P \to M \to \Gamma(\mathcal{O}_X)$ is a chart. For this we should show that for any $x \in X$ with image $z = f(x)$ the log structure associated with $M_{Z,z} \to \mathcal{O}_{X,x}$ coincides with $M_{X,x}$, and it suffices to show that the sharpening of $M_{Z,z} \to M_{X,x}$ is an isomorphism. On the level of sets, $f$ coincides with the fan $X \to F$. Hence $\overline{M}_{Z,z} = \overline{M}_{F,z} = \overline{M}_{X,x}$, as required. □

5.1.8. Fan pullbacks. In general, there is no natural way to associate to a morphism of fans $h: F' \to F$ a pullback morphism of log schemes $X' \to X$, but the situation improves if there is a canonical way to lift $h$ to monoschemes.

**Theorem 5.1.9.** There is a unique up to unique isomorphism construction that given a fan $\overline{X} \to F$ and a birational morphism of fans $F' \to F$ outputs a birationally monoidal morphism $X' \to X$, whose source will be symbolically denoted $X' = X \times_F F'$, so that the following compatibility conditions are satisfied:

(i) If $Y \to X$ is a strict morphism, then $Y \times_F F' = Y \times_X X'$.

(ii) If $\overline{X} \to F$ lifts to a monoscheme chart $X \to Z$ with $\overline{Z} = F$, and $Z' \to Z$ is the birational lift of $F' \to F$ (Corollary 2.2.11) then $X' = X \times_Z Z'$.

**Proof.** It is easy to see that the question is local on $F$, so we can assume that $F = \text{Spec}(P)$. By Lemma 5.1.7(ii), the fan chart $\overline{X} \to F$ can be lifted to a monoscheme chart $X \to Z$ with $\overline{Z} = X$. By Lemma 2.2.10(i), the morphism $F' \to F$ lifts uniquely to a birational morphism of monoschemes $Z' \to Z$, and we set $X' = X \times_Z Z'$. Moreover, comparing different monoscheme charts and using uniqueness of liftings of $F' \to F$, we obtain that $X'$ depends only on $F' \to F$ and hence can be denoted $X' = X \times_F F'$. Clearly, this construction satisfies (ii), and pullback compatibility (i) reduces to its monoscheme analog from Lemma 5.1.4(i). □

The lifting from fans to monoschemes preserves (partial) subdivisions by Corollary 2.2.15. Therefore, the above proof also implies the following property of pullbacks:

**Lemma 5.1.10.** Keep notation of Theorem 5.1.9 and assume that $F' \to F$ is a subdivision or a partial subdivision. Then $X \times_F F' \to X$ is a monoidal subdivision or a monoidal partial subdivision, respectively.

The following remark will not be used, so we skip an easy justification.
**Remark 5.1.11.** It is easy to see that $X' = X \times_F F'$ is the universal log scheme over $X$ such that the map of monoidal spaces $\overline{X} \rightarrow F$ factors through $F'$. In particular, our notion of fan pullback agrees with that of Kato, and hence generalizes Kato’s definition in few aspects: log schemes are only assumed to be quasi-coherent and morphism of fans are only assumed to be birational.

5.1.12. Properties of monoidal pullbacks. Now we will check that certain properties of morphisms of fans or monoschemes are transformed to their scheme-theoretic analogs.

**Theorem 5.1.13.** Assume that $X$ is a quasi-coherent log scheme, and we are given either a monoschemes chart $X \rightarrow F$ or a fan $\overline{X} \rightarrow F$ of $X$. Assume, furthermore, that $f: F' \rightarrow F$ is a birational morphism and $h: X' = X \times_F F' \rightarrow X$ is the induced monoidally birational morphism.

(i) If $f$ is of finite type then $h$ is a logarithmically smooth morphism.

(ii) If $f$ is a subdivision (resp. a partial subdivision) then $h$ is proper (resp. separated).

**Proof.** Clearly, both claims are local on $F$. So, we can assume that $X' \rightarrow X$ is the pullback of a morphism of monoschemes $Z' \rightarrow \Spec(P)$. (In the case of fans, we use Lemma 5.1.7(ii) and Corollary 2.2.15 to lift fans to monoschemes.) Since $F$ is of finite type, $Z'$ is covered by open affines $\Spec(P_i)$, $1 \leq i \leq n$, where each $P_i$ is finitely generated over $P$. Therefore, $X' \rightarrow X$ is the pullback of a morphism $Y' \rightarrow Y = \Spec(\mathbb{Z}[P])$, where $Y'$ is glued from $Y_i = \Spec(\mathbb{Z}[P_i])$, $1 \leq i \leq n$.

The morphisms $Y_i \rightarrow Y$ are of finite type. Moreover, since $P^{\gp} = P^{\gp}_i$, these morphisms are automatically log smooth, and hence $X' \rightarrow X$ is log smooth, thereby proving (i).

Note that $Y$ and $Y'$ are integral with generic point $\Spec(K)$ for $K = \Frac(\mathbb{Z}[P^{\gp}])$, and hence in the properness or separatedness criteria for $Y' \rightarrow Y$ it suffices to consider the valuation rings $R$ with $K = \Spec(R)$. For example, see [Har77, Chapter II, Exercise 4.5] or [Tem11, Proposition 3.2.3] applied to $\Spec(K) \rightarrow Y' \rightarrow Y$.

Assume that $R$ is a valuation ring of $K$ such that $\Spec(K) \rightarrow Y$ factors through $\Spec(R)$. Then $R \cap P^{\gp}$ is a valuative monoid of $P^{\gp}$ containing $P$, and $P_i \subseteq R \cap P^{\gp}$ if and only if $\mathbb{Z}[P_i] \subseteq R$. Therefore, there is a one to one correspondence between the factorings of $\Spec(R) \rightarrow Y$ through $Y'$ and factorings of $\Spec(R \cap P^{\gp}) \rightarrow \Spec(P)$ through $Z'$. If $f$ is a subdivision (resp. a partial subdivision) then there exists precisely (resp. at most) one such factoring, and we obtain that $Y' \rightarrow Y$ is proper (resp. separated). This proves (ii). \qed

Given a log scheme $X$ let $X_{fr}$ denote the locus on which the log structure is trivial in the sense that $M_X|_{X_{fr}} = \mathcal{O}_X|_{X_{fr}}$.

**Corollary 5.1.14.** Any monoidal subdivision $f: X' \rightarrow X$ is a proper morphism, which is an isomorphism over $X_{fr}$. In particular, if $X_{fr}$ is dense then $f$ is a modification.

**Proof.** Since a morphism is proper if and only if its faithfully flat base change is proper, this follows from Theorem 5.1.13. \qed

5.2. Log varieties over valuation rings.
5.2.1. Notation. Fix, now, a valuation ring $\mathcal{O}$ and let $K$ be the fraction field. We assume that $\mathcal{O}$ is of height one and the group of values $V = K^\times/\mathcal{O}^\times$ is divisible. Without restriction of generality, we also fix an ordered embedding $V \hookrightarrow \mathbb{R}$. We provide $S = \text{Spec}(\mathcal{O})$ with the log structure given by $R = \mathcal{O} \setminus \{0\}$. Note that $\overline{R} = V_{\geq 0}$.

5.2.2. Log varieties. By a log variety over $S$ we mean a quasi-coherent log scheme $X$ over $S$ such that the underlying morphism of schemes $S \to X$ is flat of finite presentation and each homomorphism of monoids $\overline{R} \to \overline{M}_{X,x}$ is injective and finitely generated. By default we assume that the topology $\tau$ is étale. If $\tau$ is Zariski then we say that $X$ is a Zariski log variety.

For any $R$-monoid $P$ set $A_P := S \otimes_{\mathbb{Z}[\hat{P}]} \mathbb{Z}[P]$ with the log structure induced by $P$ over $S$. This is a Zariski log variety when $P$ is integral and $R \hookrightarrow P$ is of finite presentation. An arbitrary log variety $\tau$-locally admits a strict morphism to some $A_P$ as above. A log variety $X$ is called log smooth if $\tau$-charts $f_i : X_i \to A_P$, can be chosen to be étale morphisms.

Remark 5.2.3. For shortness we adopt this ad hoc definition of log smoothness. It is easy to see that one can only require in the definition that $f_i$ are smooth. Furthermore, if $X$ is log smooth then any $\tau$-chart $X' \to A_P$ is smooth.

5.2.4. Log stratification. By the log stratification of $X$ we mean the maximal stratification $X = \bigsqcup_i X_i$ such that the following condition holds: for any geometric points $x, y$ of $X$ over $X_i$, such that $y$ specializes $x$, the cospecialization homomorphism $\overline{M}_{X,y} \to \overline{M}_{X,x}$ is an isomorphism.

Lemma 5.2.5. Logarithmic stratification exists for any log variety $X$ over $S$, and it is compatible with any strict morphism $f : Y \to X$ in the sense that $f$ takes strata to strata. If $X$ is Zariski then its logarithmic stratification is the maximal stratification of $X$ such that $\overline{M}_X$ is constant along the strata.

Proof. The second claim and the compatibility with strict morphisms are obvious. Existence is established in three steps. First, each $A_P$ possesses such a stratification with strata of the form $V(q) \setminus \cup_{q \leq r} V(r)$, where $q \in \text{Spec}(P)$. We use here that $\text{Spec}(P)$, and hence also $\text{Spec}(P)$, is a finite set. Second, if $X$ possesses a chart $X \to A_P$, then the log strata of $X$ are the connected components of the preimages of the log strata of $A_P$. Third, an arbitrary log variety $X$ possesses a strict étale covering $X' = \bigsqcup_i X'_i \to X$ such that each $X'_i$ possesses a chart. The stratifications of $X'_i$ agree on $X' \times_X X'$ and hence define a stratification of $X$ as required. \hfill \Box

5.2.6. Canonical fans of Zariski log varieties. For any log variety $X$ over $S$ let $F(X)$ denote the finite set of log strata of $X$ provided with the natural specialization topology – a set is closed if it is closed under specializations. If $X$ is Zariski then we also provide $F = F(X)$ with a structure sheaf $\overline{M}_F$ such that if $z \in F$ then $\overline{M}_{F,z} = \overline{M}_{X,z}$ for any $x \in z$, and the cospecialization maps $\overline{M}_{F,z} \to \overline{M}_{F,z'}$ are the cospecialization maps $\overline{M}_{X,z} \to \overline{M}_{X,z'}$. Clearly, this defines a sheaf $\overline{M}_F$ whose pullback to $X$ is $\overline{M}_X$.

Lemma 5.2.7. For any Zariski log variety $X$ over $S$ the space $(F, \overline{M}_F)$ is a finitely presented fan over $\text{Spec}(\overline{R})$. In particular, $(X, \overline{M}_X) \to (F, \overline{M}_F)$ is a fan of $X$, that will be called the canonical fan of $X$. 

**Proof.** If \( X = A_F \) then \( F = \text{Spec}(P) \) and the claim is obvious. Since the log stratification is compatible with charts by Lemma 5.2.5, the general case follows easily. □

One can develop the theory further following the case of fs log schemes. We only indicate this direction without proofs, since it will not be used.

**Remark 5.2.8.** (i) In fact, the log structure is Zariski if and only if the map \( X \to F \) can be upgraded to a fan \( (X, \mathcal{M}_X) \to (F, \mathcal{M}_F) \) of \( X \). One can also give explicit criteria of this extending those from [Niz06, §2.1.2]

(ii) In general, one can provide \( F \) with a structure of a generalized fan analogous to generalized cone complexes from [ACP15].

5.2.9. Zariski subdivision. In order to deal with general log varieties we will prove that they can be modified to Zariski ones.

**Lemma 5.2.10.** Let \( X \) be a fine log scheme. Then there exists a monoidal subdivision \( X' \to X \) such that \( X' \) is a Zariski log variety.

**Proof.** If \( X \) is fs then this is proved in [Niz06, Theorem 5.4]. It remains to use that monoidal subdivisions are preserved by compositions and the saturation \( X_{\text{sat}} \to X \) is a monoidal subdivision. □

5.2.11. Approximation. The construction of a subdivision \( X' \to X \) in [Niz06, Theorem 5.4] is canonical, and it goes by blowing up ideals generated by certain indecomposable elements of the fs monoids \( \mathcal{M}_{X,x} \). This does not apply directly to a log variety \( X \) over \( R \) because the monoid \( \mathcal{M}_{X,x} \) is too large. It is unclear if there is a canonical Zariski subdivision in this case, though one can construct a non-canonical one by blowing up large enough ideals. Instead of working this out, we will reduce to the fine case using the following approximation result.

**Theorem 5.2.12.** Assume that \( \mathcal{O} \) is a valuation ring, and let \( \{R_i\}_{i \in I} \) denote the family of fine submonoids of \( R = \mathcal{O} \setminus \{0\} \). Let \( S \) and \( S_i \) denote \( \text{Spec}(\mathcal{O}) \) provided with the log structures \( R \) and \( R_i \), respectively. Then for any log variety \( X = (X, M_X) \) over \( S \) there exists \( i \in I \) and a morphism of fine log schemes \( X_i = (X, M_i) \to S_i \) with an isomorphism \( X = X_i \times_{S_i} S \), where the product is taken in the category of integral log schemes.

**Proof.** Assume first that \( X \) possesses an affine global chart \( P \to \Gamma(\mathcal{O}_X) \) with a finitely presented \( R \)-monoid \( P \). By Lemma 2.1.9, \( P = (P_j \oplus_{R_j} R)^{\text{int}} \) for a large enough \( j \) and an integral finitely generated \( R_j \)-monoid \( P_j \). Therefore, we can take \( i = j \) and \( M_i \) the log structure associated with \( R_i \to \Gamma(\mathcal{O}_X) \).

In general, there exists a strict étale covering \( \prod_{k=1}^n X_k \to X \) such that each \( X_k \) possesses a global affine chart. By the affine case, choosing \( i \in I \) large enough we can provide each \( X_k \) with a log structure \( M_{k,i} \) such that \( X_{k,i} = (X_k, M_{k,i}) \) is a fine log scheme and \( X_k = X_{k,i} \times_{S_i} S \). Moreover, by the second claim of Lemma 2.1.9, any two choices of \( M_{k,i} \) become isomorphic after increasing \( i \). Therefore, for a large enough \( j \geq i \) the log structures of \( X_{k,j} = X_{k,i} \times_{S_i} S_j \) agree on the products \( X_{k_1} \times_X X_{k_2} \) and hence give rise to a required fine log structure \( M_j \) on the whole \( X_j \). □

Now we can extend the Zariski subdivision theorem to log varieties over \( S \).
Theorem 5.2.13. Let $X$ be a log variety over $\mathcal{O}$. Then there exists a monoidal subdivision $X' \to X$ such that $X'$ is a Zariski log variety.

Proof. Find an isomorphism $X = X_i \times_S S$ as in Theorem 5.2.12. By Lemma 5.2.10 there exists a monoidal subdivision $X_i' \to X_i$ such that $X_i'$ is Zariski. Then $X' = X_i' \times_X X$ is a monoidal subdivision of $X$, and since $X' = X_i' \times_S S$, we also see that the log structure of $X'$ is Zariski. □

5.2.14. Monoidally polystable subdivisions. A log variety $X$ over $S$ is called monoidally polystable at a point $x \in X$ if the $R$-toric monoid $\mathcal{M}_{X,x}$ is polystable. If, in addition, $X$ is log smooth over $S$ at $x$ then we say that $X$ is polystable at $x$. Naturally, $X$ is monoidally polystable or polystable if it is so at all points.

Remark 5.2.15. By §2.3.10, $X$ is polystable at $x$ if and only if étale locally over $x$ it admits a strict étale morphism to a model polystable log variety of the form

$\text{Spec}(R[v_1^{\pm 1}, \ldots, u_m^{\pm 1}, t_{0,0}, \ldots, t_{0,n_0}, \ldots, t_{l,0}, \ldots, t_{l,n_l}]/(t_{1,0} \cdots t_{1,n_1} - \pi_1, \ldots, t_{l,0} \cdots t_{l,n_l} - \pi_l))$

with the log structure generated by $t_{ij}$ over $R$. So, on the level of schemes our notion of polystability over $S$ agrees with the one introduced by Berkovich in [Ber99, Section 1]. However, our definition works, more generally, with log schemes and addresses the case of a non-trivial horizontal log structure corresponding to $t_{0,0}, \ldots, t_{0,n_0}$.  

Theorem 5.2.16. Assume that $R$ is a valuation ring of height 1 whose group of values is divisible. Then for any log variety $X$ over $R$ there exists a monoidal subdivision $X'' \to X$ such that $X''$ is monoidally polystable. In particular, if $X$ is log smooth over $S$ then $X'$ is polystable over $S$.

Proof. First, by Theorem 5.2.13 there exists a monoidal subdivision $X'' \to X$ such that $X''$ is Zariski, and hence possesses a global fan $X'' \to F$ by Lemma 5.2.7. Then by Theorem 4.5.2 there exists a subdivision $F' \to F$ such that $F'$ is polystable. Since $F'$ is a global fan of the monoidal subdivision $X' = X'' \times_F F'$ of $X$, we obtain that $X'$ is monoidally polystable, as required. □

5.2.17. Polystable $p$-alteration theorem. Finally, we combine our main result with the $p$-alteration theorem to obtain the following application, where as in [Tem17, §4.1.2] an alteration means a proper, surjective, maximally dominating, generically finite morphism:

Theorem 5.2.18. Assume that $R$ is a valuation ring of height 1 and residual characteristic exponent $p$. Then for any variety $X$ over $R$ there exists an extension of valuation rings $R \subseteq R'$ and a $p$-alteration $X' \to X \otimes_R R'$ such that the extension $K'/K$ of fields of fractions is finite and $X'$ is polystable over $R'$.

Proof. Let $\overline{R}$ be an extension of $R$ to an algebraic closure $K$. If $X \otimes_R \overline{R}$ admits such an alteration $\overline{X}$, then the latter is induced from an alteration $X' \to X \otimes_R R'$ for a large enough finite extension $K'/K$ and $R' = \overline{R} \cap K'$. Also, it is easy to see that after an additional increasing of $K'$ one achieves that $X'$ is polystable over $R'$. So, we can safely assume in the sequel that $K = \overline{K}$.

Next, depending on the characteristics of $K$ and $R/\mathfrak{m}_R$, we present $R$ as the filtered union of subrings $R_i$, $i \in I$ finitely generated over $\mathbb{Q}$, $\mathbb{Z}_{(p)}$ or $\mathbb{F}_p$. In particular, $S = \text{Spec}(R)$ is the filtered limit of affine schemes $S_i = \text{Spec}(R_i)$. By
approximation theory (see [Gro67, IV, §8]), for a large enough $i \in I$, that we now fix, there exists an $S_i$-scheme $X_i$ of finite type such that $X = X_i \times_{S_i} S$.

By [Tem17, Theorem 1.2.9] there exist $p$-alterations $X'_i \to X_i$ and $S'_i \to S_i$ and log structures on $S'_i$ and $X'_i$, given by an appropriate divisor on $S'_i$ and its preimage in $X'_i$, such that $X'_i \to S'_i$ is log smooth. Since $K$ is assumed to be algebraically closed and $S'_i \to S_i$ is proper, the morphism $S \to S_i$ factors through $S'_i$. Furthermore, $\mathcal{M}_{S'_i} \to \mathcal{O}_{S'_i} \setminus \{0\}$, hence $S \to S'_i$ upgrades to a morphism of log schemes for the standard log structure $R \setminus \{0\}$ on $S$. Setting $X' = X'_i \times_{S'_i} S$ we obtain a log smooth log variety $X'$ over $R$. The morphisms $X' \to S$ and $X' \to X_i$ induce a morphism $X' \to X_i \times_{S_i} S = X$, which is easily seen to be a $p$-alteration too. Finally, by Theorem 5.2.19 we can further replace $X'$ by its modification (even monoidal subdivision) so that it becomes polystable over $S$.

\[ \square \]

Remark 5.2.19. In the case of residual characteristic zero, $X' \to X \otimes_R R'$ is a modification, and it suffices to use [AK00, Theorem 2.1] instead of [Tem17, Theorem 1.2.9].
