METHOD OF SAFE LANDING THE EMERGENCY QUADROCOPTER

Bohdan Blągikło, Yuriy Mochulsky
Ivan Franko Lviv’s National University, Faculty Electronics and Informational Technology, Department Radiofisics and Computer Technology

Abstract. By means of mathematical modelling, the main features of emergency landing of quadrocopter are determined. The results of simulate landings of the quadrocopter in cases of failure of one of four pairs of electric motor screw are given. The methods of safe landing of an unmanned quadrocopter in case of failure of one of four pairs of motor-screw are proposed. The basis of the proposed methods is to use a parachuting effect. Parachuting achieved by forced off the power of the motor, which is located at the opposite end of the same yoke as faulty motor. As a result, the vertical speed of the quadrocopter at the time of landing significantly decreases in comparison with the speed of free fall.

Keywords: quadrocopter, 3-axis gyroscope, 3-axis accelerometer, 3-axis magnetometer

METODA BEZPIECZNEGO LĄDOWANIA AWARYJNEGO KWADROKOPTERA

Streszczenie. Podstawowe cechy awaryjnego lądowania bezzałogowego kwadrokoptera zostały opisane metodami modelowania matematycznego. Zaproponowano metody bezpiecznego lądowania bezzałogowego kwadrokoptera w przypadku awarii jednego z czterech par silnik-winik. Podstawą proponowanej metody jest zastosowanie efektu spadochronu. Efekt spadochronu jest osiągany poprzez przymusowe wyłączenie zasilania silnika elektrycznego, który znajduje się na przeciwległym końcu belki z uszkodzonym silnikiem. W rezultacie prędkość pionowa kwadrokoptera w momencie lądowania znacznie maleje w stosunku do prędkości swobodnego spadania.

Słowa kluczowe: kwadrokopter, żyroskop 3-osiowy, 3-osiowy akcelerometr, 3-osiowy magnetometr

Introduction

In most articles on the problems of the quadrocopter flight, it is implicitly assumed that all four pairs of motor-screw and their control circuit are serviceable [5, 6, 8, 9]. In practice, often there are those or other faults in the sequence of links: the control circuit – the motor-screw. When a malfunction suddenly appears during the quadrocopter flight, then an emergency situation occurs.

In this article through mathematical modeling the basic features of quadrocopter emergency landings are considered. The results of mathematical modelling of quadrocopter emergency landings after the appearance of failure of one of the four electric motor screws are presented.

1. Simulation of the quadrocopter landings in the event of the failure of one of the four electric motor-screw

The volume of the whole article should include an even number of pages. The last page should be filled at least 50%. The author should make efforts to fill a total volume of pages with formatted article. We propose to write the text directly on this template, it will help you to meet the editorial requirements. Please do not break the text – do not use non-breaking spaces, hard (manual) line breaks, etc. The Editor reserves the right to editorial redaction of the submitted texts.

2. Equations

The mathematical model of a quadrocopter in flight in the event that all four pairs of the electric motor screw and the control scheme of them are regular are considered as two essentially different mathematical models. Actually the mathematical model of the quadrocopter is the UAV the inputs of which are the values of the voltage supply of electric motors, and the outputs are the altitude and angles of the roll, pitch and yaw. The mathematical model of the PD regulator is a system in which inputs a measured value from the sensors of height, the angles of the pitch, the roll and the yaw, and the microcontroller implements the PD algorithm and outputs the voltage values of the electric motors. The mathematical model of the quadrocopter in flight in the event that all four pairs of electric motor screw and the control scheme are useful, is described by the system of differential equations of the 16th order in the form of Cauchy [6].

In case of failure of one of the four pairs of electro-motor-screw quadrocopter, the following cases are possible: failure of the nasal steam motor-screw; failure of the tail-pair motor-screw; failure of the right pair of electric motor-screw; failure of the left pair motor-screw. The simulating of malfunctioning was performed by switching off the power of the faulty motor.

In order to solve the differential equations of the mathematical model of the quadrocopter, the implicit Runge-Kutta method TR-BDF2 was used (in the first stage of the equation integrated by the trapezium formula method, and in the second stage of the second order (differentiation formula back is used)).

The landing of the quadrocopter occurs after it has been suspended at a height of 50 m above the point with coordinates X = 0, Y = 0. The quadrocopter “nose” leads in the direction plus by axis X. In this case, the initial values of the angles of the pitch and the roll are zero, and the angle of yaw is 90°. Simulation of the failure of a specific pair of electric motor screw is carried out by assigning the supply voltage of the corresponding motor to a value of 0.0 V for all moments of time t => ta, where ta is the moment of failure of a specific pair of the electric motor-screw of the quadrocopter.

In all articles [5, 6, 8, 9] about the simulations, the quadrocopter motions are considered as movements of the material point of a mass m. But the quadrocopter has a complex spatial structure with certain dimensions. In order to see not only the movement of the center of the masses of the quadrocopter but also the idea of its rotation during an emergency landing, the movements of the two points of the quadrocopter, the center of mass and the nasal engine, were simulated. On Fig. 1 and on Fig. 4 the dashed line shows the trajectory of the center of the masses of the quadrocopter, and the squares of the trajectory of the movement of the nasal engine.

The results of mathematical modeling of the process of landing a quadrocopter in the event of a failure of one of the four pairs of the electric motor-screw of the quadrocopter are given in the form of a graph of trajectories of motion in Fig. 1. Trajectory 1 reflects the process of landing a quadrocopter in the failure of the nose pair of electric motor screw, and trajectory 3 – in the event of failure of the tail pair the motor-screw.

As can be seen from Fig. 2, after the accidental disconnection of the nasal electric motor, the pitch angle begins to decrease (the quadrocopter “lowers” the nose). As shown in [8], the nasal and tail motors create the momentum of the forces that the quadrocopter rotates in relation to the vertical axis clockwise (if viewed from the bottom). The right and left motors rotate the quadrocopter counter-clockwise relative to this axis. Therefore, when the nasal engine fails, the quadrocopter starts to rotate counter-clockwise. The Pitch and Yaw create a gyroscopic moment of forces, which begins to rotate the quadrocopter relative to the longitudinal axis, that is, there is a roll. Having made a little more than one turn relative to the transverse axis, the quadrocopter starts to rotate in the opposite direction, and in the future the Pitch
ranges in the vicinity of -150°. As for the longitudinal axis, the quadrocopter makes almost five turns in the negative direction and falls to the ground by the right engine.

As can be seen from Fig. 3, after the emergency shutdown of the tail motor, the angle of the roll begins to increase (quadrocopter "lowers" the tail). As indicated above, the nasal and tail motors rotate the quadrocopter relative to the vertical axis in the same direction. But the angular Pitch speed changed the direction of rotation to the opposite. Therefore, the gyroscopic moment of forces causes the quadrocopter's Roll in the opposite direction. By making more than one turn in a positive direction relative to the transverse axis, the quadrocopter starts to rotate in the opposite direction, and in the future the roll fluctuates in the vicinity of +150°. As for the transverse axis, the quadrocopter makes almost five turns in a positive direction and falls to the ground on the nasal motor.

Phase portraits for changing the angles of the roll, yaw and pitch after having turned off the left engine at the time \( t_a = 1 \) s, are shown in Fig. 6.

As can be seen from Fig. 6, after the emergency cut-off of the left electric motor, the angle of the roll begins to decrease (the quad-compressor "falls" to the left). At the same time, as a result of uncompensated moments of forces relative to the vertical axis, the quadrocopter starts to rotate clockwise. The gyroscopic moment of forces causes the quadrocopter Pitch. Having made a
2. Method of safe landing of quadrocopter with failure of one of the pairs of electric motor-screw

This article proposes a control method for the safe landing of a quadrocopter with a failure of one of the four pairs of electric motor-screw. The proposed method is to forcibly shut off the electric motor, which in paring with the already defective electric motor is located on the opposite end of the same console. This method uses the parachuting effect of the quadrocopter. Parachuting achieved by forced off the power of the motor, which is located at the opposite end of the same yoke as faulty motor. As a result, the vertical speed of the quadrocopter at the time of landing significantly decreases in comparison with the speed of free fall.

For example, the simulation results of a safe landing of an emergency quadrocopter with a height of 50 m over a point with coordinates X = 0, Y = 0. Quadrocopter at the same time "hangs" motionless (the angles of the pitch and the roll are zero). The main parameters of the quadrocopter: mass – 468 g, distance from the center of mass to the engine – 22.5 cm, EMC battery – 11.1 V.

Phase portraits of the angle of Yaw for the proposed method of safe emergency landing of the quadrocopter are shown in Fig. 7 (in the case of failure of the nose engine and the instantaneous disconnection case of the tail engine) and in Fig. 8 (in the case of failure of the left engine and instantaneous disengagement of the right motor).

Fig. 9 depicts a fragment of a safe emergency landing of a quadrocopter with a failure of the nasal engine and the instantaneous shutdown of the tail engine or with the cessation of the tail engine and the instantaneous disconnection of the nasal engine.

Fig. 10 depicts a fragment of a safe emergency landing of a quadrocopter with a failure of the right engine and the instant disconnection of the left engine or the failure of the left engine and instant disabling of the right engine.

For comparison: Fig. 11 shows the process of landing a quadrocopter in the event of a failure of one of the four pairs of motor-screw and the safe emergency landing of a quadrocopter with a failure of right engine and instantaneous shutdown of the left engine of a failure of left engine and instantaneous shutdown of the right engine.
3. Discussion of the simulation results of the landing process of an emergency quadrocopter

When free fall all four engines are off, the quadrocopter reaches the ground in just 6 seconds. The vertical component of the landing speed at the same time is 16.5 m/s. In case of refusal of one engine and working three remaining during the time of reduction, there are moments of forces concerning the axes of pitch, roll and yaw.

Table 1 shows the simulation results of the landing process of an emergency quadrocopter in case of failure of one of the four motor-screw pairs. Due to this, the rate of change does not change monotonously and the vertical component of the landing speed decreases to 12.7 m/s. The roll and pitch change randomly during a fall and at the time of landing they take on different values depending on the fault.

Table 1. The simulation results of the landing process of an emergency quadrocopter in case of failure of one of the four motor-screw pairs

| Engine failure | Pitch | Roll |Yaw| $V_x$/m/s | $V_y$/m/s | $V_z$/m/s |
|----------------|-------|------|---|-----------|-----------|-----------|
| nasal motor    | 180°  | 40°  | 10° | 0         | 1.47      | -12.7     |
| right motor    | -47°  | 180° | 160°| -1.05     | 0.59      | -12.7     |
| tail motor     | 180°  | -33° | 5°  | 0.03      | -1.44     | -12.7     |
| left motor     | 28°   | -170°| -180°| 1.1       | -0.6      | -12.7     |

In the event of a faulty nasal or tail motor, the quadrocopter falls to the landing site with screws down (pitch = 180°) and with a roll of 40° and -33°, respectively. Non-zero values of the horizontal velocity component at the moment of landing are an additional danger $V_x = 1.47$ m/s and $V_y = -1.44$ m/s, respectively. Depending on the friction coefficient at the landing site, the quadrocopter will still travel some distance along the ground.

In the event of a faulty right or left motor, the quadrocopter falls to the landing site with screws down (roll = 180°) and with a pitch of -47° and 28°, respectively. Non-zero values of the horizontal velocity component at the moment of landing are an additional danger $V_x = -1.05$ m/s, $V_y = 0.59$ m/s and $V_z = 1.1$ m/s, $V_z = -0.6$ m/s, respectively. Depending on the friction coefficient at the landing site, the quadrocopter will still travel some distance along the ground.

Table 2 shows the simulation results of the landing process of an emergency quadrocopter in case of failure of one of the four motor-screw pairs and simultaneously with the engine that is out of order, turn off the power of the electric motor, which is located at the opposite end of the same traverse as the defective electric motor.

Table 2. The simulation results of the landing process of an emergency quadrocopter in case of failure of one of the four motor-screw pairs and simultaneously with the engine that is out of order, turn off the power of the electric motor, which is located at the opposite end of the same traverse as the defective electric motor

| Engine failure | Pitch | Roll |Yaw| $V_x$/m/s | $V_y$/m/s | $V_z$/m/s |
|----------------|-------|------|---|-----------|-----------|-----------|
| nasal motor    | 0°    | 0°   |175°| 0         | 0         | -5.6      |
| right motor    | 0°    | 0°   |5°  | 0         | 0         | -5.6      |
| tail motor     | 0°    | 0°   |175°| 0         | 0         | -5.6      |
| left motor     | 0°    | 0°   |5°  | 0         | 0         | -5.6      |

If simultaneously with the engine that is out of order, turn off the power of the electric motor, which is located at the opposite end of the same traverse as the defective electric motor, then the time of fall is 11.7 s, and the vertical landing speed is 5.6 m/s. The horizontal components of the speed all the time will be zero, that is, the quadrocopter will fall vertically down. The roll and pitch during the fall are zero, that is, the quadrocopter will always land on the chassis. Due to the fact that in this case, not compensated moments of the forces of two opposite engines, the speed of rotation around the vertical axis at the time of landing will be 4.4 rad/s. This speed will create a distance of 22.5 cm from the center of mass of the acceleration 4.4 m/s².

4. Conclusion

The results of the conducted research determine the effectiveness and practical significance of the use of the proposed methods of safe landing of the quadrocopter, which in the flight unexpectedly refused one of the four pairs of propeller. To reduce the vertical component of the landing speed when the failure of one of the engines it is expedient as soon as possible to disconnect the voltage from the opposite engine, which is located on the opposite end of the console. In this case, the horizontal components of the speed are practically zero.
