Abstract—Collocation method based on barycentric rational interpolation (BRICM) is used in this article to study axisymmetric bending problems of circular thin plates in polar coordinates. Unknown function is approximated by barycentric rational interpolation and the discrete algebraic equations of differential equations are obtained by forcing the differential equations to satisfy the value of the discrete nodes. The boundary conditions are imposed by substitution method and the numerical solution can be obtained by solving the differential equations. Numerical calculation example demonstrates that the proposed method for circular thin plates bending problems has the merits of higher computation accuracy, convenient program, simple calculation formulations.

Keywords—axisymmetric bending problems; polar coordinates; barycentric rational interpolation; collocation method

I. INTRODUCTION

Circular plates are common in many structures such as nozzle covers, end closures in pressure vessels, pump diaphragms, turbine disks, and bulkheads in submarines and airplanes, etc [1]. The analytic method used to solve circular plate differential equation is impossible in many engineering designs and the engineering experiment is expensive and complicated. It is needed to study a high accuracy numerical method for analysis of bending of circular plate. When circular plates are analyzed, it is convenient to express the governing differential equation in polar coordinates.

At present, there are many methods to obtain the numerical solution of bending of circular plate such as finite difference method [2], finite element method [3], boundary element method [4], meshless method [5], differential quadrature method [6], Fourier differential quadrature method [7], homotopy perturbation method (HPM) [8], etc.

The meshless method also named as element free method (EFM) only needs nodal data and not date of element [5]. The current popular meshless method is that the algebraic equation of problem can be obtained through the approximate smooth function produced by the moving least square method [9]. The computation of EFM is very large. And it is more difficult to solve the problem with irregular region and it has instability to a large number of nodes by using differential quadrature method [6]. The computation of Fourier differential quadrature method is very large [7]. Based on the selected differential equations which have analytical solution, numerical solution can be obtained by HPM [8].

Although the above methods can solve the bending of plate, they have some disadvantages such as lacking of flexibility and a low accuracy [10].

Based on barycentric interpolation collocation method [11], this paper has established a barycentric rational interpolation collocation method (BRICM) for solving the axisymmetric bending problems of circular thin plate, and uses numerical example to verify effectiveness and computational accuracy of this proposed method. Due to the symmetry of circular thin plate, the two-dimensional problem is transformed into one-dimension problem, which greatly reduces the work time and improves the work efficiency.

Numerical calculation example show that BRICM has advantages of convenient use, higher efficiency, and higher accuracy compared with homotopy perturbation method (HPM) [10], meshless method and finite element method (FEM).

II. BRICM AND ITS DIFFERENTIAL MATRICES

First, given a function defined on the interval and the function values on the nodes are , the barycentric rational interpolation [12] of function is

\[ u(\rho) = \sum_{j=1}^{n} \frac{w_j}{\rho_i - \rho_j} / \sum_{j=1}^{n} \frac{w_j}{\rho_i - \rho_j} \] (1)

Where \( w_j = \sum_{i \in J_j} (-1)^{i-d} \prod_{k \in J_j \setminus \{i\}} \frac{l}{\rho_i - \rho_k} \), \( j = 1,2,\ldots,n \) is the barycentric rational interpolation weight, \( J_j = \{ i \in I : \rho_j - d \leq i \leq j \} \), \( d = 1,2,\ldots,n \) is an index set.

The barycentric rational interpolation of function \( u(\rho) \) can be simplified as
Young’s modulus, 

\[ \frac{E}{\rho} \]

is Poisson’s ratio of elasticity.

The governing equation of the circular plate axisymmetric bending of circular thin plates [14] in polar coordinates is as follows:

\[ \nabla^2 u + \frac{1}{r} \frac{d}{dr} \left( \frac{d}{dr} + \frac{u}{r} \right) = \frac{q}{D} \]

(6)

And in the extended form can be written as

\[ \frac{d^2 u}{dr^2} + \frac{2}{r} \frac{d u}{dr} - \frac{1}{r^2} \frac{d^2 u}{dr^2} - \frac{1}{r^2} \frac{du}{dr} = \frac{q}{D} \]

(7)

Where \( u = u(r) \) is the unknown deflection, \( q \) is uniform load, \( D = E t^2 / 12(1 - \nu^2) \), with \( E \) Young’s modulus, \( t \) the thickness of thin plate and \( \nu \) is Poisson’s ratio of elasticity.

The three boundary conditions of circular thin plate including clamped boundary, simply-supported boundary and free boundary are represented by \( \Gamma_1 \), \( \Gamma_2 \) and \( \Gamma_3 \) respectively in polar coordinates. \( \Gamma = \partial \Omega = \Gamma_1 \cup \Gamma_2 \cup \Gamma_3 \) is the boundary of the domain \( \Omega \) of circular thin plate with the boundary condition

\[ \begin{align*}
\Gamma_1: & \quad B_U \mathbf{u} = 0, \quad B_U \mathbf{u} = 0 \\
\Gamma_2: & \quad B_U \mathbf{u} = 0, \quad B_U \mathbf{u} = 0 \\
\Gamma_3: & \quad B_U \mathbf{u} = 0, \quad B_U \mathbf{u} = 0
\end{align*} \]

(12)

Boundary conditions are imposed to the algebraic equations with substitution method [15]. The barycentric rational interpolation collocation matrix of circular thin plate in polar coordinates can be obtained with clamped boundary (a), simply-supported boundary (b) and free boundary (c).

\[ \begin{bmatrix}
L[2] \\
B[2]
\end{bmatrix} \mathbf{u} = \begin{bmatrix}
F[2] \\
0
\end{bmatrix}, \quad \begin{bmatrix}
L[2] \\
B[2]
\end{bmatrix} \mathbf{u} = \begin{bmatrix}
F[2] \\
0
\end{bmatrix}, \quad \begin{bmatrix}
L[2] \\
B[2]
\end{bmatrix} \mathbf{u} = \begin{bmatrix}
F[2] \\
0
\end{bmatrix} \]

(13)

Where \( \begin{bmatrix}
L[2] \\
B[2]
\end{bmatrix} = \left( \mathbf{D}^{(2)} + \text{diag}(2/r) \mathbf{D}^{(1)} - \text{diag}(1/r^2) \mathbf{D}^{(1)} \right) \).
IV. NUMERICAL SOLUTION

One numerical calculation example is given in this article to verify the effectiveness and computational accuracy of BRICM. The calculation program is compiled by MATLAB. By use of BRICM and Chebyshev node, the numerical solution is obtained and compared with analytical solution. \( \mathbf{u}', \mathbf{u} \) are numerical solution column vector and analytical solution column vector, respectively. \( E_r = \| \mathbf{u}' - \mathbf{u} \| / \| \mathbf{u} \| \), \( E_a = \| \mathbf{u}' - \mathbf{u} \| \), are the relative error and absolute error respectively between numerical solution and analytical solution.

As shown in Figure 1, the radius is \( a = 5 \) m, \( t = 1 \) m, \( E = 2.0 \times 10^5 \) N / m², \( p = 6.0 \times 10^6 \) N.

\[ u'(r) = \frac{p(a^2 - r^2)}{64D} \left( \frac{5 + \nu}{1 + \nu} - r^2 \right). \]

For the calculation, computational domain is \( \Omega = [0, 5] \) and 11 nodes are selected in the direction of \( r \). The boundary is \( \Gamma_j \) in (11) and \( u_j = u(r_j = 5), j = 1, 2, ..., 11 \). By solving the (a) in (13), the BRICM numerical solution of bending of the plate can be obtained.

We can know that the numerical solution of FEM has a low accuracy and the numerical solution of HPM is highly consistent with analytical solution from the analysis of Fig.3(FEM result and HPM result compared with EXACT result) in [8]. Figure 2 shows that the results of BRICM and HPM are both highly consistent with EXACT results. Figure 3 shows that the accuracy of the BRICM result compared with EXACT result is \( 10^{-12} \).

V. CONCLUSIONS

In this article, BRICM is proposed for solving the bending of circular thin plate in polar coordinates. The method has simple calculation formulations and the calculation program is compiled by MATLAB. It is effective and convenient to many engineering designers to solving similar problem. Numerical example demonstrate that the proposed method has high computation accuracy with \( 10^{-11} \) and with the increasing of the number of nodes the accuracy is between \( 10^{-7} \) and \( 10^{-9} \). Compared with FEM, BRICM has higher computation accuracy, simple calculation formulations and dispenses with meshing and transforming irregular domain into a regular
domain according the coordinate transformation. The method has provided a new meshless method with high precision for bending problem of plate in engineering and is worth to be generalized to irregular plate problem and other engineering problems which need high accuracy.
