\textbf{Keywords:} Green solvents, palladium nanoparticles, glycerol ethers, DES, catalysis, hydrogenation.
ABSTRACT

Twenty-one green solvents, including glycerol-derived ethers, and their eutectic mixtures with two renewable ammonium salts, were used for the straightforward synthesis, stabilization and immobilization of palladium nanoparticles (Pd NPs). The nature of the solvent allows to tune the characteristics and properties of resulting catalytic systems in terms of particle size and morphology, stability, reactivity and recoverability. Pd NPs immobilized in glycerol-based solvents were applied in the catalytic hydrogenation of alkenes, alkynes and carbonyl compounds, as well as in the selective semihydrogenation of alkynes to alkenes. The optimal experimental parameters and the influence on the reactivity of the physicochemical properties of solvent, mainly the viscosity, were studied. Moreover, the most active and recoverable catalytic system, Pd NPs/N00Cl-100, was fully characterized both in liquid phase and at solid state, and its deactivation upon recovery was analyzed.

INTRODUCTION

Metallic nanocatalysts have attracted a huge interest in fields as nanomaterials, optics, catalysis and biomedicine, due to their electronic properties and high specific surface areas. Among all the transition metals, palladium has been one of the most applied in the synthesis of nanoparticles (NPs), offering interesting morphologies for catalytic purposes. In contrast to top-down methodologies that achieve the split of the metal by physical means, bottom-up approaches starting from metal salts and organometallic precursors allow a better control of the size, morphology and stability of the NPs in a reproducible way. However, NPs are unstable clusters that tend to agglomerate, increasing their size and reducing their active surface. For this reason, the enhancement of their stability is a key aspect that can be kinetically achieved by introducing steric,
electronic or electrosteric repulsion forces. Organic ligands, surfactants and polymers have been widely used for NPs stabilization. Once stabilized, NPs can be used directly or supported, blending the main features of both homogeneous and heterogeneous catalysts. The immobilization, either on solids or liquids, facilitates the recovery and reuse of metal NPs, and above all, increases their stability. Apart from solid supports such as clays, zeolites, oxides, polymers and carbonaceous materials, structurally organized liquid phases are being successfully applied for the immobilization of NPs.

In the last decade, the development of green solvents has enabled their intensive application owing to advantageous physicochemical properties such as both moderated volatility and flammability, biodegradability and low eco-toxicity. Among them, bio-based solvents such as polyols, water, ionic liquids (ILs), deep eutectic solvents (DES), and supercritical fluids, have already been used for the synthesis of NPs. In particular, glycerol has shown valuable properties for the preparation and stabilization of metallic species, due to its hydrogen-bond supramolecular structure. On account of the current bio-glycerine surplus, a plethora of DES have been described using glycerol as Hydrogen-Bond Donor (HBD), in combination with different ammonium salts such as choline chloride (ChCl). Some glycerol derivatives, including carbonates, ketals, esters and ethers, have also been studied as useful and versatile bio-solvents. In fact, green methods for the synthesis of monoethers and diethers of glycerol with multiple substitution patterns have been recently described. Thanks to their interesting physicochemical properties and their very low eco-toxicity, these glycerol-derived solvents are being used in novel applications, as chemical precursors, and also for replacing glycerol as the HBD component in eutectic solvents. Nevertheless, none of them has been used as solvent for the synthesis of NPs, and only for the immobilization of preformed Pd NPs in a very recent work.
Metal-catalyzed hydrogenation reactions of unsaturated compounds represent efficient and sustainable procedures, due to its total atom economy and low waste generation. Since the first Ni-catalyzed hydrogenation reactions described by Paul Sabatier, palladium, platinum and nickel catalysts have been profusely applied in industrial hydrogenations for the large-scale production of different petrochemicals, foods, drugs and fertilizers. In this context, the use of metal nanoparticles immobilized onto solid supports has demonstrated their interest, in particular for recycling purposes. However, liquid phases have been less considered as supports in the immobilization of NPs for catalytic applications.

To date, metal NPs in different ILs have been efficiently used in selective hydrogenations. In this case, the IL acts as the reaction medium, as well as the NPs stabilizer, ligand and support. Moreover, the selectivity can be modulated by changing the structure of the solvent. Despite their chemical similarity to ILs, DES have been barely applied in hydrogenation reactions. Just a few works have appeared such as the hydrogenation of methyl cinnamate in urea-carbohydrate mixtures using the Wilkinson’s catalyst, or the use of Pd NPs immobilized in choline-based DES in turn microencapsulated in polysilanes for the hydrogenation of unsaturated compounds. Finally, Gómez and co-workers have used polyols, mainly glycerol, as media for the immobilization of Ni NPs, Pd NPs and bimetallic Pd/Cu NPs for hydrogenation processes.

In this work, we study the utility of glycerol-derived solvents such as mono-, di-, and triethers of glycerol, as well as eutectic mixtures thereof, both as media for the sustainable synthesis, stabilization and immobilization of Pd NPs, and also for the selective hydrogenation of different unsaturated substrates. Morphology, stability, reactivity and recoverability of the catalytic systems have been analyzed, discussing the relevance of the nature of the solvent.

**EXPERIMENTAL SECTION**

The chemicals used in this work as reagent grade are listed in the Electronic Supplementary Information (ESI).† All the manipulations were performed using Schlenk techniques under argon atmosphere, unless otherwise stated. High-pressure reactions were carried out in a Top Industrie Autoclave. Conversions and yields were determined by Gas Chromatography coupled to Mass Spectrometry (GC-MS), using a Perkin Elmer Clarus 500 chromatograph equipped with a flame ionization detector (FID), and a Perkin Elmer Clarus MS 560 spectrometer as the mass detector. GC experimental conditions are detailed in the ESI.†

Glycerol-based solvents, catalytic systems and reaction products were fully characterized. Experimental and characterization details are gathered in the ESI.†

*Synthesis of the glycerol-based solvents*
Glycerol R00 monoethers were selectively prepared from glycidol and the corresponding alcohol by means of basic catalysis, following our previously described methodology.27 Glyceryl symmetric R0R diethers and non-symmetric R0R’ ones were synthesized starting from epichlorohydrin and the corresponding alcohol or alcohols, according to our previous works.29,30 Glycerol RRR triethers were obtained by methylation of the glycerol diether or monoether (1 mol) with iodomethane (1.4 mol), prior to ether deprotonation with NaH (1.2 mol) in dry THF (150 mL). After heating at 60 °C for 30-90 min, the reaction mixture was poured into cold water (133 mL) and quenched with HCl (0.2 mL, 0.3 M). Glycerol triethers were extracted with diethyl ether (3 × 66 mL), and the combined organic extracts were washed with an aqueous solution of sodium thiosulfate (5 wt%) to eliminate iodine traces. Then, the organic phase was dried over MgSO₄, filtered off and the diethyl ether was removed under reduced pressure to furnish the desired solvents. All the glycerol-derived solvents were completely purified by vacuum distillation and dried at 80 °C overnight under vacuum prior to use.

*Synthesis of the Pd nanoparticles immobilized in glycerol ethers*

In a Fisher–Porter bottle, 11.2 mg (0.05 mmol) of Pd(OAc)₂ and 111 mg of poly-N-vinylpyrrolidone (PVP, 10000 g·mol⁻¹) were completely dissolved, under argon atmosphere, in 5 mL of the glycerol ether dried as described above. That system was placed under vacuum, pressurized with hydrogen (3 bar), and stirred at 80 ºC for 10 h. Then, the resulting black colloidal solution (10 mM of Pd NPs) was cannulated and kept under argon prior to use in catalysis.

*Synthesis of the Pd NPs immobilized in glycerol-based DES*

In a Schlenk flask, 11.2 mg (0.05 mmol) of Pd(OAc)₂ were dissolved in 5 mL of the dried glycerol-based DES (ChCl-HBD, N00Cl-HBD) and stirred under argon at 80 ºC for 10 h. The black colloidal suspension obtained (10 mM or 1 mol% Pd) was kept under argon.
Isolation of the Pd NPs at solid state

After the above described synthesis, NPs in glycerol-derived solvents were transferred to a centrifugation tube and ethanol (5 mL) was added. Centrifugation was carried out at 3000 rpm for 5 min and then the solution was separated by decantation. This process was repeated twice with ethanol (5 mL), followed by two additional washings with acetone (2 mL). The remaining black powder was dried under vacuum at 80 ºC overnight. Elemental analysis (Pd determined by ICP-AES): Pd 88.9%, C 5.29%, N 0.95%, H 0.46% (in $\text{N00Cl-100}$ solvent).

General procedure for Pd-catalyzed hydrogenation reactions

The corresponding substrate (1 mmol) and the suspension of Pd NPs/glycerol-derived solvent (0.01–1 mol% Pd, 1 mL) were placed into a Fisher–Porter bottle (for hydrogenations working from 1 to 3 bar total pressure) or in an autoclave vessel (for hydrogenations working from 10 to 55 bar pressure), and stirred under argon atmosphere. The reaction mixture was put under vacuum and pressurized with hydrogen at the desired pressure. The system was stirred and heated at 80 ºC in a silicone oil bath for the specified reaction times. Then, the reaction system was cooled down to room temperature and then depressurized. The organic compounds were extracted with $n$-pentane (5 × 5 mL) at 40 ºC using vigorous stirring and periods of 15 min between each extraction. Purification of products was carried out by column chromatography or Kugelrohr distillation. Upon extraction of the organic products, the catalytic system was dried at 80 ºC under vacuum for 5 h prior to a new run.

RESULTS AND DISCUSSION

Selection and synthesis of the glycerol-derived solvents

As we have previously described, a great variety of differently substituted glycerol ethers can be eco-friendly synthesized in order to achieve a portfolio of renewable solvents with interesting
physicochemical properties. Some features of these green media such as their low eco-toxicity, low volatility, viscosity and high solubilizing ability for organic and inorganic compounds, encouraged us to use them for the synthesis of original catalytic systems based on palladium nanoparticles immobilized in liquid phases (Pd NPs/solvent). With this aim, the properties of the glycerol-derived medium not only allow the reduction of the palladium salt used as zero-valent Pd NPs precursor owing to the solubilization of H₂, but also enable the formation and stabilization of the metal NPs. Given the importance of Pd nanocatalysts towards surface-assisted reactions, we decided to apply the Pd NPs/solvent systems in different hydrogenation catalytic processes. In addition, the solubility of organic substrates and the recovery of reaction products from the glycerol-based reaction medium was also assessed in terms of simple manipulation and high reproducibility.
Figure 1. Selection of glycerol-derived solvents for the synthesis of immobilized Pd NPs and their application in catalysis. For eutectic solvents (ChCl-R00, N00Cl-R00, N00Cl-100-3F03F) plausible intermolecular interactions are highlighted in orange.

Taking all these aspects into consideration, a selection of different glycerol-derived bio-solvents is reported herein. As shown in the Scheme 1, glycerol (000), glyceryl monoethers (R00), diethers (symmetric R0R and non-symmetric R0R’) and triethers (RRR), as well as their eutectic mixtures with two bio-based ammonium salts, namely choline chloride (ChCl) and \( N,N,N\)-triethyl-2,3-
dihydroxy-propan-1-aminium chloride (N00Cl, see Scheme 1) were chosen. With this purpose, glycerol ethers bearing differently longed, branched and fluorinated R alkyl chains were synthesized. More specifically, the selected substituents were methyl groups in compounds 100, 101, 103i and 111, ethyl group in monoether 200, 2,2,2-trifluoroethyl chain in compounds 3F00, 3F03F and 3F13F, isopropyl chain in compounds 3i00 and 103i, and butyl chain in compounds 400 and 414 (see Figure 1).

On the other hand, for the preparation of the eutectic solvents, glycerol (000) and the glyceryl monoethers 100, 3i00 and 3F00 were used as the HBD component in combination with the two above mentioned salts, ChCl and N00Cl, as the HBA component, according to a 1:2 HBA/HBD molar ratio. Also, the ternary mixture N00Cl-100-3F03F, including the symmetric diether 3F03F, was prepared in a 1:1:1 molar ratio (see Figure 1).

Synthesis and characterization of the Pd NPs immobilized in glycerol ethers

In this work, Pd NPs were synthesized by the reduction of a palladium precursor, Pd(OAc)$_2$, in the solvent also acting as the immobilization liquid support. Glycerol (000), glycerol monoethers (100, 200, 3F00, 3i00, 400), glyceryl diethers (101, 103i, 3F03F), and glycerol triethers (111, 3F13F, 414) as solvents, as well as PVP as the stabilizer of the nanoparticles, were used.

Under mild conditions, at a hydrogen pressure of 3 bar and a temperature of 80 °C, the reduction of Pd(II) could be evidenced in the glycerol-derived media after 30 minutes, thanks to a color change of the resulting suspension, from orange to Pd(0) black (Scheme 2). In order to guarantee the full Pd reduction and optimal nucleation and growth of the PVP-Pd NPs, a standard reaction time of 10 hours was applied. In all the cases, using this synthetic procedure, black Pd NPs homogeneous suspensions with a high stability over time were formed. It is noteworthy to mention
that, in these media, the use of molecular hydrogen permits the palladium reduction, avoiding the oxidation of the glycerol-derived solvent.\textsuperscript{17,20}

\textbf{Scheme 2.} Synthesis of PVP-Pd NPs immobilized in glycerol ethers.

Transmission Electron Microscopy (TEM) analyses of these colloidal suspensions in glycerol ethers revealed spherical-shaped and well-dispersed Pd NPs (Figure 2). However, in the case of pure glycerol (000), the dispersion and homogeneity of the NPs were limited by its high viscosity (1200 cP versus 0.7–68 cP for the studied glycerol ethers at room temperature). All TEM micrographs and size distributions are detailed in the Supplementary Information, except for solvents 101 and 111, which could not be recorded in liquid media due to the higher volatility of both solvents. Interestingly, the amount and mean diameter of NPs showed a direct dependence with the nature of the glycerol-derived solvent used in the synthesis. In general, NPs prepared in more polar and viscous media increased their particle size. As it can be observed in Figure 2, along the sequence of polarity $3F03F < 100 < 3F00$, the mean particle size was respectively 1.3, 1.4 and 1.8 nm, albeit the relative large size distributions. When comparing the influence of the polarity and hydrogen bond ability of the solvent on the morphology of the synthesized NPs, using two differently substituted glycerol ethers such as $3F00$ and $3F03F$, it can be observed that the higher polarity and HBD ability of the monoether seems to be related to the formation of NPs presenting
higher mean sizes. Other aspects with minor influence on polarity, such as the ramification or the length of the ether alkyl chain, did not seem to have a significant influence on the NPs shape or size. For instance, in the cases of using 200 and 3i00, with a similar polarity, both solvents provided similar sized Pd NPs (1.5 ± 0.7 nm).

Figure 2. TEM micrographs and size distributions of PVP-Pd NPs immobilized in glycerol (000) and in three selected glycerol-derived solvents: 100, 3F00 and 3F03F.

*Synthesis and characterization of the Pd NPs immobilized in glycerol-derived DES*

The synthesis of Pd NPs in the glycerol-derived DES, using the same palladium precursor, was achieved by heating the mixture at 80 ºC under argon atmosphere in the absence of any additional stabilizers (Scheme 3). The ionic character and supramolecular arrangement via hydrogen bond in the eutectic solvents provided the NPs stabilization, acting the DES both as a liquid support and electrosteric stabilizer.
As it has been recently described, the small amounts of water present in glycerol or in these hygroscopic solvents would be responsible for the reduction of palladium(II) into zero-valent palladium species.\textsuperscript{46–48} The resulting Pd NPs black colloidal suspensions obtained using this straightforward procedure were stable. In particular, NPs synthesized in these glycerol-derived eutectic media showed different morphologies, populations and size distributions than in the case of using glycerol ethers (Figure 3). It can be observed that the nature of the medium has a bigger influence on the morphology of the synthesized Pd NPs, compared to the case of using glyceryl ethers. Hence, the selection of the solvent becomes an interesting tool for the design of metal NPs.
Figure 3. TEM micrographs of Pd NPs immobilized in six glycerol-derived eutectic solvents: N00Cl-000, N00Cl-100, N00Cl-3F00, N00Cl-100-3F03F, ChCI-3F00 and N00Cl-3i00, with their corresponding size distribution diagrams.

Pd NPs synthesized in fluorinated media, such as N00Cl-3F00 and ChCl-3F00, presented bigger mean diameters (ca. 2.2 nm) than in the case of the less polar solvents, i.e. 1.8 ± 0.9 nm for N00Cl-100 and 1.9 ± 0.9 nm for N00Cl-3i00. In addition, the high viscosity of the solvent also influenced the Pd NPs dispersion. An inhomogeneous distribution of nanoparticles in solvents N00Cl-000 and N00Cl-3F00, with viscosity values of 2693 and 553 cP respectively, was observed. Although similar particle diameters and size distributions were found for Pd NPs synthesized in DES
composed of the same glyceryl ether and different HBA salt, an influence of the nature of the ammonium salt on the NPs stability was identified. Thus, the presence of ChCl instead of N00Cl triggered some palladium agglomeration in the case of solvents ChCl-000, ChCl-3i00 and ChCl-3F00. Nevertheless, when using the fluorinated ether 3F00, similar trends were observed with both ammonium salts. Moreover, Pd NPs in N00Cl-100-3F03F showed a good dispersion of homogeneous particles with an average size of 2.0 ± 0.8 nm. The interest of these ternary mixture systems is based on the possibility of fine tuning the characteristics of metal NPs for specific catalytic applications. As expected, size resulted intermediate between those of N00Cl-100 and N00Cl-3F00, as a consequence of the intermediate properties values of this medium.

In order to evidence the structure of these immobilized Pd NPs, Pd NPs/N00Cl-100 was chosen as a homogeneously dispersed nanoparticles suspension in a DES for full characterization both in liquid phase and solid state (isolated by centrifugation from the corresponding colloidal solution). FT-IR analysis of Pd NPs at solid state suggested the presence of remaining solvent N00Cl-100 in the isolated NPs (see Figure S21), as a result of the strong interaction between the ionic solvent and palladium during the Pd NPs synthesis, thus demonstrating the major role of DES as electrosteric stabilizer. Both elemental and ICP-AES analyses showed a consistent palladium percentage (ca. 89%). As it could be expected, the rest of the mass seems to correspond to the above mentioned solvent N00Cl-100 stabilizing the NPs. As showed in Figure 4, X-ray Photoelectronic Spectroscopy (XPS) survey spectrum evidenced that palladium was in a zero-valent oxidation state (experimental values: 335.7 and 341.0 eV versus 335.4 and 340.3 eV for bulk Pd(0) 3d_{5/2} and 3d_{3/2} peaks, respectively). Furthermore, the XPS analysis revealed a N/Cl ratio of 3:8 (see Table S1 in the ESI). This fact could be explained by the partial degradation of
the ammonium salt of DES (N00Cl), in form of volatile amines (Hofmann elimination), while X-ray irradiation.

**Figure 4.** High Resolution XPS spectrum of Pd NPs/N00Cl-100 at solid state for Pd(0) region.

Powder X-Ray Diffraction (PXRD) analysis allowed to calculate a crystallite size of 3.9 ± 0.9 nm for Pd(0), which was consistent with the mean diameter of 3.3 ± 2.1 nm calculated at solid state using TEM microscopy (see Figure S19 and Figure S22 in the ESI). The five main crystallographic diffraction planes of crystalline Pd(0) can be appreciated in Figure 5 (blue lines). Experimental crystallographic data suit to the face centered cubic structure of Pd NPs.46

*Pd-catalyzed hydrogenation reactions*

Pd NPs immobilized in the glycerol-based bio-solvents, including glycerol, glyceryl ethers and their derived DES, were applied in the catalytic hydrogenation of different functional groups. Experimental parameters were optimized for the chosen benchmark hydrogenation of (E)-4-phenylbut-3-en-2-one (1, Scheme 4). Among them, catalyst amount, hydrogen pressure, temperature, reaction time and solvent volume were considered.

Scheme 4. Benchmark hydrogenation reaction of (E)-4-phenylbut-3-en-2-one (1), catalyzed by Pd NPs immobilized in glycerol-based solvents.

Table 1 gathers the conversions of (E)-4-phenylbut-3-en-2-one (1) catalyzed by Pd NPs immobilized both in glycerol (000, Table 1, entries 1–5) and in glycerol monoether 100 (Table 1, entries 6–10). For all the reactions, the only product obtained was 4-phenylbutan-2-one (1H), with isolated yields from 75% to 92% when full conversions were reached, by extraction with n-pentane as described in the experimental section. As it can be seen, the mildest reaction conditions affording the complete hydrogenation of the substrate in glycerol were obtained using a 0.1 mol% palladium loading and 1 bar H₂ pressure, at 80 °C for 2 h (Table 1, entry 4). Lower palladium loadings, temperature and reaction time provided partial conversions (Table 1, entries 1–3, 6 and 7). Interestingly, in the case of using the system Pd NPs/100, total conversion and selectivity could
be achieved with a lower palladium loading (0.05 mol% or 0.5 mM Pd). For this reaction medium, the best experimental conditions were 1 bar H₂, heating at 80 °C for 2 h (Table 1, entry 8).

**Table 1.** Influence of the reaction conditions in the hydrogenation of (E)-4-phenylbut-3-en-2-one catalyzed by Pd NPs immobilized in glycerol (000) and 100.

| Entry | Pd load (mol%) | Time (h) | Conversion (%) | TON (TOF, h⁻¹) |

*Reactions conditions: The substrate (1 mmol) was dissolved in the colloidal solution (1 mL) of preformed Pd NPs in glycerol (000) or 100 solvent in a Fisher-Porter vessel. The vessel was placed under vacuum prior to its filling with H₂ (1 bar), sealed and heated at 80 °C for 30 minutes unless otherwise stated. The reaction crudes were extracted using n-pentane. Conversion was determined in duplicate by GC and NMR using n-decane as internal standard. Selectivity was 100% for all the reactions.*

Therefore, Pd NPs immobilized in glycerol monoether 100 showed better activity than in glycerol. Slight activity differences in terms of catalytic turnover number and frequency could be observed between NPs immobilized in glycerol and 100 (TON 1000 vs 1160; TOF 2000 h⁻¹ vs 2320 h⁻¹; Table 1, entries 1 and 7, respectively). This can be attributed to the higher population of
smaller Pd NPs in the case of using the glycerol ether, which probably would increase the total active surface palladium and hence the catalytic activity.

The influence of the reaction solvent was also assessed in order to determine the most active Pd NPs/solvent system. Thus, we evaluated the catalytic activity at a shorter reaction time (30 min, see Table 2). Also, catalytic systems were recovered after the reaction and reused in a second run with the aim of evaluating their stability. In the first run, full conversions were achieved in only 30 minutes reaction time when using Pd NPs immobilized in glycerol ethers, both monoethers 200, 3i00 and 3F00 (Table 2, entries 3–5) and diether 3F03F (Table 2, entry 6). When comparing Pd NPs/DES systems, NPs immobilized in mixtures of glycerol ethers with N00Cl (Table 2, entries 11–14) led to better yields than mixtures with ChCl (Table 2, entries 8 and 9). In the case of using glycerol (Table 2, entry 1) and mixtures of ethers with ChCl, conversions not higher than 50% were observed. In addition, Pd NPs suspended in mixtures of glycerol with both ammonium salts (ChCl-000 and N00Cl-000, Table 2, entries 7 and 10 respectively) provided worse results than using their respective glycerol ether mixtures (ChCl-R00 and N00Cl-R00). In terms of recycling, only Pd NPs/N00Cl-100 gave excellent conversion and selectivity in the second run. Thus, this system showed the highest TON and TOF values (3920, 3920 h⁻¹). For the rest of the catalytic systems, conversions did not exceed 43% in the second run.

**Table 2.** Hydrogenation of (E)-4-phenylbut-3-en-2-one (1) catalyzed by Pd NPs immobilized in different glycerol-based solvents (two runs are shown).

\(^a\) Reaction conditions: The substrate (1 mmol) was dissolved in the colloidal solution of Pd NPs/glycerol-based solvent (1 mL, 0.5 mM Pd, 0.05 mol%), prior to the pressurization with 1 bar H\(_2\) heating at 80 °C for 30 minutes. \(^b\) Conversion was determined by GC-MS and NMR using \(n\)-decane as standard. Selectivity was 100% in all the cases except with 200 (86%). \(^c\) Isolated yields. \(^d\) Accumulated TON in two runs is the same value than average TOF in h\(^{-1}\).

The chemical nature of the solvent determines its capacity of solvating reagents, probably having an effect on the reaction manifolds. In this case, no solubility limitations of the organic compounds are considered a priori, as both glycerol ethers and their derived eutectic solvents display a wide range of polarity and hydrophobicity values.\(^{32,34}\) It is also interesting to remark the full selectivity observed with all these systems, precluding the reduction of carbonyl groups under mild reaction conditions. On top of that, the hydrogen bond network in the studied solvents guarantees the solvation of the palladium species involved in the catalytic process.\(^{35}\) To our knowledge, no information about the solubility of H\(_2\) in either of the glycerol-derived solvents is available, with
the exception of pure glycerol.\textsuperscript{15} Due to the high reactivities observed with these catalytic systems, the solubility of H\textsubscript{2} seems not to be a limiting parameter in the case of the studied solvents.

In a previous work, it has been demonstrated that the high viscosity of glycerol (with a dynamic viscosity of 31.9 cP at 80 °C) hinders the diffusion of both reagents and catalyst.\textsuperscript{35,48} This can be also a key point in order to explain the reactivity diminution observed in the hydrogenation reaction of substrate 1 from the glycerol ether systems (displaying a viscosity of 1.6 – 4.7 cP at 80 °C) to glyceryl ether-derived DES (12.5 – 21.4 cP at 80 °C), and even more for the DES composed of pure glycerol (23.1 and 55 cP for ChCl-000 and N00Cl-000, respectively, at 80 °C).\textsuperscript{34} The representation of the accumulated TON values versus the dynamic viscosity of the solvent (at the reaction temperature, 80 °C) in Figure 6 evidences this effect for each family of glycerol-derived media.

![Figure 6](image.png)

\textbf{Figure 6.} Relationship between the catalytic activity (accumulated TON in 2 cycles) of the systems \textbf{Pd NPs/solvent} in the benchmark hydrogenation reaction and the dynamic viscosity of the solvent (in cPs or mPa·s at 80 °C).
For instance, along the growing viscosity sequence $\text{N00Cl-100} < \text{N00Cl-3i00} < \text{N00Cl-3F00} < \text{N00Cl-000}$, the inverse trend in the catalytic productivity ($3920 > 1940 > 1880 > 900$) can be observed. A similar behavior in the case of mixtures with $\text{ChCl}$ and in the case of glyceryl ethers can be also implemented. Other physicochemical properties such as density, surface tension, refractivity or heat capacity of the solvent have also been considered.\(^\text{34}\) In the case of surface tension, a weak relationship with reactivity was found, probably due to the same reasons above explained for viscosity.

In addition to the properties of the reaction medium, size and morphology of Pd NPs directly impact on the catalytic reactivity.\(^\text{9}\) Therefore, viscosity differences are not enough to explain catalytic differences, for example the highest reactivity for Pd NPs immobilized in $\text{N00Cl-100}$ and $\text{N00Cl-100-3F03F}$, with respect to monoethers such as $\text{100}$. Thus, we observed that systems with a higher number of smaller NPs (mean diameter around 1–2 nm) presented enhanced reactivity, as in the case of $\text{Pd NPs/3F03F}$, due to a larger active surface. Conversely, systems with less-spherical and bigger NPs, dispersed in an inhomogeneous manner, such as $\text{ChCl-3F00}$ or $\text{N00Cl-3F00}$, would present less total active surface with respect to $\text{N00Cl-100}$, in agreement with a decrease in the TON. Besides, the formation of agglomerates notably reduces the catalytic active surface, which was probably the case of $\text{ChCl-000}$ and $\text{ChCl-3F00}$ solvents. Thus, Pd NPs morphology is modified by fine tuning of the solvent, triggering an effect on catalytic reactivity. For example, the size of NPs in $\text{N00Cl-100-3F03F}$ in between those of $\text{N00Cl-100}$ and $\text{N00Cl-3F00}$, resulted in an intermediate TON value (2740), with respect to those of $\text{N00Cl-100}$ (3920) and $\text{N00Cl-3F00}$ (1880). Furthermore, the observed catalytic behavior also indicates that the DES supramolecular structure impacts on the size of PdNPs (effect on the PdNPs formation mechanism) and dispersion (effect on stabilization), being $\text{N00Cl-100}$ the best solvent to lead to small PdNPs
and avoid their agglomeration, even after catalysis. Based on reported studies related to nanoparticles/solvent interactions, the electronic state of the PdNPs in the different solvents should be quite similar.\textsuperscript{50,51}

Furthermore, the solvent giving the best catalytic results, \textbf{N00Cl-100}, was used to perform additional recycling studies for the benchmark hydrogenation reaction (Scheme 4). With this aim, the recyclability of the system \textbf{Pd NPs/N00Cl-100}, compared to \textbf{Pd NPs/000} and \textbf{Pd NPs/100}, was evaluated. Results gathered in Figure 7 showed that, using 0.1 mol\% Pd, the deactivation of Pd NPs immobilized in glycerol (000) or in the monoether 100 started in the second cycle. In the case of using the system \textbf{Pd NPs/N00Cl-100}, quantitative conversions were achieved for three consecutive cycles. Notably, Pd NPs suspended in the eutectic medium displayed greater stability and recyclability than in the cases of the monoether or pure glycerol, even using a lower palladium load.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure7.png}
\caption{Conversions obtained after 30 minutes in the benchmark reaction catalyzed by Pd NPs immobilized in 000 (in yellow), 100 (in green) and N00Cl-100 (in blue), upon recovery using two Pd loads (0.1 mol\% –dashed– and 0.05 mol\% –solid–).}
\end{figure}
When using 0.05 mol% Pd (solid bars in Figure 7), the system Pd NPs/N00Cl-100 was reused in two reaction cycles with quantitative conversions and two additional runs with 61% of conversion. Unfortunately, cycles 5–7 showed a progressive deactivation of the catalytic system. Attempts to regenerate the catalyst, by hydrogen and thermal treatment, or by the addition of solvent, were not successful. TEM analysis of the reused Pd NPs immobilized in N00Cl-100 (Figure 8) showed no modifications in NPs size and morphology after two catalytic cycles. In addition, Pd NPs dispersion and size distribution diagrams were maintained. Above this, ICP-AES analyses of the crude extracts revealed the absence of palladium (< 0.05 ppm, detection limit for palladium). This information points to a surface reactivity mechanism. According to the Ostwald ripening, the leaching of atoms during the reaction and further redeposition on the surface of the NPs would progressively increase the NPs size, but this was not observed in our study. The additional stabilization of NPs by the solvent would reinforce the heterogeneous mechanism, as described for glycerol. However, from the fifth run onwards, some palladium agglomeration was visually observed. This issue is the possible reason for the progressive NPs deactivation.
Figure 8. TEM images and size distribution diagrams of Pd NPs/N00Cl-100 after catalyzing one and two runs the benchmark hydrogenation reaction (see Scheme 4).

Additionally, the solvent stability during the recycling was studied by $^1$H NMR analysis of the recovered N00Cl-100 after centrifugation of the catalytic phase, proving that no decomposition occurred (see Figure S23 in the ESI). The as-recovered catalyst was re-dispersed in fresh N00Cl-100 and used in the hydrogenation of (E)-4-phenylbut-3-en-2-one (1), exhibiting an important deactivation (<10% conversion). This behavior denotes a major effect of DES on the stabilization of Pd NPs during their synthesis.

The most active and recoverable catalytic system, Pd NPs/N00Cl-100, was successfully applied in the hydrogenation of different compounds (Tables 3 and 4).

Table 3. Hydrogenation scope catalyzed by Pd NPs/N00Cl-100.

| Entry a | Substrate | Product | Pd (mol%) | pH2 (bar) | Time (h) | Conv. b (%) | Selec. b (%) |

| 5       | ![4](image7) | ![4H](image8) | 1         | 3         | 4        | 80          | 56:44 c     |
Reaction conditions: The substrate (1 mmol) was dissolved in the colloidal solution of preformed Pd NPs in N00Cl-100 (1 mL, 1–10 mM Pd, 0.1–1 mol% Pd) in a Fisher-Porter vessel. Then, the vessel was placed under vacuum prior to its filling with H2 (1–20 bar), sealed and heated at 80 ºC. Reaction crudes were extracted using n-pentane. Conversion and selectivity were determined by 1H NMR using 1,4-dioxane as standard. 4H/internal alkenes ratio. 1H/1OH ratio.

The hydrogenation of conjugated alkenes, such as (E)-4-phenylbut-3-en-2-one (1), 2-vinynaphthalene (2) and 2,3,4,5-tetrahydro-1,1'-biphenyl (3), was quantitatively achieved using low Pd loadings and mild reaction conditions (Table 3, entries 1–3). In the case of non-conjugated linear alkenes such as 1-dodecene (4), the hydrogenation product 4H and different isomerization products were obtained at short reaction times (Table 3, entry 4). The complete hydrogenation of 4 towards n-dodecane (4H) was only achieved at longer reaction times (Table 3, entry 5), meaning that internal alkenes can also be successfully hydrogenated. However, this catalyst was not capable to complete the hydrogenation of a highly deactivated olefin such as 2H-chromen-2-one (5, entry 6). All these results point that the catalytic activity of Pd NPs/N00Cl-100 is at least comparable to other Pd NPs described in glycerol for similar substrates and reaction conditions. Additionally, this catalytic system required harsher reactions conditions in the reduction of ketones to the corresponding alcohols. Therefore, the hydrogenation of substrate 1 under 20 bar H2 pressure, afforded the total hydrogenation of the double bond as well as partial reduction of the carbonyl group (Table 3, entry 7).
**Pd-catalyzed semihydrogenation of alkynes**

The semihydrogenation of alkynes to alkenes, and in particular, phenyl acetylene to styrene, is a key enabling transformation for polymer industries as unwanted traces of alkynes in feedstock components act as poison for the polymerization catalysts used in polystyrene production plants.\(^{52}\) However, it is difficult to find the optimal catalyst and experimental conditions for carrying out this reaction avoiding the formation of the alkanes.\(^{39}\) We considered interesting to apply the system Pd NPs/N00Cl-100 to the semihydrogenation of different alkynes (Table 4).

**Table 4.** Hydrogenation of alkynes catalyzed by Pd NPs/N00Cl-100.

| Entry  | Substrate | pH\(_2\) (bar) | time (h) | Conv. \(^{b}\) (%) | Selectivity H/S \(^{b,c}\) |
|--------|-----------|----------------|----------|---------------------|--------------------------|
| 1      | 6         | 3              | 2        | 100                 | 99/1 (94)                |

| 8 \(^d\) | 8         | 1              | 0.5      | 16                  | 97/3 (14)                |
| 9 \(^d\) | 8         | 3              | 20       | 100                 | 0/100 (96)               |
| 10     | 9         | 1              | 0.5      | 0                   | 0/0 (0)                  |
| 11     | 9         | 1              | 2        | >99                 | 87/13 (87)               |
| 12     | 9         | 3              | 2        | 100                 | 0/100 (96)               |

\(^a\) Reaction conditions: The substrate (1 mmol) was dissolved in the colloidal solution of Pd NPs in N00Cl-100 solvent (1 mL, 1 mM Pd, 0.1 mol% Pd), prior to the vessel pressurization with H\(_2\) (1–3 bar) and heating at 80 °C. \(^b\) Conversion and selectivity were determined by \(^1\)H NMR using 1,4-dioxane as internal standard. \(^c\) Isolated yields given in brackets. \(^d\) 1 mol% Pd.
In order to find the optimal reaction conditions to carry out the semihydrogenation of substrates 6–9, different palladium loadings, hydrogen pressures and reaction times were assessed. In the case of 5-decyne (6), Pd NPs/N00Cl-100 provided its semihydrogenation with total conversion and selectivity towards (Z)-5-decene (6H, Table 4, entry 1), under mild conditions (0.1 mol% Pd, 3 bar H₂, 2 h). However, at longer reaction times full hydrogenation was observed (Table 4, entries 2-3). In the case of aryl alkynes such as phenyl acetylene (7) and 1-phenylpropyne (8), semihydrogenation towards 7H and 8H was not fully accomplished using this catalyst (Table 4, entries 4–6 and 8). Thus, these substrates were semihydrogenated with partial conversions (Table 4, entries 5 and 8). The best tested conditions in the hydrogenation reaction of diphenylacetylene (9) allowed to complete the conversion of the alkyne to an 87:13 9H/9S mixture (Table 4, entry 11). Therefore, the highest selectivity was achieved for internal alkyl alkynes.

In addition, the complete hydrogenation of the differently activated alkynes 6–9 was achieved by Pd NPs/N00Cl-100 (Table 4, entries 3, 7, 9 and 12) using palladium loadings lower than 1 mol% and mild reaction conditions (3 bar H₂, 80 °C).

Finally, the catalytic system Pd NPs/N00Cl-100 was also studied towards hydrodehalogenation reactions of haloarenes (see Scheme S1 in the ESI), exhibiting moderate to complete conversions, thus broadening the efficiency of this NPs system in hydrogen-mediated catalytic processes.

CONCLUSIONS

In this work, twenty-one green solvents such as glycerol and glyceryl monoethers, diethers and triethers, as well as the eutectic solvents resulting of their mixture with two bio-ammonium salts (ChCl and N00Cl), have been effectively used for the straightforward synthesis, immobilization and stabilization of palladium nanoparticles (Pd NPs). In the case of the DES, no additional stabilizers nor reductive agent are necessary for the reduction of the palladium precursor,
Pd(OAc)$_2$, thus improving the sustainability of Pd NPs preparation. The strong coordination of DES to Pd(0) have demonstrated the NPs stabilization role of the solvent. The morphology of Pd NPs strongly depended on the physicochemical properties of the used solvent, thus allowing to tune size, distribution and homogeneity of the NPs.

Palladium nanoparticles immobilized in glycerol-based solvents have shown high catalytic activity in the hydrogenation of conjugated and non-conjugated alkenes, alkynes and carbonyl compounds, as well as relevant selectivity in the semihydrogenation of alkynes to alkenes. Best results are obtained in pure glyceryl ethers and in N00Cl-R00 solvents, outstanding N00Cl-100. Finally, the physicochemical properties of glycerol-derived solvents as liquid supports for nanocatalysis play a key role in the activity outcomes and the recyclability of the catalytic systems.
