CONVERGENT NORMAL FORM AND CANONICAL CONNECTION FOR HYPERSURFACES OF FINITE TYPE IN $\mathbb{C}^2$

I. KOSSOVSKIY AND D. ZAITSEV

Abstract. We study the holomorphic equivalence problem for finite type hypersurfaces in $\mathbb{C}^2$. We discover a geometric condition, which is sufficient for the existence of a natural convergent normal form for a finite type hypersurface. We also provide an explicit construction of such a normal form. As an application, we construct a canonical connection for a large class of finite type hypersurfaces. To the best of our knowledge, this gives the first construction of an invariant connection for Levi-degenerate hypersurfaces in $\mathbb{C}^2$.

1. Introduction

In their celebrated paper [CM74], Chern and Moser constructed a convergent normal form for real-analytic hypersurfaces in $\mathbb{C}^N$, $N \geq 2$, at Levi-nondegenerate points. Since then, normal forms have attracted considerable attention, see e.g., Wong [Wo82], Ebenfelt [Eb98a, Eb98b], Kolar [Kol05], Kolar and Lamel [KL14], Moser and Webster [MW83], Gong [Go94, Go96], Huang and Yin [HY09], Coffman [Co06], Burcea [Bu13], Ezhov and Schmalz [ES96], and Beloshapka [Be94, Be02]. However, the problem of extending Chern-Moser’s result to Levi-degenerate points remains widely open.

Date: September 29, 2014.
In the previous paper [KZ14], the authors discovered a convergent normal form for real-analytic hypersurfaces in \( \mathbb{C}^N, N \geq 2 \), at so-called generic Levi degeneracy points (that is, points where the Levi form is of corank 1 and its determinant has nonvanishing differential along the Levi kernel). We refer the reader to the introduction given in that paper, for a general overview and discussion of normal forms and their importance. We recall that in the two-dimensional case, a formal normal form for finite type hypersurfaces in \( \mathbb{C}^2 \) was previously obtained by Kolar [Kol05]. Kolar also showed in [Kol12] that his normal form is divergent in general.

In this paper, we are looking for a more general than the one in [KZ14] optimal condition in \( \mathbb{C}^2 \) when a convergent normal form is possible. Here we consider normal forms of the kind

\[
v = \sum_{k,l>0} \Phi_{kl}(u) z^k \overline{z}^l, \quad (z, w) \in \mathbb{C} \times \mathbb{C}, \quad w = u + iv,
\]

given by conditions on the coefficient functions \( \Phi_{kl}(u) \). (This is motivated by the work of Chern-Moser [CM74] and the majority of known constructions in other cases.) In particular, this includes certain nondegeneracy condition imposed on the leading terms \( \sum \Phi_{kl} z^k \overline{z}^l \) with minimal \( k + l \). A convergent normal form of the latter kind is only possible when the type of the hypersurface is finite and constant along the line

\[
\Gamma = \{ z = 0, v = 0 \} = \{ (0, u) : u \in \mathbb{R} \}.
\]

This motivates the following definition.

**Definition 1.1.** Let \( M \subset \mathbb{C}^2 \) be a real-analytic hypersurface and \( p \in M \). We call a smooth real-analytic curve \( \gamma \subset \Sigma, \gamma \ni p \), a transverse curve of constant type, if \( \gamma \) is transverse to the complex tangent \( T_q^c M \) at any point \( q \in \gamma \) and the type of \( M \) is constant along \( \gamma \).

In view of the above discussion, the presence of such curve is a necessary condition for the existence of the kind of normal form under consideration. We prove here in Theorems 1 and 2 below that this condition is in fact sufficient.

Recall that the type of a hypersurface \( \Omega_{1.1} \) at 0 is the minimum \( k + l \) for which \( \Phi_{kl}(0) \neq 0 \). The type of a real hypersurface plays an important role, among others, in solving the \( \overline{\partial} \)-problem, see e.g. Kohn [Koh72], D’Angelo [DA82] and Catlin [Cat87].

Once a hypersurface contains a transverse curve of constant type, two fundamentally different cases occur, depending on whether the number of such curves is infinite or finite. These two cases can be invariantly distinguished by the set of points of maximum type:

**Definition 1.2.** Let \( M \subset \mathbb{C}^2 \) be a real-analytic hypersurface of finite type \( k \geq 3 \) at a point \( p \in M, U \) a sufficiently small neighborhood of \( p \) in \( \mathbb{C}^2 \), and \( \Sigma \ni p \) the Levi degeneracy set of \( M \). We call the (germ of the) set

\[
C = \left\{ q \in M \cap U : \text{the type of } M \text{ at } q \text{ equals } k \right\} \subset \Sigma
\]

the maximal type locus (or set) at \( p \).

Note that, according to the upper semi-continuity of the type in \( \mathbb{C}^2 \), in a sufficiently small neighborhood of a point \( p \in M \) of finite type \( k \geq 2 \) all other points in \( M \) have finite type, not exceeding \( k \).

It will be shown in Section 4 that the maximal type locus is either a single point, or a real-analytic subset of dimension 1 in \( M \), or a smooth real-analytic hypersurface in \( M \), which coincides with the whole Levi-degeneracy set \( \Sigma \). Due to the geometric nature, we have different normalization procedures in the 1- and 2-dimensional cases, as stated in Theorems 1 and 2 respectively.
1.1. **Convergent normal form.** We now formulate our first main result. We begin by recalling that a germ of a hypersurface of a finite type $k \geq 3$ can be always represented in suitable holomorphic coordinates as

$$v = P(z, \bar{z}) + o(|z|^k + |u|),$$

(1.3)

where $P(z, \bar{z})$ is a non-zero homogeneous polynomial of degree $k$ in $z, \bar{z}$ without harmonic terms. We expand (1.3) as

$$v = P(z, \bar{z}) + \sum_{\alpha, \beta \geq 0} \Phi_{\alpha\beta}(u) z^\alpha \bar{z}^\beta.$$

We then have $\Phi_{\alpha\beta}(0) = 0$ for $\alpha + \beta \leq k$.

**Theorem 1.** Let $M \subset \mathbb{C}^2$ be a real-analytic hypersurface of finite type $k \geq 3$ at a point $p \in M$. Assume that the maximal type locus at $p$ has dimension 2. Then there exists a biholomorphic map $F : (\mathbb{C}^2, p) \mapsto (\mathbb{C}^2, 0)$, which brings $(M, p)$ into a normal form

$$\left\{ v = P(z, \bar{z}) + \sum_{\alpha, \beta \geq k, \alpha, \beta > 0} \Phi_{\alpha\beta}(u) z^\alpha \bar{z}^\beta \right\},$$

where the polynomial $P(z, \bar{z}) = \frac{1}{k} \left((z + \bar{z})^k - z^k - \bar{z}^k\right)$, and $\Phi_{\alpha\beta}$ satisfy

$$\Phi_{\alpha 1} = 0, \alpha \geq k - 1, \quad \text{Re} \Phi_{k,k-1} = \text{Im} \Phi_{2k-2,2} = 0.$$  \hspace{1cm} (1.4)

The normalizing transformation $F$ is uniquely determined by the restriction of its differential $dF_p$ onto the complex tangent $T^C_p M$. Moreover, two germs $(M, p)$ and $(M^*, p^*)$ are biholomorphically equivalent if and only if, for some (and then for any) normal forms $(N, 0)$ and $(N^*, 0)$ of them, there exists a linear map

$$\Lambda(z, w) = (\lambda z, \lambda^k w), \lambda \in \mathbb{R} \setminus \{0\},$$

(1.5)

transforming $(N, 0)$ into $(N^*, 0)$. The Levi degeneracy set $\Sigma$ of $M$, which in this case is a smooth real-analytic totally real surface in $\mathbb{C}^2$, transverse to the complex tangent $T^C_p M$, is canonically foliated by distinguished biholomorphically invariant curves, called degenerate chains, where the chain through $p$ is locally given by $\{z = 0, v = 0\}$ in any normal form at $p$.

Theorem 1 addresses the case when the set of transverse curves of constant type through $p$ is infinite. Note that for $k = 3$ a finite type hypersurface in $\mathbb{C}^2$ has a generic Levi degeneracy, and thus automatically satisfies the conditions of Theorem 1. Convergence of a normal form in the latter case was already studied in [KZ14], however, for completeness we do not exclude it from our considerations.

On the other hand, Theorem 2 below addresses the case when the maximal type locus has dimension 1 and hence the set of transverse curves of constant type through $p$ is non-empty but finite. In the latter case, we call each such distinguished curve in $M$ again a degenerate chain, since it transforms into the line (1.2) in a suitable normal form. The finite collection $\{\gamma_1, ..., \gamma_s\}$ of degenerate chains in $M$ is an additional biholomorphic invariant of $M$, that is why the normalization procedure in this case is treated as a normalization of a triple $(M, \gamma_j, p)$ for some choice of an integer $j = 1, ..., s$.

**Theorem 2.** Let $M \subset \mathbb{C}^2$ be a real-analytic hypersurface of finite type $k \geq 3$ at a point $p \in M$. Assume that there exists at least one but finitely many transverse curves of constant type in $M$, passing through $p$. Then, for any choice of a transverse curve of constant type (degenerate chain)
through \( p \), there exists a biholomorphic map \( F: (\mathbb{C}^2, p) \rightarrow (\mathbb{C}^2, 0) \), sending \( \gamma \) into the line \((1.2)\) and \((M, p)\) into the normal form

\[
\left\{ v = P(z, \bar{z}) + \sum_{\alpha+\beta \geq k, \alpha, \beta > 0} \Phi_{\alpha\beta}(u) z^\alpha \bar{z}^\beta \right\},
\]

such that one of the two following cases (i) or (ii) holds:

(i) (circular case) The type \( k = 2\nu \) is even, \( P(z, \bar{z}) = |z|^k \), and the functions \( \Phi_{\alpha\beta} \) satisfy

\[
\Phi_{2\nu, 2\nu} = \Phi_{3\nu, 3\nu} = 0.
\]

The normalizing transformation \( F \) is uniquely determined by the restriction of its differential \( dF_p \) onto the complex tangent \( T_p^C M \) and the restriction of its Hessian \( D^2 F_p \) onto the tangent space \( T_p \gamma \). Moreover, two germs \((M, p)\) and \((M^*, p^*)\) are biholomorphically equivalent if and only if for some (and then for any) normal forms \((N, 0)\) and \((N^*, 0)\) of them there exists a linear-fractional map

\[
\Lambda(z, w) = \left( \frac{\lambda z^\nu \bar{z}^\nu}{1 + r w}, \frac{\lambda^{2\nu} w}{1 + r w} \right), \lambda, \theta, r \in \mathbb{R}, \lambda \neq 0,
\]

transforming \((N, 0)\) into \((N^*, 0)\). In turn, the degenerate chain \( \gamma \) at \( p \) is unique in this case.

(ii) (tubular/generic case) the polynomial \( P(z, \bar{z}) \) has the form

\[
P(z, \bar{z}) = z^\nu z^{k-\nu} + \bar{z}^\nu \bar{z}^{k-\nu} + \sum_{\nu+1 \leq j \leq k/2} (a_j z^j \bar{z}^{k-j} + \bar{a}_j \bar{z}^j z^{k-j})
\]

for some integer \( 1 \leq \nu < k/2 \), and the functions \( \Phi_{\alpha\beta} \) satisfy

\[
\Phi_{2\nu, 2\nu} = \Phi_{3\nu, 3\nu} = 0.
\]

The normalizing transformation \( F \) is uniquely determined by the restriction of its differential \( dF_p \) onto the complex tangent \( T_p^C M \). Moreover, two germs \((M, p)\) and \((M^*, p^*)\) are biholomorphically equivalent if and only if for some (and then for any) normal forms \((N, 0)\) and \((N^*, 0)\) of them there exists a linear map \((1.5)\), transforming \((N, 0)\) into \((N^*, 0)\).

Remark 1.3. We would like to emphasize that, in contrast with the Chern-Moser normal form, our normal form is invariant under the automorphism group of the associated polynomial model. In particular, given any \( M \) and \( M' \), any choice of normal forms can be used for their comparison.

Remark 1.4. It will be shown in the proof of Theorem 2 that the degenerate chain through \( p \) in the case (ii) is always unique, with the only exception of the so-called tubular case, when the polynomial \( P(z, \bar{z}) \) has the form

\[
P(z, \bar{z}) = \frac{1}{k} \left[ (z + \bar{z})^k - z^k - \bar{z}^k \right].
\]

On the other hand, as Example 5.1 in section 5 shows, the statement of Theorem 2 in the tubular case can not be strengthened: there exist hypersurfaces of this class, for which there are more than one (but finitely many) transverse curves of constant type, passing through a finite type point \( p \in M \).
We call the convergent normal form, provided by Theorems 1 and 2, the strong normal form. We note that this normal form is different from Kolar’s formal normal form in [Kol05] (see also Remark 2.2 below).

1.2. Canonical connection along the Levi degeneracy set. As our second main result, we construct a canonical connection on the Levi-degeneracy set in the case when the maximal type locus is 2-dimensional, which gives a different convergent normal form in that case and therefore a solution to the equivalence problem. We emphasize that this is a different kind of connection than the one known in the literature (e.g. [Car32, Ta62, CM74, Eb06, Mi89, GM97, IZ13, BES07, CS00, SS00, EIS99]). In contrast to situations considered in the cited work, where the connection arises due to certain “uniformity” of the CR-structure, in our case, already the rank of the Levi form is not constant. In this situation, known methods of constructing connections can not be used. Instead, we use a different, normal form inspired approach to construct a canonical connection only along the Levi degeneracy set. Since the latter is 2-dimensional, this connection turns out to be sufficient to solve the equivalence problem. As a byproduct, taking the normal coordinates of the complexified canonical connection, we obtain a new convergent normal form.

**Theorem 3.** Let \( M \subset \mathbb{C}^2 \) be a real-analytic hypersurface of finite type \( k \geq 3 \) at a point \( p \in M \). Suppose that the maximal type locus at \( p \) has dimension 2. Then the Levi degeneracy set \( \Sigma \) of \( M \) is a smooth real-analytic surface, transverse to \( T_p^\mathbb{C} M \) and totally real in \( \mathbb{C}^2 \). Moreover, one can define a canonical biholomorphically invariant connection \( \nabla \) on \( \Sigma \). The normal coordinates, given by the geodesic flow of the complexification of \( \nabla^\mathbb{C} \), reduce the CR-equivalence problem between two germs \((M, p)\) and \((M^*, p^*)\) as above to their linear equivalence problem in the normal coordinates. In fact, it suffices to consider linear scalings (1.5). Thus \( \nabla \) provides a solution for the biholomorphic equivalence problem for the above described class of real hypersurfaces.

An explicit construction of the connection \( \nabla \) is given in Section 6.

2. Modified formal normal form for finite type hypersurfaces

In this section we slightly modify Kolar’s formal normalization procedure and construct a similar to the one in [Kol05] but still different formal normal form for finite type hypersurfaces in \( \mathbb{C}^2 \). The main difference between the normal forms is that terms of as low as possible degree in \( z, \bar{z} \) are removed from the defining function in our case. This will be used later for the proof of convergence of the normal form.

2.1. Polynomial models for finite type hypersurfaces. Let \( M \subset \mathbb{C}^2 \) be a real-analytic hypersurface of finite type \( k \geq 3 \) at a point \( p \in M \). As well-known fact, one can choose local holomorphic coordinates \((z, w) = (z, u + iv)\) near \( p \) in such a way that \( p \) is the origin, \( T_p M = \{v = 0\} \), and the defining equation of \( M \) looks as

\[
v = P(z, \bar{z}) + O(k + 1).
\] (2.1)

Here \( P(z, \bar{z}) \) is a non-zero real-valued homogeneous polynomial in \( z, \bar{z} \) of degree \( k \) without harmonic terms, and \( O(k + 1) \) denotes the sum of weighted homogeneous polynomials in \( z, \bar{z}, u \) of
weight \( \geq k + 1 \), where the variables \( z, w \) are assigned the weights
\[
[z] = 1, \quad [w] = k.
\]
The real-algebraic hypersurface \( K = \{ v = P(z, \bar{z}) \} \) is called the polynomial model for \( M \) at \( p \). For the polynomial \( P(z, \bar{z}) \) we use expansion of the form
\[
P(z, \bar{z}) = \sum_{j=1}^{k-1} a_j z^j \bar{z}^{k-j}, \quad a_j \in \mathbb{C}, \quad a_j = a_{k-j}.
\]
As in Kolar [Kol05], in what follows we use the important

**Notation.** By \( \nu \) we denote the smallest integer \( 1 \leq j \leq k/2 \) such that \( a_j \neq 0 \).

We then can additionally normalize \( P(z, \bar{z}) \) by the condition \( a_\nu = 1 \) (by means of a scaling in \( z, w \)).

If now \( M = \{ v = \Phi(z, \bar{z}, u) \} \) and \( M^* = \{ v^* = \Phi^*(z^*, \bar{z}^*, u^*) \} \) are two hypersurfaces of finite type \( k \geq 3 \) at the origin, simplified as in (2.1) and having the same polynomial model \( K \), and
\[
z^* = f(z, w), \quad w^* = g(z, w)
\]
is a formal invertible transformation, transforming \( (M, 0) \) into \( (M^*, 0) \), we obtain the identity
\[
\text{Im } g(z, w)|_{w = u + i \Phi(z, \bar{z}, u)} = \Phi^*(f(z, w), \overline{f(z, w)}, \text{Re } g(z, w))|_{w = u + i \Phi(z, \bar{z}, u)}.
\]  
(2.2)

For the formal power series \( f(z, w) \in \mathbb{C}[[z, w]] \) we consider the formal expansion
\[
f(z, w) = \sum_{m \geq 1} f_m(z, w),
\]
where each \( f_m(z, w) \) is a weighted homogeneous polynomial of weight \( m \) (with respect to the above choice of weights), and similarly for \( g(z, w) \). For the defining function \( \Phi(z, \bar{z}, u) \) we use expansion of the form
\[
\Phi(z, \bar{z}, u) = P(z, \bar{z}) + \sum_{j,l \geq 0} \Phi_{jl}(u)z^j \bar{z}^l
\]
(note that each term in the latter sum has weight \( \geq k + 1 \)). We also denote for each \( m \geq 2 \)
\[
\Phi^{(m)}(z, \bar{z}, u) := \sum_{j+l=m} \Phi_{jl}(u)z^j \bar{z}^l.
\]

We then consider three cases, in each of which the normal form is significantly different.

**Tubular case.** In this case \( \nu = 1 \), and the polynomial \( P(z, \bar{z}) \) has the form
\[
P(z, \bar{z}) = \frac{1}{k} [(z + \bar{z})^k - z^k - \bar{z}^k].
\]
The polynomial model \( K \) in this case is polynomially equivalent to a tubular real hypersurface. In addition, \( K \) is invariant under the Lie group \( \{ \lambda \} \) of transformations, preserving the origin. An inspection of low weight terms in (2.2) (see [Kol05]) shows that the initial transformation \( F = (f, g) \) can be uniquely decomposed as \( F = \tilde{F} \circ \Lambda \), where \( \Lambda \) is as in (1.5) and the weighted components of the new mapping \( \tilde{F} \) satisfy
\[
f_1 = z, \quad g_1 = \cdots = g_{k-1} = 0, \quad g_k = w.
\]  
(2.3)

We now say that a formal hypersurface \( (M, 0) \) with a tubular polynomial model is in normal form, if its defining function \( \Phi(z, \bar{z}, u) \) satisfies
\[
\Phi_{\alpha 0} = 0, \quad \alpha \geq 0, \quad \Phi_{\alpha 1} = 0, \quad \alpha \geq k - 1, \quad \text{Re } \Phi_{k-2,1} = \text{Re } \Phi_{k,k-1} = \text{Im } \Phi_{2k-2,2} = 0.
\]  
(2.4)
Circular case. In this case $k$ is even, $\nu = k/2$, and the polynomial $P(z, \bar{z})$ has the form
\[ P(z, \bar{z}) = z^\nu \bar{z}^\nu. \]
The polynomial model $K$ in this case can be mapped into the quadric $Q = \{v = |z|^2\}$ by means of the polynomial map $z \mapsto z^\nu$, $w \mapsto w$, and hence is spherical at Levi nondegenerate points. It is also invariant under the Lie group (1.7) of transformations, preserving the origin. An inspection of low weight terms in (2.2) (see [Kol05]) shows that the initial transformation $F = (f, g)$ can be uniquely decomposed as $F = \tilde{F} \circ \Lambda$, where $\Lambda$ is as in (1.7) and the weighted components of the new mapping $\tilde{F}$ satisfy
\[ f_1 = z, \quad g_1 = \cdots = g_{k-1} = 0, \quad g_k = w, \quad \text{Re} \, g_{ww}(0,0) = 0. \quad (2.5) \]
We now say that a formal hypersurface $(\mathcal{M}, 0)$ with a circular polynomial model is in normal form, if its defining function $\Phi(z, \bar{z}, u)$ satisfies
\[ \Phi_{\alpha^0} = 0, \quad \alpha \geq 0, \quad \Phi_{\alpha^\nu} = 0, \quad \alpha \geq \nu, \quad \Phi_{\nu, \nu-1} = \Phi_{2\nu, 2\nu} = \Phi_{3\nu, 3\nu} = 0. \quad (2.6) \]

Generic case. In this case the polynomial model $K$ is neither tubular nor circular, and we call it (following Kolar [Kol05]) generic in what follows. In the same way as in the tubular case, $K$ is invariant under the Lie group (1.5) of transformations, preserving the origin, and an inspection of low weight terms in (2.2) shows that the initial transformation $F = (f, g)$ can be uniquely decomposed as $F = \tilde{F} \circ \Lambda$, where $\Lambda$ is as in (1.5) and the weighted components of the new mapping $\tilde{F}$ satisfy (2.3). To describe the normal form in the generic case, we need to introduce (see also [Kol05]) a natural Hermitian form on each space $\mathbb{H}_m$ of homogeneous (but not necessarily real-valued) polynomials in $z, \bar{z}$ of degree $m \geq 2$. Namely, if $Q = \sum_{j=0}^m a_j z^j \bar{z}^{m-j} \in \mathbb{H}_m$, $R = \sum_{j=0}^m b_j z^j \bar{z}^{m-j} \in \mathbb{H}_m$, $a_j, b_j \in \mathbb{C}$, we define
\[ (Q, R) := \sum_{j=1}^{m-1} a_j \bar{b}_j. \quad (2.7) \]
This Hermitian form (2.7) is degenerate, however, it is nondegenerate on the subspace
\[ \mathcal{L}_k \subset \mathcal{H}_k \]
consisting of polynomials without harmonic terms (thus (2.7) is a scalar product on each $\mathcal{L}_k$). We now say that a formal hypersurface $(\mathcal{M}, 0)$ with a generic polynomial model is in normal form, if its defining function $\Phi(z, \bar{z}, u)$ satisfies
\[ \Phi_{\alpha^0} = 0, \quad \alpha \geq 0, \quad \Phi_{\alpha^\nu} = 0, \quad \alpha \geq k - \nu, \quad \text{Im} \, \Phi_{2k-2\nu, 2\nu} = 0, \quad (\Phi^{(k-1)}, P_z) = 0. \quad (2.8) \]

2.2. Modified Kolar's normal form. We now formulate our formal normalization result on the modified Kolar’s normal form.

**Proposition 2.1.** Let $\mathcal{M} \subset \mathbb{C}^2$ be a real-analytic hypersurface of finite type $k \geq 3$ at a point $p$, simplified as above, and $K = \{v = P(z, \bar{z})\}$ its polynomial model at $p$.

(i) Let the polynomial model $K$ be of tubular type. Then for any choice of a non-zero real parameter $\lambda$ there exists a unique formal invertible transformation $F = (f, g)$, bringing $(\mathcal{M}, 0)$ into a normal form (2.4) and satisfying $f_z(0,0) = \lambda$. 

**Proposition 2.1.** Let $\mathcal{M} \subset \mathbb{C}^2$ be a real-analytic hypersurface of finite type $k \geq 3$ at a point $p$, simplified as above, and $K = \{v = P(z, \bar{z})\}$ its polynomial model at $p$.

(i) Let the polynomial model $K$ be of tubular type. Then for any choice of a non-zero real parameter $\lambda$ there exists a unique formal invertible transformation $F = (f, g)$, bringing $(\mathcal{M}, 0)$ into a normal form (2.4) and satisfying $f_z(0,0) = \lambda$. 

(ii) Let the polynomial model $K$ be of circular type. Then for any choice of a non-zero real parameter $\lambda$ and real parameters $\theta, \rho$ there exists a unique formal invertible transformation $F = (f, g)$, bringing $(M, 0)$ into a normal form \((2.6)\) and satisfying $f_z(0, 0) = \lambda e^{i\theta}$, $\Re g_{uu}(0, 0) = \rho$.

(iii) Let the polynomial model $K$ be of generic type. Then for any choice of a non-zero real parameter $\lambda$ there exists a unique formal invertible transformation $F = (f, g)$, bringing $(M, 0)$ into a normal form \((2.8)\) and satisfying $f_z(0, 0) = \lambda$.

Remark 2.2. We emphasize that this normal form is merely formal to begin with. It does coincide with the normal form in Theorem 1, implying its convergence in that case. However, it does not, in general, coincide with the normal form in Theorem 2. The reason being that, in general, this formal normal form may not transfer the distinguished degenerate chain $\gamma$ into the line \((1.2)\). Instead, in Theorem 2 we construct another convergent normal form trasfering the degenerate chain into the line \((1.2)\) and having fewer conditions on the defining equation of the hypersurface.

The strategy of the proof of Proposition 2.1 is similar to that used in Kolar [Kol05]. As follows from the discussion above, it is sufficient to prove the claim of Proposition 2.1 for the case of a map $F$, satisfying \((2.3)\) in the tubular and generic cases, and \((2.5)\) in the circular case, so that we assume $F$ to be normalized accordingly. We also use for the defining function $\Phi$ of $M$ expansion of the form

$$\Phi(z, \bar{z}, u) = P(z, \bar{z}) + \sum_{m \geq k+1} \Phi_m(z, \bar{z}, u),$$

where each $\Phi_m(z, \bar{z}, u)$ is a weighted homogeneous polynomial of weight $m$. We then consider \((2.2)\) as an infinite series of weighted homogeneous equations, which can be written for any fixed weight $m \geq k + 1$ as

$$\Re (ig_m + P_z f_{m-k+1}) \big|_{w = u + iP(z, \bar{z})} = \Phi^*_m - \Phi_m + \cdots, \quad (2.9)$$

where dots stands for a polynomial in $z, \bar{z}, u$ and $f_j, g_j$ with $j < m$ and their derivatives in $u$ (here $f_{j-k+1} = f_{j-k+1}(z, u)$, $g_j = g_j(z, u)$, $\Phi_j = \Phi_j(z, \bar{z}, u)$).

Let us denote by $\mathcal{F}$ the space of formal real-valued power series $\Phi(z, \bar{z}, u) = \sum_{m \geq k+1} \Phi_m(z, \bar{z}, u)$, and by $\mathcal{N} \subset \mathcal{F}$ the subspace of formal series, satisfying one of the normalization conditions \((2.4)\), \((2.6)\) or \((2.8)\), depending on the polynomial model under consideration. Denote also by $\mathcal{G}$ the spaces of pairs $(f, g)$ of formal power series without constant term, satisfying \((2.3)\) or \((2.5)\), also depending on the polynomial model under consideration. In view of \((2.9)\), in order to prove Proposition 2.1, it is sufficient to prove the following proposition.

**Proposition 2.3.** Let $M$ be a real-analytic hypersurface of finite type $k \geq 3$ at a point $p$, simplified as above, $K = \{v = P(z, \bar{z})\}$ its polynomial model at $p$, and $L$ denotes the linear operator

$$L(f, g) := \Re (ig + P_z f) \big|_{w = u + iP(z, \bar{z})}.$$

Then, in either of the tubular, circular or generic cases, for the linear operator $L(f, g)$ we have the direct sum decomposition $\mathcal{F} = L(\mathcal{G}) \oplus \mathcal{N}$.

Indeed, it follows from Proposition 2.3 in each of the cases that if $m \geq k + 1$ is an integer and all $f_{j-2}, g_j, \Phi^*_j$ with $j < m$ are already determined, then one can uniquely choose the collection $(f_{m-2}, g_m, \Phi^*_m)$ in such a way that \((2.9)\) is satisfied and $\Phi^*_m \in \mathcal{N}$. This implies the existence and uniqueness of the desired normalized mapping $(f, g)$ and the normalized right-hand side $\Phi^*(z, \bar{z}, u)$. 
**Proof of Proposition 2.3.** The statement of the proposition is equivalent to the fact that an equation

\[ L(f, g) = \Psi(z, \bar{z}, u), \quad (f, g) \in \mathcal{G} \]  

(2.10)

in \((f, g)\) has a unique solution, modulo \(\mathcal{N}\) in the right-hand side, for any fixed \(\Psi \in \mathcal{F}\). To simplify the calculations, we rescale \((2.10)\) as

\[ 2L(f, g) = \Psi(z, \bar{z}, u), \quad (f, g) \in \mathcal{G}, \quad \Psi \in \mathcal{F}, \]  

(2.11)

which we solve in \(f, g\). We use expansions of the form

\[ f(z, u + iP(z, \bar{z})) = f(z, u) + f_u(z, u)iP + \frac{1}{2}f_{uu}(z, u)i^2P^2 + \cdots. \]

Substituting into \((2.11)\) we get the equation

\[ i\left( g(z, u) + g_u(z, u)iP + \frac{1}{2}g_{uu}(z, u)i^2P^2 + \cdots \right) + \]

\[ + P_z \left( f(z, u) + f_u(z, u)iP + \frac{1}{2}f_{uu}(z, u)i^2P^2 + \cdots \right) + \]

\[ + \{ \text{complex conjugate terms} \} = \Psi(z, \bar{z}, u). \]  

(2.12)

For the sequel of the proof, we expand \(f(z, w)\) as \(f = \sum_{k \geq 0} f_k(w)z^k\), and similarly for \(g\). We then address each of the three cases separately.

**Tubular case.** Collecting in \((2.12)\) terms of bi-degrees \((\alpha, 0)\), \(\alpha \geq 0\) in \(z, \bar{z}\), we get

\[ ig(z, u) - ig_0(u) + z^{k-1}\bar{f}_0(u) = \sum_{\alpha \geq 0} \Psi_{\alpha 0}(u)z^\alpha. \]  

(2.13)

The equation \((2.13)\) enables us to determine uniquely the functions \(g_\alpha(u), \alpha \neq 0, k - 1\), as well as the function \(\text{Im} g_0(u)\), in such a way that the conditions \(\Psi_{\alpha 0} = 0, \alpha \neq k - 1\) are achieved. In addition, we have

\[ ig_{k-1} + \bar{f}_0 = \Psi_{k-1,0}. \]

(2.14)

Gathering then terms of bi-degrees \((\alpha, 1)\) with \(\alpha \geq 1\), we get

\[ -g_u z^{k-1} - g'_0 z^{k-1} + (k - 1)z^{k-2}f + z^{k-1}\bar{f}_1 + (k - 1)z^{k-2}\bar{f}_0 - iz^{2k-2}\bar{f}_0 = \sum_{\alpha \geq 1} \Psi_{\alpha 1}(u)z^\alpha. \]  

(2.15)

The equation \((2.15)\) enables us to determine uniquely all \(f_\alpha, \alpha \neq 0, 1, k\), as well as \(\text{Re} f_0\), in order to achieve the conditions \(\Psi_{\alpha 1} = 0, \alpha \geq k, \alpha \neq 2k - 2\) and \(\text{Re} \Psi_{k-2,1} = 0\). Thus we uniquely determine from \((2.14)\) \(\text{Im} g_{k-1}\) and achieve \(\text{Re} \Psi_{k-1,0} = 0\). In addition, we have the conditions

\[ -2\text{Re} g'_0 + (k - 1)f_1 + \bar{f}_1 = \Psi_{k-1,1} \]

(2.16)

and

\[ -g'_{k-1} + (k - 1)f_k - i\bar{f}_k = \Psi_{2k-2,1}. \]  

(2.17)

By considering the imaginary part in \((2.17)\) we uniquely determine \(\text{Im} f_k\) and achieve the condition \(\text{Im} \Psi_{2k-1,1} = 0\).

In what follows we use the notation

\[ \{ \text{pdt} \} \]

for a linear differential expression, depending on previously determined terms. Considering then in \((2.12)\) terms of bi-degree \((2k - 2, 2)\), we obtain

\[ \{ \text{pdt} \} + i(k - 1)f'_1 - i\bar{f}'_1 = \Psi_{2k-2,2}. \]  

(2.18)
Recall that, in view of \(2.3\), \(f'_1(0) = g'_0(0) = 1\). Hence the imaginary part of the equation \(2.18\), read together with the equation \(2.16\), enables us to determine \(\text{Re } g_0, f_1\) uniquely and achieve the conditions \(\Psi_{k-1,1} = \text{Im } \Psi_{2k-2,2} = 0\). Finally, we consider in \(2.12\) terms of bi-degree \((k,k-1)\), we obtain

\[-g'_{k-1} + f_k - icf_0^2 = \Psi_{k,k-1},\]  \hspace{1cm} (2.19)

where \(c = c(k)\) is a positive integer. Then, by considering the imaginary part in \(2.14\) and the real parts in \(2.17\) and \(2.19\), we get a \(3 \times 3\) real linear system for \(\text{Im } f'_0, \text{Re } g'_{k-1}, \text{Re } f_k\), which is nondegenerate for any positive \(c\) and \(k \geq 3\). Thus we determine \(\text{Im } f_0, \text{Re } g_{k-1}, \text{Re } f_k\) uniquely (thanks to \(f_0(0) = 0\)) and achieve \(\text{Im } \Psi_{k-1,0} = \text{Re } \Psi_{2k-2,1} = \Psi_{k,k-1} = 0\).

All the terms, concerned in the normalization conditions \(2.4\), have been considered, and this proves the proposition in the tubular case.

**Circular case.** Collecting in \(2.12\) terms of bi-degrees \((\alpha,0), \alpha \geq 0\) in \(z, \bar{z}\), we get

\[ig(z,u) - ig_0(u) = \sum_{\alpha \geq 0} \Psi_{\alpha 0}(u) z^\alpha.\]  \hspace{1cm} (2.20)

The equation \(2.20\) enables us to determine uniquely the functions \(g_\alpha(u), \alpha > 0\), as well as the function \(\text{Im } g_0(u)\), in such a way that the conditions \(\Psi_{\alpha 0} = 0\), \(\alpha \geq 0\) are achieved.

Gathering then terms of bi-degrees \((\alpha,\nu)\) with \(\alpha \geq 1\), we get

\[-g_\alpha z^\nu - g'_0 z^\nu + z^{\nu-1}f + \nu z^\nu \tilde{f}_1 = \sum_{\alpha \geq 1} \Psi_{\alpha\nu}(u) z^\alpha.\]  \hspace{1cm} (2.21)

The equation \(2.21\) enables us to determine uniquely all \(f_\alpha, \alpha \neq 1\), in order to achieve the conditions \(\Psi_{\alpha\nu} = 0, \alpha \geq \nu + 1\), and \(\Psi_{\nu\nu-1} = 0\) (recall that we have \(\nu = k - \nu\) in the circular case). In addition, we have the condition

\[\nu \text{Re } f_1 - \text{Re } g'_0 = \Psi_{\nu\nu}.\]  \hspace{1cm} (2.22)

Considering then in \(2.12\) terms of bi-degrees \((2\nu,2\nu)\) and \((3\nu,3\nu)\), we get, respectively,

\[\text{Im } g'_0 - 2\nu\text{Im } f'_1 = \Psi_{2\nu,2\nu}\]  \hspace{1cm} (2.23)

and

\[\frac{1}{3}\text{Re } g''_0 - \nu\text{Re } f''_1 = \Psi_{3\nu,3\nu}.\]  \hspace{1cm} (2.24)

Recall that, thanks to \(2.5\), we have \(g_0(0) = g'_0(0) = \text{Im } f'_1(0) = \text{Re } g'_0(0) = 0\) and \(\text{Re } f'_1(0) = 1\). Hence we determine \(\text{Im } f_1\) uniquely from \(2.23\) and achieve \(\Psi_{2\nu,2\nu} = 0\), and also determine \(\text{Re } f_1, \text{Re } g_0\) uniquely from \(2.22\), \(2.21\) and achieve \(\Psi_{\nu\nu} = \Psi_{3\nu,3\nu} = 0\).

All the terms, concerned in the normalization conditions \(2.6\), have been considered, and this proves the proposition in the circular case.

**Generic case.** Collecting in \(2.12\) terms of bi-degrees \((\alpha,0), \alpha \geq 0, \alpha \neq k - 1\) in \(z, \bar{z}\), we get

\[ig(z,u) - ig_0(u) = \sum_{\alpha \neq k-1} \Psi_{\alpha 0}(u) z^\alpha.\]  \hspace{1cm} (2.25)

The equation \(2.25\) enables us to determine uniquely the functions \(g_\alpha(u), \alpha \neq 0; k - 1\) as well as the function \(\text{Im } g_0(u)\), in such a way that the conditions \(\Psi_{\alpha 0} = 0, \alpha \neq k - 1\) are achieved.

Let us introduce the unique polynomial \(Q \in \mathcal{L}_k\) (\(\mathcal{L}_k\) being the space of polynomials without harmonic terms as before), which coincides with \(P_z\) modulo harmonic terms. We have \(Q, \bar{Q} \in \mathcal{L}_k\).
We then consider in (2.12) all terms of bi-degrees $z^\alpha \bar{z}^\beta$, $\alpha + \beta = k - 1$, and apply to both sides the multiplication by $Q$ with respect to the Hermitian form (2.7). We get:

$$f_0(Q, Q) + \bar{f}_0(Q, Q) = (\Psi^{(k-1)}, Q).$$

(2.26)

Since $(\cdot, \cdot)$ is nondegenerate on $L_k$, by the Cauchy inequality we have

$$|(Q, Q)| \leq \sqrt{(Q, Q)} \cdot \sqrt{(|\bar{Q}, Q|)} = (Q, Q),$$

and the equality achieved if and only if $Q$ is a scalar multiple of $\bar{Q}$. It is easy to see that in the latter case the polynomial model $K = \{v = P(z, \bar{z})\}$ is tubular, which is a contradiction. Thus $(Q, Q) > |(Q, Q)|$, and the equation (2.26) enables us to determine $f_0$ uniquely and achieve the condition $(\Phi^{(k-1)}, P_2) = 0$. Now, by considering in (2.12) terms of bi-degree $(k - 1, 0)$, we obtain

$$i g_{k-1} + \{\text{pdt}\} = \Psi_{k-1,0},$$

and we determine from here $g_{k-1}$ uniquely and achieve the condition $\Psi_{k-1,0} = 0$.

Gathering then terms of bi-degrees $(\alpha, \nu)$ with $\alpha \geq k - \nu$, we get

$$-2\text{Re} \ g_0' \cdot z^{k-\nu} + (k - \nu)z^{k-\nu-1}(f - f_0) + \nu z^{k-\nu}\bar{f}_1 + \{\text{pdt}\} = \sum_{\alpha \geq k-\nu} \Psi_{\alpha\nu}(u) z^\alpha.$$  \hspace{1cm} (2.27)

The equation (2.27) enables us to determine uniquely all $f_\alpha$, $\alpha > 1$, and achieve the conditions $\Psi_{\alpha\nu} = 0$, $\alpha > k - \nu$. In addition, we have the condition

$$-2\text{Re} \ g_0' + (k - \nu)f_1 + \nu \bar{f}_1 = \Psi_{k-\nu,\nu}.$$  \hspace{1cm} (2.28)

Note that, since the polynomial model $K$ is not circular, we have $\nu < k/2$, so that we determine $\text{Im} \ f_1$ uniquely by considering the imaginary part of the equation (2.28) and achieve $\text{Im} \ \Psi_{k-\nu,\nu} = 0$. Finally, we consider in (2.12) terms of bi-degree $(2k - 2\nu, 2\nu)$, we obtain

$$\{\text{pdt}\} + i(k - \nu)f_1 - i\nu f_1 = \Psi_{2k-2\nu,2\nu}. \hspace{1cm} (2.29)$$

Recall that, in view of (2.3), $f_1'(0) = g_0'(0) = 1$. Hence the imaginary part of the equation (2.29), read together with the equation (2.28), enables us to determine $\text{Re} \ g_0, f_1$ uniquely and achieve the conditions $\Psi_{k-\nu,\nu} = \text{Im} \ \Psi_{2k-2\nu,2\nu} = 0$.

All the terms, concerned in the normalization conditions (2.6), have been considered, and this completes the proof of the proposition.  \hspace{1cm} \Box

**Corollary 2.4.** Suppose that $(N, 0)$ and $(\tilde{N}, 0)$ are two different formal normal forms of a fixed germ $(M, p)$ of a real-analytic hypersurface of finite type $k \geq 3$ at the point $p$. Suppose, in addition, that the polynomial model for $M$ at $p$ is either tubular or generic. Then there exists a linear transformation $\Lambda$, as in (1.5), which maps $(N, 0)$ into $(\tilde{N}, 0)$.

**3. Special normal form for hypersurfaces of finite type**

We now aim to construct a complete normal form under the action of a special subgroup of the group $\text{Aut}(\mathbb{C}^2, 0)$ of formal biholomorphisms of $(\mathbb{C}^2, 0)$. Namely, we consider the subgroup

$$\{ F = (f, g) \in \widehat{\text{Aut}}(\mathbb{C}^2, 0) : f(0, w) = 0, \text{ Im} \ g(0, u) = 0 \}. \hspace{1cm} (3.1)$$

This subgroup has a natural geometric interpretation as the subgroup of all formal biholomorphisms, preserving the distinguished curve (1.2). Thus, a normalization procedure under the
action of the group (3.1) for real-analytic hypersurfaces, already containing the curve (1.2), can be interpreted as a normalization of a triple

\[(M, \gamma, p), \quad p \in \gamma \subset M,\]

where \(M\) is a real-analytic hypersurface of finite type \(k\) at the distinguished point \(p\), and \(\gamma \subset M\) is a distinguished curve through \(p\), transverse to the complex tangent \(T^C_p M\).

We now describe the special normal form in each of the cases. Note that if a hypersurface \(M \ni 0\) contains the curve (1.2), then its defining function satisfies \(\Phi_{00}(u) = 0\).

First, if a (formal) hypersurface \(M\) is of tubular type, we say that \(M\) is in a special normal form, if its defining function satisfies

\[\Phi_{\alpha_0} = 0, \quad \alpha \geq 0, \quad \Phi_{\alpha_1} = 0, \quad \alpha \geq k, \quad \text{Im} \Phi_{2k-2,2} = 0.\]  

(3.2)

Next, if a (formal) hypersurface \(M\) is of circular type, we say that \(M\) is in a special normal form, if its defining function satisfies

\[\Phi_{\alpha_0} = 0, \quad \alpha \geq 0, \quad \Phi_{\alpha_2} = 0, \quad \alpha \geq \nu, \quad \Phi_{2\nu,2\nu} = \Phi_{3\nu,3\nu} = 0, \quad \nu = k/2.\]  

(3.3)

Finally, if a (formal) hypersurface \(M\) is of generic type, we say that \(M\) is in a special normal form, if its defining function satisfies

\[\Phi_{\alpha_0} = 0, \quad \alpha \geq 0, \quad \Phi_{\alpha_2} = 0, \quad \alpha \geq k - \nu, \quad \text{Im} \Phi_{2k-2\nu,2\nu} = 0,\]  

(3.4)

where \(\nu\) is as in Theorem 2. We now formulate our special normalization statement.

**Proposition 3.1.** Let \(M\) be a real-analytic hypersurface of finite type \(k \geq 3\) at a point \(p\), simplified as in (2.1) and containing the curve (1.2), and \(K\) its polynomial model at \(p\).

(i) Let the polynomial model \(K\) be of tubular type. Then for any choice of a non-zero real parameter \(\lambda\) there exists a unique formal invertible transformation \(F\), as in (3.1), bringing \((M, 0)\) into a special normal form (3.2) and satisfying \(f_z(0, 0) = \lambda\).

(ii) Let the polynomial model \(K\) be of circular type. Then for any choice of a non-zero real parameter \(\lambda\) and real parameters \(\theta, \rho\) there exists a unique formal invertible transformation \(F = (f, g)\), as in (3.1), bringing \((M, 0)\) into a special normal form (3.3) and satisfying \(f_z(0, 0) = \lambda e^{i\theta}\), \(\text{Re} g_{w\bar{w}}(0, 0) = \rho\).

(iii) Let the polynomial model \(K\) be of generic type. Then for any choice of a non-zero real parameter \(\lambda\) there exists a unique formal invertible transformation \(F = (f, g)\), as in (3.1), bringing \((M, 0)\) into a special normal form (3.4) and satisfying \(f_z(0, 0) = \lambda\).

**Proof.** The proof is completely analogous to the one in Section 2.2, and we leave the details to the reader. The only difference is that in the proof of the direct decomposition

\[\mathcal{F} = L(G_1) \oplus \mathcal{N}, \quad L(f, g) = \text{Re} \left((ig + P_z f) \big|_{w=u+iP(z,\bar{z})}\right),\]

one should assume, in the notations of the proof of Proposition 2.3,

\[\text{Im} g_0(u) = 0, \quad f_0(u) = 0.\]

Because of these constraints, less terms can be finally eliminated in the defining function \(\Phi\) of \(M\), that is why the special normal form appears to be simpler than the one in Section 2 or the one in [Kol05].
Corollary 3.2. Suppose that \((N, 0)\) and \((\tilde{N}, 0)\) are two different special normal forms of a fixed triple \((M, \gamma, p)\), when \(M\) is a real-analytic hypersurface of finite type \(k \geq 3\) at the point \(p\) and \(\gamma \subset M\), \(\gamma \ni p\) is a curve, transverse to the complex tangent \(T^C_p M\). Suppose, in addition, that the polynomial model for \(M\) at \(p\) is either tubular or generic. Then there exists a linear transformation \(\Lambda\), as in \((1.5)\), which maps \((N, 0)\) into \((\tilde{N}, 0)\).

4. Transverse curves of constant type and degenerate chains

4.1. Structure of the maximal type locus. Let \(M \subset \mathbb{C}^2\) be a real-analytic hypersurface of finite type \(k \geq 3\) at a point \(p \in M\). Recall that the subset of points in a neighborhood of \(p\) in \(M\), at which the type equals \(k\), is called the maximal type locus at \(p\). Before proceeding with the proof of Theorems 1 and 2, we need the following two structure results for the maximal type locus of a finite type hypersurface.

Proposition 4.1. Let \(M \subset \mathbb{C}^2\) be a real-analytic hypersurface of finite type \(k \geq 3\) at a point \(p \in M\). Then the following alternative holds.

(I) Either the maximal type locus at \(p\) is a single point,

or

(II) the maximal type locus at \(p\) is a real-analytic subset of \(M\) of dimension 1,

or

(III) the maximal type locus is a smooth real-analytic hypersurface in \(M\), which coincides with the whole Levi degeneracy set \(\Sigma\).

Proof. Let \(\Delta(q)\) denotes the Levi form of \(M\) (which can be considered as a scalar function on \(M\) in the case of \(\mathbb{C}^2\)), and \(\Sigma\) the Levi degeneracy set of \(M\). We have

\[
\Sigma = \{q \in M : \Delta(q) = 0\}.
\]

Note that, as follows from \((2.1)\), the type of \(M\) at a point \(q\) equals \(l \geq 3\) if and only if

\[
\Delta(q) = d\Delta(q)|_{T^C_q} = \ldots = d^{k-3}\Delta(q)|_{T^C_q} = 0, \quad \text{while} \quad d^{k-2}\Delta(q)|_{T^C_q} \neq 0.
\]

Thus the maximal type locus \(C \subset \Sigma\) is contained in the real-analytic set

\[
E = \{q \in \Sigma : \Delta(q) = d\Delta(q)|_{T^C_q} = \ldots = d^{k-3}\Delta(q)|_{T^C_q} = 0\},
\]

describing the set of points in \(M\) of type \(\geq k\). However, since the type \(k\) is locally maximal for points in \(M\) near \(p\), we have \(C = E\) (locally near \(p\)). If \(E\) has dimension 0 or 1, then the assertion in (I) or (II), respectively, holds. Otherwise \(E = C\) has dimension 2, and the same holds for \(\Sigma\). Since, in addition, \(d^{k-2}\Delta(p)|_{T^C_q} \neq 0\), we conclude (after intersecting \(M\) with a sufficiently small neighborhood \(U\) of \(p\), if necessary) that \(C\) is smooth at \(p\). To prove that \(C = \Sigma\), we notice that if \(\tilde{C} \neq C\) is another component of the real-analytic set \(\Sigma\), passing through \(p\) (which has dimension 1 or 2), then we can find a point \(q \in C\) near \(p\), which is not contained in any other component of \(\Sigma\) rather than \(C\). Clearly, the characterizing property \((4.1)\) can not hold at \(p\) and \(q\) simultaneously with the same \(l\), in view of the existence of an additional component in \(\tilde{C} \subset \Sigma\), while both \(p\) and \(q\) lie in the maximal type locus \(C\), which is a contradiction. This proves the assertion in (III). \(\Box\)

From here we can deduce
Proposition 4.2. Let $M \subset \mathbb{C}^2$ be a real-analytic hypersurface of finite type $k \geq 3$ at a point $p \in M$, and assume that $M$ contains a transverse curve of constant type through $p$. Then the following alternative holds.

(I) Either the Levi degeneracy set $\Sigma$ contains only finitely many transverse curves of constant type, passing through $p$,

or

(II) the Levi degeneracy set $\Sigma \subset M$ contains infinitely many transverse curves of constant type, passing through $p$, and in this case the maximal type locus at $p$ coincides with the whole Levi degeneracy set $\Sigma$, while the latter is a smooth real-analytic hypersurface in $M$, transverse to the complex tangent $T_p^C M$ and totally real in $\mathbb{C}^2$. Moreover, the polynomial model for $M$ in the latter case is tubular at any point $q \in \Sigma$.

Proof. After applying Proposition 3.1, it remains to prove that in case (II) the polynomial model for $M$ is tubular at any point $q \in \Sigma$. Without loss of generality we may assume $q = p$. We choose local holomorphic coordinates near $p$ in such a way that $p$ is the origin, $T_0 M = \{v = 0\}$, and the totally real manifold $\Sigma$ is given by $\{\text{Re } z = 0, v = 0\}$. If we denote the polynomial model for $M$ at $p$ by $P(z, \bar{z})$, then the Levi form of $M$ near $p$ looks as

$$\Delta(z, \bar{z}, u) = P_{z\bar{z}} + O(|u|) + O(|z|^{k-1}) \quad (4.3)$$

Since the set $\Sigma$ coincides with the maximal type locus $C$, given by (4.2), the right hand side in (4.3) vanishes identically for $\text{Re } z = 0$, so that $P_{z\bar{z}}$ vanishes identically for $\text{Re } z = 0$. Similarly, all the derivatives $P_{z^i\bar{z}^j}$, $i, j \geq 1$, $i + j \leq k - 1$ vanish identically for $\text{Re } z = 0$, while at least one of the derivatives $P_{z^i\bar{z}^j}$, $i, j \geq 1$, $i + j = k$ is non-zero at the origin. This proves that, up to harmonic terms, $P(z, \bar{z}) = \lambda (\text{Re } z)^k$, $\lambda \neq 0$, as required.

\[\square\]

In accordance with Proposition 3.2, for a real-analytic hypersurface $M \subset \mathbb{C}^2$ of finite type $k \geq 3$ at the point $0 \in M$, simplified as in (2.1), we consider four cases, in each of which the convergent normalization procedure is significantly different.

**Case G.** In this case the tangent model $K$ at $0$ is generic, and there exist finitely many transverse curves of constant type through $0$ (all of which are contained in a real-analytic set of dimension 1).

**Case C.** In this case the tangent model $K$ at $0$ is circular, and there exist finitely many transverse curves of constant type through $0$ (all of which are contained in a real-analytic set of dimension 1).

**Case T1.** In this case the tangent model $K$ at $0$ is tubular, and there exist finitely many transverse curves of constant type through $0$ (all of which are contained in a real-analytic set of dimension 1).

**Case T2.** In this case the tangent model $K$ at $0$ is tubular, and there exist infinitely many transverse curves of constant type through $0$; the Levi degeneracy set $\Sigma \subset M$ coincides with the maximal type locus $C$ at $p$ and is a totally real surface in $\mathbb{C}^2$, transverse to the complex tangent $T_p^C M$. Note that, as follows from Proposition 3.2, $M$ is of class T2 at any other point $p \in C$ in this case.
4.2. Degenerate chains. We next introduce in each of the cases distinguished transverse curves of constant type, passing through 0 and lying in the Levi degeneracy set \( \Sigma \) of \( M \). We call them \textit{degenerate chains}.

If \( M \) is of one of the classes G, C or T1, we simply call each of the transverse curves of constant type, passing though 0, a \textit{degenerate chain}. We have at most finitely many degenerate chains, passing through 0 in these cases.

If, otherwise, \( M \) is of class T2, the construction of degenerate chains is more involved. We first introduce a canonical pair of foliations in the Levi degeneracy set \( \Sigma \). Both ones are defined by the use of appropriate slope (line) fields in the smooth real-analytic manifold \( \Sigma \), which we integrate then.

To define the first slope field, we choose a point \( p \in \Sigma \) and coordinates \((z,w)\) vanishing at \( p \), where \( M \) takes the form (2.1). Clearly, these coordinates can be chosen polynomial with coefficients depending analytically on \( p \). Let \( N \) denotes a (formal) normal form (2.4) of \( M \) at \( p \), \( F \) a formal transformation, mapping \((M,p)\) onto \((N,0)\), and \( e := (0,1) \in \mathbb{C}^2 \). We then define a slope at \( p \) as follows:

\[
l(p) := \text{span}_\mathbb{R} \{ (dF|_p)^{-1}(e) \} \subset T_p \Sigma.
\]

We have to prove the inclusion \( l(p) \subset T_p \Sigma \) and the fact that \( l(p) \) is analytic in \( p \). First, it follows from Corollary 2.4 that the definition of \( l \) is independent of the choice of normal form. Moreover, the desired slope can be also defined without using formal transformations. Indeed, it follows from the normal form construction that, as soon as the initial weighted polynomials \( \{ \Phi_j^*, f_{j-k+1}, g_j, k+1 \leq j \leq m \} \) for some \( m \geq k+1 \) have been determined, they do not change after further normalization of terms of higher weight. Hence, solving the equations (2.9) for \( m \) sufficiently large (namely, for all \( m \leq 2k-1 \)), we uniquely determine \( dF|_p \). Note that, if a hypersurface of class T2 satisfies (2.1), then the tangent space to its Levi degeneracy set at the origin is given by \( \{ \text{Re} z = 0, v = 0 \} \). Hence the latter tangent space for a hypersurface, normalized up to weight \( 2k - 1 \), contains the vector \( e \), and it follows from the invariance of \( \Sigma \) that \( l(p) \subset T_p \Sigma \). It is also not difficult to see from here that the constructed slope field is analytic (i.e., depends analytically on a point \( p \in \Sigma \)). Indeed, the explicit construction in the beginning of Section 2 shows that each fixed weighted polynomial \( \Phi_m \), depends on \( p \) analytically (this can be verified from the parameter version of the implicit function theorem). Hence polynomials \( f_m \) and \( g_m \) depends on \( p \) analytically, as it is obtained by solving a system of linear equations with a fixed nondegenerate matrix in the left-hand side and right-hand side analytic in \( p \) (the latter fact can be seen from the proof of Proposition 2.3). We immediately conclude that \( dF|_p \) depends on \( p \) analytically, and so does \( l(p) \). We then integrate the analytic slope field \( l(p) \) and obtain a canonical (non-singular) real-analytic foliation \( T \) of the Levi degeneracy set \( \Sigma \). We call each of the leaves of the foliation \( T \) a \textit{degenerate chain}. Each degenerate chain \( \gamma \subset \Sigma \) at each point \( p \in \gamma \) is transverse to the complex tangent \( T_p^CM \).

The second canonical foliation in \( \Sigma \) corresponds to the slope field

\[
c(p) := T_p^CM \cap T_p \Sigma.
\]

Integrating \( c(p) \) we obtain another canonical foliation \( S \) in \( \Sigma \), which is everywhere tangent to \( T^CM \). Both foliations \( T \) and \( S \) are transverse to each other and are biholomorphic invariants of \((M,0)\). We call them respectively \textit{transverse} and \textit{tangent} foliations.

Degenerate chains play a crucial role in the convergent normalization procedure, described in the next section.
5. Convergent normalization to the strong normal form

5.1. Construction of the normalizing transformation. We proceed now with the proof of the existence of a normalizing transformation in Theorems 1 and 2. As before, $M \subset \mathbb{C}^2$ denotes a real-analytic hypersurface of finite type $k \geq 3$ at the point $0 \in M$. We assume $(M,0)$ to be simplified, as in (2.1). In each of the cases the normalizing transformation, satisfying (2.3) (cases G,T1 and T2) or (2.5) (case C) and bringing $(M,0)$ into one of the normal forms (1.6),(1.4),(1.8), is a finite composition of biholomorphic transformation, each of which is a normalization of certain geometric data, associated with a finite type hypersurface. We describe below the transformations and their geometric meaning. For the set-up of the theory of Segre varieties see, e.g., [BER99]. The first few steps are the same for all of the four cases, while the final steps are significantly different for each case.

Normalization of a chain. We choose any chain $\gamma \subset \Sigma$, passing through 0, and perform a biholomorphic transformation, transferring $\gamma$ into the curve $\Gamma = \{z = 0, v = 0\}$. Since such a transformation has the form $z^* = z + O(|w|), w^* = w + O(|w|^2)$, it preserves the form (2.1). Now the new hypersurface $M$ satisfies (2.1), contains $\Gamma$ and has the constant type $k$ at each point $q \in \Gamma$.

Normalization of Segre varieties along a chain. The next step in the normalization procedure is the elimination of $(\alpha,0)$ terms in the expansion of $\Phi$, which is sometimes addressed as transfer to normal coordinates (see [BER99]). Geometrically, this step can be interpreted as straightening of the Segre varieties $Q_p, p \in \Gamma$. According to [CM74], [BER99], we perform the unique transformation of the form

$$z^* = z, \quad w^* = w + g(z,w), \quad g(0,w) = 0,$$

which maps $M$ into a hypersurface with $\Phi^*_{\alpha 0} = 0, \alpha \geq 0$. This transformation preserves the curve $\Gamma$ and the form (2.1). Segre varieties of points $p = (0,\eta) \in \Gamma$ look all now as $\{w = \eta\}$, accordingly, for any $p \in \Gamma$ we now have $T^C_p M = \{w = 0\}$.

Presence of the transverse curve $\Gamma \subset \Sigma$ of constant type and the fact that all the complex tangents along $\Gamma$ have the form $\{w = 0\}$ imply strong consequences for the defining function $\Phi$ of $M$. Applying the property (4.2) for any point $q = (0,\eta) \in \Gamma$, we obtain, in view of $T^C_q M = \{w = 0\}$,

$$\Phi_{z^\alpha \bar{z}^\beta}(z,\bar{z},u)|_{z=\bar{z}=0} \equiv 0, \quad \alpha, \beta \geq 0, \quad \alpha + \beta \leq k - 1.$$

This immediately implies that $M$ satisfies, after the transformation (5.1), the conditions

$$\Phi^*_{\alpha 0} = 0, \alpha \geq 0, \quad \Phi^*_{\alpha \beta} = 0, \alpha, \beta \geq 0, \alpha + \beta \leq k - 1.$$

Normalization of the Segre map. This step can be interpreted as a normalization of the Segre map of $M$ near 0. Our goal is to bring a hypersurface, obtained in the previous step, to such a form that it satisfies, in addition, the condition

$$\Phi^*_{\alpha \nu} = 0, \alpha \geq k - \nu.$$

The Segre map of $M$ assigns to each point $p$ in a neighborhood of the origin in $\mathbb{C}^2$ a (fixed) sufficiently high jet of its Segre variety $Q_p$ at the point with $z = 0$. In this step we aim to
normalize the first and the \((\nu + 1)\)-th components of the Segre map as

\[
p = (\xi, \eta) \mapsto (\eta, *, \cdots, 2i\xi^{k-\nu}, *)).
\] (5.3)

We provide the construction of the desired transformation only for the case C (circular case), as in all other cases the proof is very similar. Thus we assume \(P(z, \bar{z}) = z^\nu \bar{z}^\nu\). We first achieve the condition \(\Phi_{k-\nu, \nu} = \Phi_{\nu, \nu} = 0\). Choose a real-valued analytic function \(\lambda(u)\) such that \(\lambda(0) = 1\) and \(1 + \Phi_{\nu, \nu}(u) = \lambda^{2\nu}(u)\) (recall that \(\Phi_{\nu, \nu}(0) = 0\)). We perform the biholomorphic change

\[
z^* = z\lambda(w), \ w^* = w.
\]

Using expansions of the form \(h(u + iv) = h(u) + ih'(u)v + \ldots\), we conclude that \(\Phi^*\) also satisfies (5.2) and, since

\[
\Phi(z, \bar{z}, u) = \Phi^*(z^*, \bar{z}^*, u^*) \text{ for } (z, w) \in M,
\]

we get

\[
1 + \Phi_{\nu, \nu}(u) = (1 + \Phi^*_{\nu, \nu}(u))\lambda^{2\nu}(u),
\]

so that \(M\) is mapped into a hypersurface satisfying \(\Phi^*_{\nu, \nu} = 0\), as required.

Second, for the hypersurface \(M^*\), obtained after a transformation \(F_2\). We aim to remove the \((k - \nu + 1)\)-terms from \(M\) by means of this transformation. Clearly, \(M^*\) satisfies (5.2) and also \(\Phi^*_{\nu, \nu}(u) = 0\). Then, using (5.4) and the fact that all terms in \(\Phi(z, \bar{z}, u)\) have uniform degree \(\geq k\) in \(z, \bar{z}\), it is not difficult to compute that

\[
\Phi_{k-\nu, \nu}^*(u^*) = (k - \nu)f_2(u^*) + \Phi_{k-\nu+1, \nu}(u^*).
\]

The latter identity determines the holomorphic near the origin function \(f_2\) uniquely. Proceeding with similar arguments, we uniquely determine holomorphic functions \(f_3, \ldots, f_{\nu}\) such that the composition \(F_{\nu} \circ \cdots \circ F_2\) maps \(M\) into a hypersurfaces satisfying

\[
\Phi^*_{\alpha, \beta} = 0, \ \alpha \geq 0, \ \Phi^*_{\alpha, \beta} = 0, \ \alpha, \beta \geq 0, \ \alpha + \beta \leq k - 1, \ \Phi^*_{\alpha, \nu} = 0, \ k - \nu \leq \alpha \leq k - 1. \quad (5.5)
\]

Finally, for a hypersurface, satisfying (5.5), we perform a transformation

\[
\begin{aligned}
z = z^* + f(z^*, w^*), & \quad w = w^*, \quad f(z^*, w^*) = O(|z^*|^\nu + 1)
\end{aligned}
\]
in order to remove the \((\alpha, \nu)\)-terms with \(\alpha \geq k\). Clearly, the target hypersurface \(M^*\) satisfies (5.5). Let us put \(f = z^*h\), \(h = O(|z^*|^\nu)\). Using (5.5) and (5.4), we compute

\[
\sum_{\alpha \geq k} \Phi^*_{\alpha, \nu}(u^*)(z^*)^\alpha(z^*)^\nu = \sum_{\alpha \geq k} \Phi_{\alpha, \nu}(u^*)(z^*)^\alpha(z^*)^\nu + (z^*)^{k-\nu}(z^*)^\nu (1 + h)^{k-\nu - 1}.
\]

Deviding the latter identity by \((z^*)^{k-\nu}(z^*)^\nu\), we obtain a suitable \(h\) with \(h = O(|z^*|^\nu)\) by the implicit function theorem. It is straightforward that the Segre map is now given by (5.3).

We end up with a hypersurface satisfying

\[
\Phi^*_{\alpha, \beta} = 0, \ \alpha \geq 0, \ \Phi^*_{\alpha, \beta} = 0, \ \alpha, \beta \geq 0, \ \alpha + \beta \leq k - 1, \ \Phi^*_{\alpha, \nu} = 0, \ \alpha \geq k - \nu. \quad (5.6)
\]

The remaining part of the normalization procedure is significantly different in each of the cases G, C, T1, T2, that is why we address each of them separately.

**Cases G and T1.**
Fixing a parameterization on a degenerate chain. Since $M$ already satisfies (5.6), it remains to achieve the last normalization condition in (1.8), namely, the condition $\text{Im} \Phi_{2k-2\nu,2\nu} = 0$. We do so by means of a gauge transformation

$$z \mapsto zf(w), \quad w \mapsto g(w), \quad f(0) \neq 0, \quad g(0) = 0, \quad g'(0) \neq 0.$$  \hfill (5.7)

This transformation can be interpreted as a choice of a parameterization on the degenerate chain $\Gamma$. We choose

$$f(w) := (g'(w))^{1/k}, \quad g(w) \in \mathbb{R}\{w\}, \quad g(0) = 0, \quad g'(0) = 1.$$  

It is easy to see that (5.6) is preserved under such transformation. Let us denote by $S$ the space of convergent series $\Psi(z, \bar{z}, u)$, satisfying (1.8). Then, using again expansions of kind $h(u + iv) = h(u) + ih'(u)v + \ldots$, we compute

$$v^* = g'(u)v \mod S,$$

$$(z^*)^\nu (\bar{z}^*)^{k-\nu} = z^\nu \bar{z}^{k-\nu}g'(u) \left(1 + \frac{g''(u)}{g'(u)}\right)^{\nu/k} \left(1 - ig''(u)\right)^{(k-\nu)/k} \mod S =$$

$$= g'(u)z^\nu \bar{z}^{k-\nu} + i \frac{2\nu - k}{k} g''(u)z^{2\nu} \bar{z}^{2k-2\nu} \mod S.$$  

Similarly, for $\nu < \alpha < k/2$ we get (recall that $\nu < k/2$):

$$(z^*)^\alpha (\bar{z}^*)^{k-\alpha} = g'(u)z^\alpha \bar{z}^{k-\alpha} \mod S,$$

thus

$$v^* - P(z^*, \bar{z}^*) = g'(u)(v - P(z, \bar{z})) + i \frac{2\nu - k}{k} g''(u)(z^{2\nu} \bar{z}^{2k-2\nu} - z^{2\nu} \bar{z}^{2k-2\nu}) \mod S.$$  

We conclude that

$$\text{Im} \Phi^*_v = g' \text{Im} \Phi_{2k-2\nu,2\nu} + \frac{2\nu - k}{k} g'',$$

so that the condition $\text{Im} \Phi_{2k-2\nu,2\nu} = 0$ leads to a second order nonsingular ODE. Solving it with the initial condition $g'(0) = 1$, we finally obtain a hypersurface of the (1.8). It is not difficult to see, performing similar calculations, that the gauge transformation chosen to achieve $\text{Im} \Phi_{2k-2\nu,2\nu} = 0$ must have the above form $z^* = z(g'(w))^{1/k}$, $w^* = g(w)$ and hence is unique up to the choice of the real parameter $g'(0)$, corresponding to the action of the group (1.5).

Note finally, that we have already brought $M$ to a special normal form (3.4) or (3.2), respectively, corresponding to the triple $(M, \gamma, p)$ for the chosen chain $\gamma$. Thus, remarkably,

we can canonically, up to the action of the group of dilations (1.3), choose a parameterization on each degenerate chain.

**Case C.** In the circular case, since $M$ already satisfies (5.6), it remains to achieve the normalization conditions $\Phi_{2\nu,2\nu} = \Phi_{3\nu,3\nu} = 0$ in (1.6). We do so again by means of gauge transformations.

Fixing a unit vector along a degenerate chain. In this step we aim to achieve the condition $\Phi_{2\nu,2\nu} = 0$. For that we perform a transformation (5.7) with

$$f(w) = e^{i\text{h}(w)}, \quad g(w) = w, \quad h(w) \in \mathbb{R}\{w\}, \quad h(0) = 0.$$  \hfill (5.8)

Note that, as follows from (5.2), the monomial $z^\nu \bar{z}^{\nu'}$ is apparent at any point $p \in \Gamma$, sufficiently close to 0. Hence (after, possibly, shrinking $\Gamma$) to any point $p \in \Gamma$ we can assign a canonical nondegenerate polylinear form

$$\varphi : (T_p^C M)^\nu \times \overline{(T_p^C M)^\nu} \to \mathbb{C} \otimes (T_p M/T_p^C M),$$
given by \( k \)-th order brackets (as can be seem, for example, from (2.1)). Thus the transformation (5.8) can be interpreted as a choice of a unit vector with respect to the canonical polylinear form \( \varphi \), at each point \( p \in \Gamma \) (i.e., for any \( p \in \Gamma \) we fix a vector \( e_p \in T_p M : \varphi(e_p, \ldots, e_p, e_p, \ldots, e_p) = 1 \)).

By arguments similar to the ones used above, we conclude that \( M^* \) satisfies (5.6), and compute:

\[
\Phi^*_{2\nu,2\nu}(u) = \Phi_{2\nu,2\nu}(u) - 2\nu h'(u).
\]

Thus the requirement \( \Phi^*_{2\nu,2\nu}(u) = 0 \) leads to a first order nonsingular ODE, that we solve uniquely with the initial condition \( h(0) = 0 \).

**Fixing a parameterization on a degenerate chain.** Similarly to case \( G \), we perform a transformation (5.7) with

\[
f(w) := (g'(w))^{1/k}, \quad g(w) \in \mathbb{R}\{w\}, \quad g(0) = g''(0) = 0, \quad g'(0) = 1,
\]

which corresponds to a canonical choice of a parameterization on a degenerate chain. Let us introduce the space \( S_c \) of convergent series \( \Psi(z, \bar{z}, u) \), satisfying (1.6). We compute

\[
v^* = g'(u)v - \frac{1}{6} v^3 \mod S_c,
\]

\[
(z^*)''(z^*)'' = g'(u)z''z''' + \frac{1}{2} \left( \frac{(g'')^2}{g'} - g'''' \right) \mod S_c,
\]

\[
v^* - (z^*)''(z^*)'' = g'(u)(v - z''z''') + \left( \frac{1}{3} g''' - \frac{(g'')^2}{2g'} \right) z''^2 z'''' \mod S_c.
\]

Thus

\[
\Phi^*_{3\nu,3\nu} = g'\Phi_{3\nu,3\nu} + \frac{1}{3} g''' - \frac{(g'')^2}{2g'},
\]

and the requirement \( \Phi^*_{3\nu,3\nu} = 0 \) leads to a third order nonsingular ODE, which we solve uniquely with the initial conditions \( g(0) = 0, \ g'(0) = 1, \ g''(0) = 0 \). It is not difficult to see, performing similar calculations, that the gauge transformation chosen to achieve \( \Phi^*_{3\nu,3\nu} = 0 \) must have the above form \( z^* = z(g'(w))^{1/k}, \ w^* = g(w) \) and hence is unique up to the choice of the real parameters \( g'(0), \ g''(0), \ g'''(0) \neq 0 \), corresponding to the subgroup in (1.7) normalized by \( \theta = 0 \). Thus, similarly to the \( G \) and \( T1 \) cases, we can canonically, up to the action of the group of the real projective group

\[
t \mapsto \frac{at}{1 + bt}, \quad a, b \in \mathbb{R}, \ a \neq 0,
\]

choose a parameter \( t \) on each degenerate chain.

**Case T2.** We claim that for a hypersurface of class \( T2 \), satisfying (5.6), we have \( \Re \Phi_{k,k-1}(u) = 0 \) in (5.6). Indeed, consider the (formal) transformation \( F = (f, g) \), bringing a hypersurface (5.6) into normal form (2.4), and study the equation (2.22), applied to it. We use notations from the proof of Proposition 2.3. Collecting terms with \( z^n z^0 u^0, \alpha \geq 0 \), we first obtain the condition \( g(z, 0) = 0 \), which we use in what follows. Next, gathering terms with \( z^{k-2} z^1 u^1 \), we obtain \( \Re f'_0(0) = 0 \). Finally, gathering terms with \( z^{k-1} z^0 u^1, z^{2k-2} z^1 u^0, z^k z^{k-1} u^0 \), it is straightforward to check that we obtain, respectively, the equation (2.11), differentiated and evaluated at 0 with \( \Psi_{k-1}(0) := 0 \), the equation (2.17), evaluated at 0 with \( \Psi_{k-2,1}(0) := 0 \), and the equation (2.19), evaluated at 0 with \( \Psi_{k,k-1}(0) := 2\Phi_{k,k-1}(0) \) (this follows from the partial normalization (5.6) of \( M \), the normalization conditions (2.3) for the target \( M^* \), and the identity \( g(z, 0) = 0 \)). Moreover, \( \Im f'_0(0) = 0 \) thanks to the fact that \( \Gamma \) is a degenerate chain. We immediately conclude from the above obtained equations that \( g'_{k-1}(0) = f_k(0) = 0 \) and \( \Re \Phi_{k,k-1}(0) = 0 \). Since the prenormal
form (5.6) is invariant under the real shifts \( w \mapsto w + u_0, u_0 \in \mathbb{R} \), and \( \Gamma \subset M \) is a degenerate chain, we similarly conclude that \( \Re \Phi_{k,k-1}(u_0) = 0 \) for any small \( u_0 \in \mathbb{R} \) in (5.6), as required. Thus we have achieved all the normalization conditions in (2.4), except \( \Im \Phi_{2k-2,2}(u) = 0 \). The step in the normalization procedure, aiming to achieve the normalization condition \( \Im \Phi_{2k-2,2}(u) = 0 \), can be addressed as a choice of a parameterization on the unique degenerate chain, passing through 0, and is completely analogous to the similar step in the cases G and T1, so that we leave the details to the reader. In particular, in view of the fact that \( M \) is already in the normal form (2.4), we can canonically, up to the action of the group of dilations (1.5), choose a parameterization on each degenerate chain.

5.2. Uniqueness properties for a normalizing transformation. For the proof of the uniqueness statements in Theorems 1 and 2 we address each of the cases G, C, T1, T2 separately.

Case G. Since a hypersurface of kind G, satisfying (1.8), is also in the normal form (2.8), the only statement that needs to be proved in this case is the fact that there exists a unique degenerate chain, passing through \( p \). As follows from the proof in Section 5.1, a degenerate chain is given by the equation (1.2) in any normal form (1.8) of it. Now the desired uniqueness follows from Corollary 2.3 and the fact that any transformation (1.5) preserves the curve (1.2).

Case C. We again notice that any hypersurface of kind C, which is in a a strong normal form (1.6), is also in the normal form (2.6). This implies the required uniqueness statement for the normalizing transformation.

Next, we show that any transformation (1.7) preserves the strong normal form (2.6). As the statement is obvious for a transformation, belonging to the subgroup in (1.7) normalized by \( r = 0 \), it is sufficient to prove it for the subgroup in (1.7), normalized by \( \lambda = 1, \theta = 0 \). Each such transformation \( F \) satisfies all the conditions in (5.9), except \( g''(0) = 0 \) (we have \( g''(0) = -2r \)). Then, performing a calculation, identical to (5.10), we get that the fact that the new hypersurface \( M^* \) satisfies (1.6) amounts to the third order nonsingular ODE

\[
\frac{1}{3} g''' - \frac{(g'')^2}{2g'} = 0. 
\]  

(5.11)

It is easy to check that the function \( g(w) := \frac{w}{1+aw} \) satisfies (5.11), so that \( M^* \) is in the strong normal form (1.6), as required. It is straightforward now that any two strong normal forms of a fixed germ of kind C are related by means of a transformation (1.7).

The proof of the uniqueness of the degenerate chain, passing through \( p \), is identical to the proof of a similar fact in case G (as any transformation (1.7) preserves the curve (1.2)).

Case T1. In this case we shall use the special normal form, considered in Section 3. Let \( M \) be a hypersurface of class T1, which is brought into a strong normal form (1.8) after a certain choice of a degenerate chain \( \gamma \) through \( p \), as described in the proof in Section 4.1. Then \( M \) is also in the special normal form (3.2), associated with the triple \((M, \gamma, p)\). Now the uniqueness statement for a strong normalization map \( F \) follows from Proposition 3.1.

If, for some choice of degenerate chains \( \gamma_1 \supset p_1, \gamma_2 \supset p_2 \), two germs \((M_1, p_1)\), \((M_2, p_2)\) of class T1 have the same strong normal form, then they are obviously biholomorphically equivalent. On the other hand, if two germs \((M_1, p_1)\), \((M_2, p_2)\) of class T1 are biholomorphically equivalent by means of a mapping \( H : (M_1, p_1) \to (M_2, p_2) \), we fix a degenerate chain \( \gamma_1 \subset M_1 \) through \( p_1 \) and \( \gamma_1 \) is mapped into a degenerate chain \( \gamma_2 \subset M_2 \) through \( p_2 \). Thus \( H \) performs a biholomorphic equivalence between the triples \((M_1, \gamma_1, p_1)\) and \((M_2, \gamma_2, p_2)\) (in the sense of the considerations in

we can canonically, up to the action of the group of dilations (1.5), choose a parametrization on each degenerate chain.
Section 3), and by Corollary 3.2 some special normal forms of them are mapped onto each other by means of a transformation (1.5), as required.

**Case T2.** As any hypersurface of kind T2, satisfying (1.4), is also in the normal form (2.4), the proof of all desired facts immediately follows from the formal normalization Proposition 2.1 and the proof in Section 5.1.

Theorems 1 and 2 are completely proved now. The following example shows, that the discrete parameter $\sigma$, corresponding to a choice of a degenerate chain in $M$ through $p$ in the case T1, can actually occur.

**Example 5.1.** Consider the real-analytic hypersurface $M \subset C^2$ of type 4 at the origin with a tubular polynomial model, given by the equation

$$v = (\text{Re } z)^3 (\text{Re } z + (\text{Im } z)^2 - u^2).$$

It is easy to check that at all points, belonging to either of the curves

$$\gamma_{\pm} = \{\text{Re } z = 0, \text{Im } z = \pm u, v = 0\},$$

the hypersurface $M$ has type 4, while at points with $z = 0, v = 0, u \neq 0$ the type of $M$ equals 3. Hence the Levi degeneracy set $\Sigma$ has dimension 2, and $M$ is of class T1 at 0 (as follows from Propositions 3.1 and 3.2). At the same time, $M$ contains at least two transverse curves of constant type through 0.

6. **Canonical connection for hypersurfaces of class T2**

In this section we apply the strong normal form to construct a canonical connection on the Levi degeneracy set of a hypersurface of class T2, such that the restriction of its complexification onto the initial hypersurface $M$ gives a solution for the holomorphic equivalence problem for germs at Levi degenerate points of hypersurfaces of class T2. Recall that the Levi degeneracy set $\Sigma$ in the case T2 is a totally real surface $\Sigma \subset C^2$, and one can define the transverse and the tangent foliations $T$ and $S$ on $\Sigma$, respectively. Both $T$ and $S$ are biholomorphically invariant and transverse to each other.

Let $q \in \Sigma$ be a point in a neighborhood of the reference point $p$, and $X,Y$ denotes a pair of smooth vector fields on $\Sigma$ near $q$. We denote the leaves of the foliations $T$ and $S$ through $p$ by $t_p$ and $s_p$, respectively. We can assume (by fixing a tangent vector $e_p \in T_{p}t_p$) that all the chains $t_q$ are parameterized (see Section 5). In order to define a connection $\nabla_X(X)$ on $\Sigma$, it is sufficient to define, for any $q \in \Sigma$ and each pair $X,Y$, a parallel translation of $X_q$ along the integral curve of $Y$ through $q$. Since $T$ and $S$ are transverse to each other, it is sufficient, by linearity, to define the parallel translation in the cases when (i) $X_q \in T_qt_q, Y_q \in T_qs_q$; (ii) $X_q \in T qs_q, Y_q \in Tqt_q$; (iii) $X_q \in T qt_q, Y_q \in T qs_q$; (iv) $X_q \in Tqs_q, Y_q \in Tqt_q$. In other word, we define a parallel translation for a vector, tangent to either of the leaves $t_q, s_q$, along either of the leaves $t_q, s_q$.

In case (i), we translate $X_q$ to a point $r \in s_p$ as follows. We consider the leaf $t_r$, and consider the analytic diffeomorphism $h$ of $(t_q, q)$ onto $(t_r, r)$, which assigns to each $\zeta \in t_q$ the intersection point $s_\zeta \cap t_q := \{\zeta'\}$. Then the desired vector $Z$, parallel to $X_q$, is defined as $Z := dh|_{q}(X_q)$.

Case (ii) is completely analogous to (i).

In case (iii), we use the existence of a parameterization $t_q = \{\gamma_q(\xi)\}$, $\gamma_q(\xi_1) = q, \gamma_q(\xi_2) = r$ on the chain $t_q$ to simply translate the vector $\gamma'_{q}(t_1)$ into the vector $\gamma'_{q}(t_2)$, for any $r \in t_q$, and then by linearity extend the procedure for all other $X_p \in Tqt_q$. Clearly, this definition is independent of the choice of the vector $e_p$. 
Finally, in case (iv) we note that a hypersurface of finite type \( k \geq 3 \) with a tubular polynomial model at a point \( q \in M \) admits a canonical nondegenerate \( k \)-form

\[
\varphi_q : (T^\mathbb{C}_qM)^{k-1} \times \overline{T^\mathbb{C}_qM} \mapsto \mathbb{C} \otimes (T_qM/T^\mathbb{C}_qM),
\]
given by \( k \)-th order brackets (as can be seen from (2.4)). Since \( M \) has the same polynomial model at each point \( q \in \Sigma \) (see Section 3), we get a canonical nondegenerate \( k \)-form \( \varphi \) on \( \Sigma \). Considering its restrictions on the tangent spaces \( T_qs_q \), we obtain a canonical nondegenerate \( k \)-form \( \psi \), which we may interpret as a one valued in \( T_qt_q \) for each \( q \in \Sigma \):

\[
\psi_q : (T_qs_q)^{k-1} \times T^\mathbb{C}_qT_qs_q \mapsto T_qt_q.
\]

Now the desired parallel translation in case (iv) is performed as follows. Fixing a point \( r \in s_q \), we take the vector \( W := \psi(X_q, \ldots, X_q, X_q) \), translate in parallelly along the leaf \( s_p \) as described in case (i), and obtain the resulting vector \( V \in T_\tau t_\tau \). Now the desired vector \( Z \in T_\tau s_\tau \) is uniquely defined by the condition \( \psi(Z, \ldots, Z, \overline{Z}) = V \).

Thus we obtain a unique canonical connection \( \nabla \), invariant under biholomorphic transformations of a germ \((M, p)\). As follows from the construction, all the chains \( t_q \), as well as the tangent leaves \( s_q \), are geodesics for this connection. We may consider now the exponential mapping (geodesic flow)

\[
\exp(X) : (\mathbb{R}^2, 0) \mapsto (\Sigma, p)
\]

for the connection \( \nabla \), and the map \( \exp^{-1} \) gives canonical (normal) coordinates \((x_1, x_2)\) for \( \Sigma \). If \((M, p)\) was initially simplified in such a way that

\[
T_p t_p = \{ z = 0, v = 0 \}, \quad T_p s_p = \{ w = 0, \text{Re } z = 0 \},
\]
then in the normal coordinates \( p \) is the origin, the transverse leaves \( t_q \) all look as \( \{ x_1 = \text{const} \} \), and the tangent leaves \( s_q \) as \( \{ x_2 = \text{const} \} \). We can further fix the exponential mapping uniquely by the requirement that all transverse leaves (the chains) are canonically, up to a non-zero real scalar \( \mu \), parameterized by a real parameter \( \xi \in \mathbb{R} \) as

\[
\{ x_1 = \text{const}, \quad x_2 = \mu \xi \}.
\]

In addition, it follows from the construction of the connection that the canonical \( k \)-form \( \psi \) on tangent leaves looks as

\[
\psi = \mu(x_1)^k
\]
at any point \( q \in \mathbb{R}^2 \).

Considering now the complexification \( \Sigma^\mathbb{C} = \mathbb{C}^2 \) of the totally real surface \( \Sigma \), we obtain the complexification \( \nabla^\mathbb{C} \) of the (real-analytic) connection \( \nabla \) as a holomorphic connection on \( \Sigma^\mathbb{C} \). The complexifications \( T^\mathbb{C} \) and \( S^\mathbb{C} \) of the foliations \( T \) and \( S \) respectively form a pair of foliations of \( \mathbb{C}^2 \), transverse to each other. The complexification \( \exp^\mathbb{C}(Z) \) gives the exponential mapping for \( \nabla^\mathbb{C} \), and the map \( (\exp^\mathbb{C})^{-1} \) provides canonical (normal) coordinates \((z_1, z_2)\) for \((M, p)\).

Now, in order to prove Theorem 3, it is sufficient to prove the following proposition.

**Proposition 6.1.** Let \((M, p)\) and \((M^*, p^*)\) be germs of two real-analytic hypersurfaces of the same type \( k \geq 3 \) as above, \( \Sigma \) and \( \Sigma^* \) their Levi degeneracy sets, and \( \nabla^\mathbb{C} \) and \( (\nabla^*)^\mathbb{C} \) the corresponding canonical complexified connections. Let \((N, 0)\) and \((N^*, 0)\) be two normal forms of \((M, p)\) and \((M^*, p^*)\), given by normal coordinates for the connections \( \nabla \) and \( \nabla^* \), respectively. Then any biholomorphism \( F : (N, 0) \mapsto (N^*, 0) \) is a linear mapping, as in (1.5).
Proof. Normal coordinates for the connections $\nabla^C$ and $(\nabla^*)^C$, respectively, are defined up to a choice of parameterization on the vertical leaves $t_p$ (which, in turn, is reduced to a scalar $\mu \in \mathbb{R}$, $\mu \neq 0$, see Section 5). First notice that the map $F$ must preserve the leaves $\{z_1 = \text{const}\}$, $\{z_2 = \text{const}\}$, thus it has the form

$$z_1 \mapsto f(z_1), \; z_2 \mapsto g(z_2).$$

Further, $F$ preserves the parameterization on the vertical leaves, so that $g$ has the form

$$g(w) = \mu w, \; \mu \neq 0.$$

Finally, $F$ must preserve the canonical form $\psi$, which is a real multiple of $(z_1)^{k-1}\bar{z}_1$ at each point, thus $f$ looks as

$$f(z_1) = (\mu)^{1/k}z_1.$$

This proves the proposition. $\square$

Theorem 3 is proved now.
