Abstract

Enterotoxigenic Escherichia coli (ETEC) is the most common and global cause of neonatal calf diarrhea, but there is a little information regarding calf ETEC strains in Argentina. In this study, five ETEC isolates from diarrheic dairy calves (2–10 d old) from Buenos Aires and Cordoba, Argentina were characterized on the basis of virulence gene (VG) pattern, O:H serotyping, hemolytic phenotype, phylogenetic group affiliation, antimicrobial (AM) resistance profile, and presence of integron class 1 and 2. The five isolates were examined by polymerase chain reaction (PCR) for the presence of 18 bovine VGs and showed the following genotypes: F5*/F4+sta− (D242), F5*/sta+ (D158), F5+sta− (D157), F5+sta− (D151-9), and F5+sta+ (D151-5). These VGs confere pathogenic potential and most of them are associated with the ETEC pathotype. The five isolates showed a non-hemolytic phenotype, belonged to five different serotypes: O101:H−, O141:H+, O60:H+, ONT:H10, and ONT:H+, and were assigned to the phylogenetic group A by the quadruplex Clermont PCR method. The AM resistance of the three isolates D242, D157, and D151-5 was determined by agar disk diffusion method for 24 AMs and they exhibited a multi-resistance phenotype (resistance to four different AM classes: Cephalosporins, Penicillins, Macrolides, and Ansamycins). In addition, class 1 integrons were found in the isolate D151-5 containing the dfrA17-aadA5 gene cassette and in the bovine ETEC reference strain FV10191 containing the dfrA11-aadA1 gene cassette. The present study revealed for the first time the occurrence of multi-resistant ETEC associated with neonatal diarrhea in dairy calves in Argentina. This finding may be used for diagnostic and therapeutic purposes.

Keywords: Antimicrobial resistance, Dairy cattle, Escherichia coli, Neonatal diarrhea, Virulence gene.

Introduction

Escherichia coli is a commensal bacterium widespread in the intestine of warm-blooded animals and humans, and a pathogen that can induce enteric and extraintestinal diseases (Kaper et al., 2004). Neonatal diarrhea (ND) in calves is an acute enteric disease of economic importance which is characterized by watery diarrhea, dehydration, loss of body weight, and sometimes death of infected calves associated with multiple enteric pathogens (e.g., viruses, bacteria, and protozoa) (Cho and Yoon, 2014; Foster and Smith, 2009). Enterotoxigenic Escherichia coli (ETEC) is a commonly cause of ND in young calves in the first 4 d of life to 2 wk when other enteropathogens are involved (Acres, 1985; Holland, 1990; Foster and Smith, 2009). Its pathogenicity involves adherence of the pathogen to the small intestine by means of specific fimbrial adhesion factors to bind host cells receptors in newborn calves and production of one or several exotoxins responsible for the disease (Kaper et al., 2004). Major virulence factors of calf ETEC isolates are the fimbriae F5 (K99) and F41, and the heat-stable enterotoxin (Sta) (Acres, 1985). F5 and sta genes are usually located on the same plasmid that can also carry antibiotic resistance genes, while F41 is encoded on chromosome (Dubreuil et al., 2016).

Since 1980, studies have reported the isolation of E. coli strains from calves with diarrhea in Argentina. Three of them did not identify ETEC strains in any sample using immunological methods (F5) and the suckling mouse model (Sta) (Bellinzoni et al., 1990; Campero et al., 1985; Mercado et al., 2003). Other surveys identified few ETEC strains from sick calves (Barrandeguy et al., 1988; Cornaglia et al., 1992; Odeon, 1980) but the strains found were not genetically characterized. Picco et al. (2015) examined samples from diarrheic and non-diarrheic dairy calves of Cordoba by PCR and they found seven virulence profiles (including the VGs F5, F41, and sta) compatible with ETEC in 12 isolates (n = 39). However, they did not provide information concerning the serotype, antimicrobials (AMs) resistance or phylogroup. In the last 8 yr, we analyzed the presence of 18 VGs of hundreds of samples by PCR from outbreaks and sporadic cases of ND in Argentinean farms submitted to our diagnostic laboratory and we did not detect ETEC strains up to now. The objective of this work was to report the pheno- and genotypic characterization of five ETEC isolates recovered from diarrheic dairy calves in relation to VG pattern, O:H...
serotyping, hemolytic phenotype, phylogenetic group affiliation, AM resistance profile, and presence of integron class 1 and 2.

Materials and Methods

Escherichia coli isolates

The five isolates characterized in this work (D242, D158, D157, D151-9, and D151-5) were obtained by veterinarians from samples submitted to the Bacteriology Diagnostic Laboratory at the Balcarce Experimental Station (INTA, Argentina) in 2014–2015. The isolates were obtained from feces of 2- to 10-d-old diarrheic calves (Holando-Argentino) from three dairy farms in Cordoba (D242) and Buenos Aires (D158 and D157 isolated from different calves; D151-5 and D151-9 isolated from one calf), Argentina. The isolate D242 was previously reported E. coli F5+ by lateral flow immunoassay (Anigen Rapid BovI-D4 Ag Test Kit—Bionote, Inc., Korea). The samples were plated onto MacConkey agar (MAC, Difco, MD) and incubated at 37°C for 18 h. Afterward, the confluent bacterial growth of each sample plate was harvested and stored at the room temperature in nutrient agar 0.75% (p/v) prepared with nutritive agar (11.5 g/l; Difco, MD) and nutritive broth (4 g/l; Difco, MD) until analyzed by PCR. For this purpose, bacterial growth was plated on MAC and incubated in the above conditions. Ten individual lactose positive colonies with a phenotypic appearance consistent with E. coli were transferred to tryptic soy agar (TSA) (Difco, MD). The isolates were identified as E. coli by standard biochemical procedures according to the Bergey’s Manual (positive reactions for indole and methyl red, negative reactions for Voges-P, citrate utilization, urease, and hydrogen sulfide). They were not sub-cultured more than twice before being examined for the presence of virulence genes.

Detection of hemolysin activity

Escherichia coli isolates were tested for the production of a hemolytic phenotype on Columbia Blood Agar Base (Oxoid, Basingstoke, UK) with 7% v/v defibrinated bovine blood. Production of hemolysis as a zone of lysis surrounding the bacterial growth was read after overnight incubation at 37°C. The ETEC strains FV 10189 from swine and FV 10191 from bovine were used as positive and negative control, respectively.

DNA extraction, detection, and sequencing of VGs

DNA extraction

Bacteria were harvested and suspended in 300 µl (confluent growth and five-colony pools) or 150 µl (individual colonies) of sterile distilled water and boiled for 5 min to release the DNA. After centrifugation (11,000 × g at 4°C for 3 min), the supernatant was used as a template for the PCR reaction.

Detection of VGs by PCR

The 18 VGs analyzed in this work are listed in Table 1. Amplification of bacterial DNA was performed in a total volume of 30 µl containing 7 µl of the crude lysate, 150 ng of each oligonucleotide primer, 200 µM (each) dATP, dGTP, dCTP, and dTTP (Promega, WI); 1X Green GoTaq Reaction Buffer (1.5 mM MgCl2, pH 8.5), and 1 U of Go Taq DNA polymerase (Promega, WI). Primer nucleotide sequences used in this study to test the presence of VGs and predicted amplicon sizes are shown in Table 1. General conditions for the single PCR were initial DNA denaturation at 94°C for 3 min followed by 35 cycles of denaturation at 94°C for 40 sec, primer annealing at 48°C–66°C (Table 1) for 1 min and extension for 72°C for 3 min followed by a final extension at 72°C for 3 min (except for afà8, clpG, and EHEChlyA where the conditions described by Le Bouguene et al. (2001), Bertin et al. (1998), and Schmidt et al. (1995), respectively were followed) performed in a Px2 Thermal Cycler (Thermo Electron Corporation, MA).

One DNA from two E. coli reference strains (kindly provided from LREC, University of Santiago de Compostela, Lugo, Spain) was included in every PCR procedure for the detection of VGs as a positive control. Reference E. coli strains used as positive controls included: EDL933 (stx1, stx2, eae, and EHhlyA), 146N (stx1, stx2, and eae), FV 10187 (stx2e, sta, stb, and F18), FV 10188 (eltA, stb, K88, and east1), FV 10189 (eltA, sta, stb, F18, and east1), FV 10191 (sta, F5, and F41), B41 (F5 and F41), FV 10192 (f17G), FV 10193 (papC, afà8, and iucD), FV 10194 (afà8 and iucD) FV 10195 (cnfl, pap, sfa, HlyA, and iucD), FV 10196 (cdt, sfa, K1, and iucD), S5 (cnf2, cdt-III, and f17G), FVL16 (papC and sfa), 31A (clpG), J96 (cnf1, cdt-IV, and papC), 239KH89 (cnfl, papC, and afà8-E-8), EPEC (hfp and eae), 02/02 (EHEChlyA and eae). Escherichia coli DH5α and distilled water were used in every PCR as a negative control.

From each PCR positive confluent growth for particular VG, 10 E. coli-like colonies were sub-cultured from a MAC agar plate to a TSA agar plate. At first, two five-colony pools were analyzed for different VG and a subsequent PCR was performed to analyzed individual colonies from positive pools.

The amplified products were analyzed by standard gel electrophoresis on a 1.6% agarose gel with SYBR® Safe DNA Gel Stain and visualized under the UV light. The sizes of the amplified products were compared with those of positive controls and DNA molecular marker (100–1,000 pb).

Sequencing

The identity of the F5, F41, sta, and iucD PCR products was confirmed by DNA sequencing. Nucleotide sequence of VGs and integron PCR products was determined on both DNA strands using a BigDye Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems, CA) and a Genetic Analyzer 3130xl (Applied Biosystems) according to the manual and were submitted to GenBank database (Table 2). Reaction conditions and the primers used for the PCR and sequencing reactions are shown in Table 1.
Table 1. PCR primers sequence, amplicon size and conditions for amplifications used in this study.

**Determination of phylogenetic group**
Affiliation of *E. coli* isolates to phylogenetic group A, B1, B2, C, D, E, and F was determined by quadruplex PCR method as described by Clermont et al. (2013).

**Detection of integrase gene and integron analysis**
The presence of class 1 and 2 integrase was tested by PCR using primers specific for the integrase genes *intI1* and *intI2*, respectively (Table 1). The DNA templates for PCR were prepared as described previously. PCR amplification was performed in 25 µl volumes containing 5-µl bacterial template DNA, 0.4 µM each primer, 200-µM dNTP (Promega, WI), 1X Green GoTaq Reaction Buffer (1.5 µM MgCl<sub>2</sub>, pH 8.5), 1.5 µM MgCl<sub>2</sub> and 1 U of Go Taq DNA polymerase (Promega, WI). The PCR conditions were initial denaturation at 94°C for 3 min, 35 cycles of denaturation for 1 min at 94°C, annealing for 30 sec at 52°C, and extension for 2 min at 72°C, and a final extension for 5 min at 72°C. To characterize the gene cassettes found in the variable region of class 1 integrons from the isolate D151-5 and the reference strain FV10191, PCRs were performed using the primers 5′CS/3′CS and *dhfrA1/sulIR* (Table 1) as described previously. PCRs products were detected by electrophoresis on agarose gels as mentioned previously. The gene cassettes were identified by nucleotide sequencing.

**Determination of serotype**
O and H types were determined by microagglutination technique in plates and tubes as described by Guinée et
al. (1981) and modified by Blanco et al. (1996) using all available O (O1–O175) antisera plus six putative new O antigens (OX176–OX181) and H (H1–H56) antisera (Pradel et al., 2000).

**AM susceptibility testing**

AM susceptibilities of the isolates were evaluated on Mueller–Hinton agar (Oxoid, Basingstoke, UK) by the Kirby–Bauer disk-diffusion method (Bauer et al., 1966) according to the Clinical and Laboratory Standards Institute (2010) guidelines (including the AM disk content). Three isolates D151-5, D157, and D242 (one from each dairy farm) were tested for resistance to 24 AMs including the most prescribed by veterinarians in the region where the samples were collected. The AM used were Amicacin, Amoxicillinum–Clavulanic Acid (AMC), Cefaclor (CEC), Cefotaxime, Cephalexin (CL), Cephalonium (CMN), Cephalothin (CEF), Cloxacillin (OB), Colistin, Compound Sulphonamides (S3), Enrofloxacin (ENR), Erythromycin (ERY), Florfenicol, Gentamicin, Nalidixic Acid (NA), Norfloxacain (NOR), Ofloxacin, Oxytetracycline (OT), Polymyxin B, Rifampicin, Streptomycin (S), Tetracycline (TET), Tilmicosin (TIL), and Trimethoprim-Sulphamethoxazole (TMS). All AM susceptibility discs were provided from OXOID, Basingstoke, UK. *Escherichia coli* ATCC 25922 was used as the reference strain for quality control of the AMs tested. Multi-resistant strain was defined as resistant to three or more AM classes (Magiorakos et al., 2012).

**Results and Discussion**

Five isolates from diarrheic dairy calves were characterized in relation to the presence of 18 VGs. The VG profiles for the five isolates are shown in Table 2. The identity of the F5, F41, sta, and iucD PCR products was confirmed by DNA sequencing (Table 2). The five isolates were found to carry the fimbrial gene F5 which has been long considered to be the major adherence factor in bovine ETEC strains (Acres, 1985; Foster and Smith, 2009). Three of them (D242, D158, and D157) carried both the fimbriae F5 and the enterotoxin sta (*stap*, the porcine *sta* variant) genes, including one isolate (D242) with the F5*/F41*/sta* genotype which is considered a typical VG combination for bovine ETEC strains (Güler et al., 2008; Mainil et al., 1990, 1992; Nagy and Fekete, 1999). The isolate D151-9 was positive only for the F5 fimbrial gene. In addition, the isolate D151-5 carried both F5 and iucD genes. *iucD* gene is part of the aerobactin operon (*iucABCD iutA*) encoding the siderophore aerobactin and its receptor which is normally found on plasmids (Herrero et al., 1988). IucD protein catalyzes the initial step in aerobactin biosynthesis (Herrero, et al., 1988) and it is frequently found in extra-intestinal *E. coli* strains (ExPEC) (Köhler and Dobrindt, 2011). This unusual combination of the F5 fimbrial gene and the *iucD* aerobactin gene observed in this hybrid strain could be explained on the basis of horizontal gene transfer between cells, which enables the exchange of genetic material located on mobile elements (transposons, integrons, or plasmids) among related or unrelated bacterial species (Ahmed et al., 2008; Hacker and Kaper, 2000). The potential for a given *E. coli* strain to possess different combinations or sets of virulence genes could lead to the emergence of new pathotypes. Consistent with this hypothesis, we found this hybrid strain (ETEC/ExPEC) with a combination of VGs from different pathotypes. No enterotoxin gene was detected in the isolates D151-9 and D151-5 which may suggest its loss during infection or laboratory culture. The loss of plasmid borne genes is not uncommon in ETEC (Francis, 2002).

The ETEC isolates belonged to five different serotypes: O101:H, O141:H, O60:H, ONT:H10, and ONT:H (Table 2). The serotypes are diverse containing combinations of VGs associated with the F5* ETEC pathotype. The serogroup O101 was reported previously in bovine ETEC strains in other countries as France, China, Iran, and Japan (Acres, 1985; Du et al., 2005; Mainil et al., 1990; Shams et al., 2012; Yamamoto and Nakazawa, 1997) which is considered the most common serogroup of F5* F41* ETEC strains from calves together with the serogroup O9 (Acres, 1985; Nagy and Fekete, 1999). This serogroup was also determined in this study in the reference strain FV101191 (F5/F41/sta) isolated from bovine in Spain (Table 2). The serotypes O141:H and O60:H identified in this work were not previously reported among bovine ETEC strains. These two serotypes have been detected in strains from piglets with post-weaning diarrhea in several countries (Garabal et al., 1996; Klemm, 1994; Vu-Khac et al., 2006, 2007). The O141:H porcine isolate contained the F18, sta, and sib (Vu-Khac et al., 2006), while the O141:H bovine isolate contained the F5 and sta. In the case of the O60:H, porcine isolate contained the F18 and east1 (Vu-Khac et al., 2006), while the O60:H bovine isolate contained the F5 and sta. These differences suggest that these two serotypes can host a variety of VGs including F5 and F18 fimbrial genes associated to receptors which are expressed in at different animal ages (Acres, 1985; Francis, 2002; Nagy and Fekete, 1999). This novel association between O141:H and O60:H serotypes and calves reported here support the idea that the process to originate pathogen strains is present in the particular sampled environment (a dairy farm). The same idea could be extended to the non-typeable serogroups of D151-5 (ONT:H) and D151-9 (ONT:H10).

The production of hemolysis (particularly β-hemolysis) is a trait often associated with pathogen *E. coli* strains from animals (Smith, 1963). Thus, the routine diagnosis of pathogenic *E. coli* strains includes the hemolytic phenotype as presumptive evidence of pathogenic potential. No hemolytic activity on CBA was detected.
The phylogenetic relationship was determined according to the Clermont phylogroup method based on chromosomal markers. The quadruplex genotype of the five isolates was 242 (+ - + -), D158 (+ - + -), D157 (+ - - -), D151-9 (+ + - +), and D151-5 (+ + + +) (Table 2). Based on these quadruplex genotypes obtained, all the isolated were assigned to the phylogenetic group A, which is associated with commensal E. coli strains (Clermont et al., 2013). These isolates may have acquired the VGs by movil genetic elements (except for the chromosomal F41 adhesin gene) through horizontal gene transfer and became pathogens from commensal bacteria (Ahmed et al., 2008; Hacker and Kaper, 2000). The bovine gastrointestinal tract is a natural reservoir for commensal and pathogenic E. coli strains with high phylogenetic and genotypic diversity. To be considered as ETEC, the presence of toxin and/or fimbrial genes (Acres, 1985; Foster and Smith, 2009; Leimbach et al., 2017; Rodas et al., 2011), it is more relevant than the chromosomal background. In humans, results have indicated that ETEC may have acquired virulence plasmids at several independent occasions during evolution and that the chromosomal genetic background is diverse and not specific for ETEC (Steinsland et al., 2010). Our results with bovine isolates may indicate that the chromosomal background, as measured by serotyping and phylotyping, is diverse and it is associated to commensal strains but further analyses including multilocus sequence typing (MLST) or whole genome sequencing are needed to determine chromosomal relationships.

Among the 24 AMs tested, the three isolates D242, D157, and D151-5 exhibited resistance at least to five AMs (AMC–ERY–OB–RFA–TIL) which can be included in four different AM classes (Cephalosporins, Penicillins, Macrolides, and Ansamycins). In addition, the isolate D151-5 exhibited resistance to Quinolones, Tetracyclines, and Sulphonamides (Table 2). Three isolates showed resistance to TIL that is commonly used in veterinary practice and, the isolates in our study showed resistance to AMC, ERY, OB, and RFA which are unusual AMs in veterinary practice. The isolates shared resistances to more than three AM classes and for this reason are classified as multiresistant according to Magiorakos et al. (2012). This multi-resistant phenotype pointed out the possible presence of integrons which are considered to play the main role in the emergence of multiresistance (Mazel, 2006). Among the five ETEC isolates and reference strains (FV10191 and FV10189), the isolate D151-5 and the reference strain FV10191 were positive for the presence of integrase class 1 and the five isolates and reference strains (FV10191 and FV10189) were negative for the integrase class 2. Gene cassettes for the two class 1 integrons detected were amplified and sequenced. Both integrons included the dfr and aad gene alleles encoding dihydrofolate reductases and adenylyltransferase, respectively (Table 2). The integron of D151-5 included the genes dfrA17 that confer resistance to trimethoprim and aadA5 that confer resistance to spectinomycin but not to streptomycin (White et al., 2000) in the variable region, and the gene Sul1 (resistance to sulfonamide) in the 3′-conserved segment (3′CS) (White et al., 2000). Consistent with this result, the isolate D151-5 is trimethoprim and sulfonamide resistant and streptomycin susceptible. This gene cassette array dfrA17-aadA5 was detected in Europe, Africa, Asia, and Australia from cattle in the last years (Stokes and Gillings, 2011; INTEGRALL database http://integrall.bio.ua.pt/), and this cassette array was recently identified in America from a calf in Uruguay (Umpiérez et al., 2017). The integron identified in the reference strain FV10191, harbored the cassette array dfrA1-aadA1 which is frequently found in E. coli (Stokes and Gillings, 2011; INTEGRALL database http://integrall.bio.ua.pt/). The resistances to trimethoprim-sulfamethoxazole and sulfonamides exhibited by the strain FV10191 correlated with the presence of dfr and sul1 in the class 1 integron, but the susceptibility to streptomycin (300 µg) showed in this strain was not concordant to the aadA1 gene identified in the cassette arrays. This could be related to the integron location, the distance of the aadA1 gene to the promoter or the low-level streptomycin resistance conferred by the aadA gene compared with the high-level streptomycin resistance conferred by the strA-strB genes (Sunde and Norström, 2005).

Molecular studies allow for a comprehensive characterization of the isolates involved in bovine diseases. The current study provides evidence that the ETEC pathotype was isolated from diarrheic dairy calves in the central region of Argentina based on diagnostic cases but not represent the situation in dairy calves in Argentina. We found a high level of AM resistance which may be associated with the selective pressure caused by antibiotic use on the dairy farms where the isolates were collected. The broad use of AMs in animal production may lead to the emergence and dissemination of AM-resistant bacterial pathogens which could be considered a reservoir of virulence and resistance genes in the environment and pose a potential threat to public health. This evidence emphasizes the urgent need for effective surveillance and control. Further research on a large sample size is proposed to attribute an effect of the ETEC pathotype in diarrheic neonatal calves in our country.
