EXISTENCE OF GLOBAL WEAK SOLUTIONS OF A SYSTEM OF EQUATIONS MODELING FERROHYDRODYNAMICS AND RELAXATION TO THE EQUILIBRIUM

RICARDO H. NOCHETTO, KONSTANTINA TRIVISA, AND FRANZISKA WEBER

Abstract. This article establishes the global existence of weak solutions to a model proposed by Rosensweig [26] for the dynamics of ferrofluids. The system is expressed by the conservation of linear momentum, the incompressibility condition, the conservation of angular momentum, and the evolution of the magnetization. The existence proof is inspired by the DiPerna-Lions theory of renormalized solutions. In addition, the rigorous relaxation limit of the equations of ferrohydrodynamics towards the quasi-equilibrium is investigated. The proof relies on the relative entropy method, which involves constructing a suitable functional, analyzing its time evolution and obtaining convergence results for the sequence of approximating solutions.

1. Introduction

1.1. Motivation. Ferrofluids are stable colloidal dispersions of nano-sized particles of ferro- or ferrimagnetic particles in a carrier liquid. These complex fluids have an array of technological applications. Ferrofluids have the capability of reducing friction, making them useful in a variety of electronic and transportation applications. They can also be used as a liquid seal in many electronic devices, for instance in computer hard-drives where they can be utilized to form a seal around the rotating shaft [22, 27] or in loudspeakers for cooling and damping unwanted resonances [15].

A major benefit of ferrofluids is that the liquids can be forced to flow via the positioning and strength of the magnetic field and so the fluid can be positioned precisely, as a result they have found a variety of biomedical applications. They have been instrumental in transporting medications to exact locations within the human body (drug delivery), they have been of use as contrasting agents for Magnetic Resonance Imaging (MRI) scans. More recently, ferrofluids have been of use in on-going research investigations aiming at the creation of an artificial heart; by surrounding the heart with magnets, the ferrofluid fixed to frame of the heart will expand and contract when needed, imitating the pumping of the real organ. We refer the reader to [21] and [32] for an overview of relevant biomedical applications. Although our understanding of the dynamics of ferrofluids has evolved in recent years, many aspects of ferrohydrodynamics remain largely unexplored, especially experimentally. This article is part of a research program which aims at enhancing our understanding of the properties and dynamics of ferrofluids through the analysis of models that are relevant to practical applications.

1.2. Governing Equations. The goal of this work is the rigorous investigation of the solvability of the equations proposed by Rosensweig [26] that describe the flow of an incompressible ferrofluid subjected to an external magnetic field. In this model, the dynamics of the linear velocity \( \mathbf{u} \), the angular momentum \( \mathbf{w} \) and the magnetization \( \mathbf{m} \) on a bounded simply connected domain \( \Omega \subset \mathbb{R}^d \), \( d = 2, 3 \), are governed by the conservation of linear momentum, the incompressibility condition, the conservation of angular momentum, the transport of the magnetization and the influence of a magnetic field \( \mathbf{h} \) as follows (cf. [26, 25, 20]):

\[ \text{Date: October 26, 2018.} \]
\[ 2010 \text{ Mathematics Subject Classification. Primary: 35Q30, 76N10; Secondary: 92C17.} \]
\[ \text{Key words and phrases. Ferrofluids, hydrodynamic limit, relaxation to equilibrium, relative entropy, magnetohydrodynamics.} \]
\[ \mathbf{u}_t + (\mathbf{u} \cdot \nabla)\mathbf{u} - (\nu + \nu_r)\Delta \mathbf{u} + \nabla p = 2\nu_r \text{curl} \mathbf{w} + \mu_0 (\mathbf{m} \cdot \nabla)\mathbf{h}, \quad (1.1a) \]
\[ \text{div} \mathbf{u} = 0, \quad (1.1b) \]
\[ \mathbf{w}_t + (\mathbf{u} \cdot \nabla)\mathbf{w} - c_1 \Delta \mathbf{w} - c_2 \nabla \text{div} \mathbf{w} + 4\nu_r \mathbf{w} = 2\nu_r \text{curl} \mathbf{u} + \mu_0 \mathbf{m} \times \mathbf{h}, \quad (1.1c) \]
\[ \mathbf{m}_t + (\mathbf{u} \cdot \nabla)\mathbf{m} = \mathbf{w} \times \mathbf{m} - \frac{1}{r} (\mathbf{m} - \kappa_0 \mathbf{h}), \quad (1.1d) \]
\[ \text{curl} \mathbf{h} = 0, \quad (1.1e) \]
\[ \text{div} (\mathbf{h} + \mathbf{m}) = 0, \quad (1.1f) \]

with suitable boundary conditions. The effective magnetizing field \( \mathbf{h} \) is given by
\[ \mathbf{h} = \mathbf{h}_a + \mathbf{h}_d. \quad (1.2) \]

Here, \( \mathbf{h}_a \) denotes the so-called applied magnetic field which is assumed to be smooth and divergence free, whereas \( \mathbf{h}_d \) is the demagnetizing field.

The forcing term
\[ \mathbf{F} = \mu_0 (\mathbf{m} \cdot \nabla)\mathbf{h} \]

in the linear momentum equation is the so-called Kelvin force. The term \( \mu_0 \mathbf{m} \) represents the vector moment per unit volume.

The model is derived under the following physically grounded, yet restrictive, hypotheses:

(A1) The ferromagnetic particles are spherical.
(A2) The ferrofluid is a monodisperse mixture, in the sense that the ferromagnetic particles are of the same mass/size.
(A3) The density of ferromagnetic particles (number of particles per unit volume) in the carrier liquid is considered to be homogeneous.
(A4) No agglomeration, clumping, anisotropic behavior (e.g. formation of chains), nor particle-to-particle interactions are considered.
(A5) The induced fields (\( \mathbf{m} \) and \( \mathbf{h}_d \)) are unable to perturb the applied magnetic field \( \mathbf{h}_a \).

Even though these assumptions might restrict the applicability of the Rosensweig model, there is a large class of physical situations in which they apply (cf. [26]). The derivation follows the strategy that is common in the theory of thermodynamics, namely we start stating fundamental principles such as the conservation of linear and angular momentum, the conservation of mass and the evolution of the magnetization in the presence of stress tensors and other quantities which satisfy rather general constitutive laws. Next, one proceeds by writing the Clausius-Duhem inequality and with the calculation the entropy production rate, which according to the second law of thermodynamics is assumed to be a nonnegative measure. This requirement imposes additional restrictions on various quantities (tensors, forces and parameters) in the system, which result to the form of the nonlinear system stated above. In particular, the material constants \( \nu, \nu_r, \mu_0, j, c_\alpha, c_d, c_0, \kappa_0 \) are assumed to be nonnegative and are chosen in such a way so that the Clausius-Duhem inequality is satisfied (cf. [26, 20, 14]).

Whenever the magnetization \( \mathbf{m} \) is small, \( \mathbf{h} \approx \mathbf{h}_a \). It is therefore often neglected in the analysis and one ends up with a reduced system involving only equations (1.1a)–(1.1d) (i.e., the magnetic field \( \mathbf{m} \) is assumed to be given and not a solution of the magnetostatics equations (1.1e)–(1.1f)). The analysis of the reduced system is significantly easier, however, recent numerical simulations for a related two-phase flow model [17] indicate that the reduced system may not be able to capture the whole physical behavior of ferrofluids, for example the famous Rosensweig instability can only be reproduced when the magnetic field is the solution of the magnetostatics equation (1.1e)–(1.1f) (see Figures 6 and 7 in that article [17]). We will therefore focus here on the analysis of the full system (1.1).

We refer the reader to Rinaldi and Zahn [24], Sunil, Chand and Bharti [29], Zahn and Greer [33] for further remarks.
1.2.1. Initial and Boundary Conditions. We assume that the initial data is such that
\begin{align}
\mathbf{u}(0, x) &= \mathbf{u}_0(x) \in L^2_{\text{div}}(\Omega), \quad \mathbf{w}(0, x) = \mathbf{w}_0(x) \in L^2(\Omega), \quad \mathbf{m}(0, x) = \mathbf{m}_0(x) \in L^2(\Omega). \tag{1.3}
\end{align}

The external applied field \( \mathbf{h} \) is assumed to be smooth in space and time and divergence free. Moreover, we use the boundary conditions on \( \Gamma := \partial\Omega \)
\begin{align}
\mathbf{u}(t, \cdot)|_{\Gamma} = 0, \quad \mathbf{w}(t, \cdot)|_{\Gamma} = 0, \quad t \in [0, T]. \tag{1.4}
\end{align}

Under the assumption that the domain \( \Omega \) is simply-connected, we can write \( \mathbf{h} = \nabla \varphi \), by equation (1.1e), and so equation (1.1f) becomes an elliptic equation for the potential \( \varphi \),
\begin{align}
-\Delta \varphi = \text{div} \mathbf{m}. \tag{1.5}
\end{align}

We use Neumann boundary conditions for \( \mathbf{h} \),
\begin{align}
\frac{\partial \varphi}{\partial n} = (\mathbf{h}_n - \mathbf{m}) \cdot \mathbf{n} \quad \text{on } [0, T] \times \Gamma \quad \text{with} \quad \int_{\Omega} \varphi(t, x) dx = 0, \tag{1.6}
\end{align}
where \( \mathbf{n} \) is the unit outer normal on \( \Gamma \), these boundary conditions can be physically motivated, see [18, Section 2.2] for a discussion of boundary conditions.

Existence of global weak solutions to the system (1.1a)-(1.1f) in the presence of additional diffusion \( \sigma \Delta \mathbf{m}, \sigma > 0 \), in (1.1e) has been shown by Amirat et al. [2]. Results on the local in time existence of strong solutions has been shown [1]. To the best of our knowledge our article is the first that establishes the global existence of weak solutions in the absence of additional diffusion in the magnetization equation. In particular, we prove the following existence result,

**Theorem 1.1** (Global Existence). Assume the initial data \( (\mathbf{u}_0, \mathbf{w}_0, \mathbf{m}_0) \) satisfies (1.3), the effective magnetizing field is given by (1.2) and the applied magnetizing field \( \mathbf{h}_n \) is smooth and divergence free. Then the problem (1.1a)-(1.11) with boundary conditions (1.4) and (1.6) has a global weak solution \( \mathcal{U} := (\mathbf{u}, \mathbf{w}, \mathbf{m}, \mathbf{h}) \), as in Definition 2.1, satisfying the energy inequality
\begin{align}
\int_\Omega E(\mathcal{U})(t) dx + \int_0^t \int_\Omega D(\mathcal{U})(s) \, dx \, ds \leq \int_\Omega E(\mathcal{U})(0) dx + \mu_0 \int_0^t \int_\Omega \partial_t \mathbf{h}_n \cdot \mathbf{h} \, dx \, ds, \tag{1.7}
\end{align}
where the energy \( E \) is defined by
\begin{align}
E(\mathcal{U}) &= \frac{1}{2} \left( |\mathbf{u}|^2 + |\mathbf{w}|^2 + \frac{\mu_0}{\kappa_0} |\mathbf{m}|^2 + \mu_0 |\mathbf{h}|^2 \right), \tag{1.8}
\end{align}
and the dissipation functional \( D \) is defined by
\begin{align}
D(\mathcal{U}) &= \left( \nu \|\nabla \mathbf{u}\|^2 + c_1 \|\nabla \mathbf{w}\|^2 + c_2 |\text{div} \mathbf{w}|^2 + \nu_r |\text{curl} \mathbf{u} - 2\mathbf{w}|^2 + \frac{\mu_0}{\tau \kappa_0} |\mathbf{m} - \kappa_0 \mathbf{h}|^2 \right). \tag{1.9}
\end{align}

**Remark 1.2.** The technique used to prove this result can be extended in a straightforward fashion to prove existence of global weak solutions of the diffusive interface model for two-phase ferrofluid flows that was introduced in [17].

This theorem is established by constructing a suitable sequence of approximating solutions inspired by the result of Amirat et al. [2]. The lack of sufficient regularity in the sequence of approximate solutions, as obtained employing the energy estimate, presents a big challenge in the analysis. More specifically, the main energy bound only yields \( \mathbf{m} \in L^\infty(0, T; L^2(\Omega)) \) uniformly for the approximating sequence of solutions. The reader should contrast this space setting to the result in [2], where the additional artificial dissipation term in the magnetization equation yields \( H^1 \)-regularity in space.

Another major difficulty arises due to the presence of the a priori unbounded Kelvin force term \( \mu_0 (\mathbf{m} \cdot \nabla) \mathbf{h} \) in the momentum equation. This challenge is addressed by deriving a new identity (see Lemma 2.3) that allows us to define the Kelvin force term in a distributional sense, and the definition of weak solutions of (1.1) is modified accordingly in light of the new formulation.

In addition, passing to the limit in the approximations requires us to establish compactness in \( L^2 \) for the approximating sequence of the magnetization \( \mathbf{m} \). This is achieved by proving that the magnetization is ‘renormalized’ in the spirit of DiPerna-Lions theory for compressible fluids [12, 13].
Combining this new feature of the equation with an additional identity obtained for the weak limits of the magnetization and the magnetic field from the magnetostatics equation assists in establishing the result.

The long term goal of this research effort is the construction of convergent numerical schemes for the approximation of this nonlinear system.

1.3. Relaxation time and quasi-equilibrium. In practical applications, the parameter \( \tau > 0 \) in equation (1.1d), the relaxation time, is often very small. According to [28], it is given by

\[
\frac{1}{\tau} = \frac{1}{\tau_B} + \frac{1}{\tau_N}, \quad \text{or} \quad \tau = \frac{\tau_B \tau_N}{\tau_N + \tau_B},
\]

where \( \tau_B \) is the Brownian time and \( \tau_N \) is the Néel time. In Brownian relaxation, the magnetization vector \( m \) rotates synchronically with the particle, while in the Néel relaxation mechanism, the magnetization vector \( m \) rotates inside the particle and the particle itself does not rotate. Depending on the particle size, one or the other mechanism dominates. For particles with a smaller diameter than the so-called Shliomis’ diameter \( d_S \), the Néel time satisfies \( \tau_N \ll \tau_B \) and hence \( \tau \approx \tau_N \). For bigger particles, \( \tau_B \ll \tau_N \) and hence \( \tau \approx \tau_B \). The Néel time can be very small: For example for particles with diameter \( d \approx (0.3 - 0.5)d_S \) it is of order \( \tau \approx \tau_N \approx 10^{-9} \)s and hence the magnetization vector \( m \) becomes parallel to the magnetic field vector \( h \) almost immediately. For the opposite case, \( \tau \approx \tau_B \approx 10^{-5} - 10^{-4} \)s and hence the magnetization vector does not need to be parallel to \( h \) [28]. Rinaldi [23, page 54] states that the relaxation time may be of the order \( \tau \approx 10^{-7} - 10^{-5} \)s. One may therefore assume that it is of interest to investigate the behavior solutions of (1.1) as \( \tau \to 0 \). Formally, setting \( \tau = 0 \) in (1.1), we obtain the following system:

\[
U_t + (U \cdot \nabla)U - (\nu + \nu_r)\Delta U + \nabla P = 2\nu_r \operatorname{curl} W + \mu_0 (M \cdot \nabla)H, \quad (1.10a)
\]

\[
\operatorname{div} U = 0, \quad (1.10b)
\]

\[
jW_t + j(U \cdot \nabla)W - c_1 \Delta W - c_2 \nabla \operatorname{div} W + 4\nu_r W = 2\nu_r \operatorname{curl} U, \quad (1.10c)
\]

\[
M = \kappa_0 H, \quad (1.10d)
\]

\[
\operatorname{curl} H = 0, \quad (1.10e)
\]

\[
\operatorname{div}(H + M) = 0, \quad (1.10f)
\]

with boundary conditions

\[
U = 0, \quad W = 0, \quad H \cdot n = \frac{1}{1 + \kappa_0} h_a \cdot h, \quad \text{on } [0,T] \times \partial \Omega.
\]

The second objective of this article is to establish with rigorous arguments that under suitable assumptions on the initial data, we have that in the relaxation limit \( \tau \to 0 \),

\[
m \to \kappa_0 H
\]

and the sequence of solutions \((u_\tau, w_\tau, m_\tau, h_\tau)\) converges to a solution of (1.10) when \( \tau \to 0 \). In fact, the following can be shown rigorously:

**Theorem 1.3.** Denote \( \mathcal{U}_\tau := (u_\tau, w_\tau, m_\tau, h_\tau) \), \( h_\tau = \nabla \varphi_\tau \) the solution of system (1.1) for a given \( \tau > 0 \). Then as \( \tau \to 0 \), a subsequence of \( \{\mathcal{U}_\tau\}_{\tau > 0} \) converges in \( L^2([0,T] \times \Omega) \) to a weak solution of (1.10).

When the solution of the limiting system (1.10) is smooth, which is the case for short times and smooth data and in two space dimensions for smooth enough data (this is shown in Appendix A), we show a convergence rate in \( \tau \) for the approximate solutions of (1.1):

**Theorem 1.4.** If the solution of (1.10) satisfies \( U, W \in L^\infty(0,T;\text{Lip}(\Omega)), H = \nabla \Phi \in L^2(0,T;H^1(\Omega)), \)

\[
\partial_t H \in L^2([0,T] \times \Omega); \quad \text{and the initial data for (1.1) and (1.10) satisfy}
\]

\[
||u_0 - U_0||^2_{L^2(\Omega)} + ||w_0 - W_0||^2_{L^2(\Omega)} + ||m_0 - M_0||^2_{L^2(\Omega)} \leq C \tau,
\]

then the solutions \( \mathcal{U}_\tau \) of (1.1) converge as \( \tau \to 0 \) to the solution of the limiting system (1.10) at the rate:
\[ \| u_r - U \|_{L^2(\Omega)} (t) + \| w_r - W \|_{L^2(\Omega)} (t) + \| m_r - M \|_{L^2(\Omega)} (t) \]
\[ + \| h_r - H \|_{L^2(\Omega)} (t) + \| \nabla (u_r - U) \|_{L^2([0,T] \times \Omega)} + \| \nabla (w_r - W) \|_{L^2([0,T] \times \Omega)} \leq C \sqrt{T} (1 + \exp (Ct)). \]

The proof of the latter result uses the relative entropy method that was introduced by Dafermos [5, 6] and DiPerna [7] in the context of hyperbolic systems of conservation laws, see also [4]. One constructs a suitable relative entropy functional that quantifies the difference between \( U_r \) and the solution of the limiting system \( \mathcal{U}_0 = (U, W, M, H) \) in \( L^2 \) and bounds its time evolution in terms of \( \tau \). This is achieved by a careful estimation of all the resulting growth terms using the available bounds for the solution in an appropriate way.

1.4. Outline of this article. The outline of this article is as follows: In Section 2 we present preliminaries and the energy law that governs the Rosensweig model. In Section 3 we present the proof of the global existence results for the Rosensweig model. Section 4 is devoted to the relaxation to equilibrium and the proof of Theorems 1.3 and 1.4. Finally, in Appendix A we discuss the global existence of classical solutions in \( \mathbb{R}^2 \).

2. Preliminaries

We start by introducing some notation: We denote by \( L^2_{\text{div}} (\Omega) \) the space of divergence free \( L^2(\Omega) \) function and by \( H^1_{\text{div}} (\Omega) \) the space of divergence free functions in \( H^1(\Omega) \) (these can be obtained as the closures of \( C^\infty_0 (\Omega) \cap \{ \text{div} u = 0 \} \) in \( L^2(\Omega) \) and \( H^1(\Omega) \) respectively (c.f. [30]):

\[ L^2_{\text{div}} (\Omega) = \{ u \in L^2(\Omega); \text{div} u = 0, u \cdot n|_{\partial \Omega} = 0 \}, \]
\[ H^1_{\text{div}} (\Omega) = \{ u \in H^1(\Omega); \text{div} u = 0, u|_{\partial \Omega} = 0 \}. \]

For a Banach space \( X \) we let \( C_w (0, T; X) \) be the space of functions that are weakly continuous in time, that is, if \( v \in C_w (0, T; X) \), then for any \( s \to t, \)
\[ \{ v(t_s), g \} \to \{ v(t), g \}, \quad \text{for } s \to t, \quad \forall g \in X^*, \]

where we denoted by \( X^* \) the dual space of \( X \) and by \( \langle \cdot, \cdot \rangle \) the dual product on \( X, X^* \). Now we are ready to define a notion of weak solution for the Rosenzweig system (1.1):

**Definition 2.1** (Distributional solution of the Rosensweig model). Let \( T > 0, \Omega \subset \mathbb{R}^d, d = 2, 3 \), a smooth, simply connected domain. We say that \( \mathcal{U} = (u, w, m, h) \) is a global weak solution of the system (1.1) if the following conditions are satisfied:

(i) The solution \( \mathcal{U} = (u, w, m, h) \) satisfies the regularity requirements:
\[ u \in L^\infty (0, T; L^2_{\text{div}} (\Omega)) \cap L^2 (0, T; H^1_{\text{div}} (\Omega)) \cap C_w (0, T; L^2 (\Omega)) \]
\[ w \in L^\infty (0, T; L^2 (\Omega)) \cap L^2 (0, T; H^1 (\Omega)) \cap C_w (0, T; L^2 (\Omega)) \]
\[ m \in L^\infty (0, T; L^2 (\Omega)) \cap C_w (0, T; L^2 (\Omega)) \]
\[ h \in L^\infty (0, T; L^2 (\Omega)) \cap C_w (0, T; L^2 (\Omega)); \]

(ii) the function \( h \) is such that \( h = \nabla \varphi, \) where \( \varphi \in L^\infty (0, T; H^1 (\Omega)) \) and satisfies for all \( \psi \in H^1 (\Omega), \)
\[ \int_\Omega \nabla \varphi \cdot \nabla \psi dx = \int_\Omega (h_a - m) \cdot \nabla \psi dx, \]
with Neumann boundary conditions:

\[ \frac{\partial \varphi}{\partial n} = (h_a - m) \cdot n \quad \text{on } [0, T] \times \Gamma \quad \text{with } \int_\Omega \varphi (t, x) dx = 0; \]

(iii) Equations (1.1a)–(1.1d) hold weakly, that is for any test functions \( \psi_i \in C^1_c ([0, T] \times \Omega) \)
\[ i = 1, \ldots, 4 \] 
with vanishing trace on \( \partial \Omega \) and \( \text{div} \psi_i (t, x) = 0 \) for all \( (t, x) \in [0, T] \times \Omega, \)
\[ \int_0^T \int_\Omega \{ u \cdot \partial_t \psi_1 + ((u \cdot \nabla) \psi_1) \cdot u - (\nu + \nu_r) \nabla u \cdot \nabla \psi_1 \} dx dt + \int_\Omega u_0 \cdot \psi_1 (0, x) dx \]
\[ = \int_0^T \int_\Omega [ -2 \nu_r w \cdot \text{curl} \psi_1 + \mu_0 ((m + h) \cdot \nabla) \psi_1 \cdot h] dx dt \]
\[ \int_{\Omega} \mathbf{u}(t, x) \cdot \nabla \psi_2(t, x) dx = 0, \quad \text{a.e. } t \in [0, T] \]
\[ \int_{0}^{T} \int_{\Omega} [\mathbf{w} \cdot \partial_t \psi_3 + ((\mathbf{u} \cdot \nabla)\psi_3) \cdot \mathbf{w} - c_1 \nabla \psi_3 \cdot \nabla \psi_3 - c_2 \text{div } \mathbf{w} \text{ div } \psi_3] \, dx \, dt + \int_{\Omega} \mathbf{w}_0 \cdot \psi_3(0, x) dx \]
\[ = \int_{0}^{T} \int_{\Omega} [4\nu \mathbf{w} \cdot \psi_3 - 2\nu_0 \mathbf{u} \cdot \text{curl } \psi_3 - \mu_0 (\mathbf{m} \times \mathbf{h}) \cdot \psi_3] \, dx \, dt \]
\[ \int_{0}^{T} \int_{\Omega} [\mathbf{m} \cdot \partial_t \psi_4 + (\mathbf{u} \cdot \nabla)\psi_4 \cdot \mathbf{m}] \, dx \, dt + \int_{\Omega} \mathbf{m}_0 \cdot \psi_4(0, x) dx \]
\[ = \int_{0}^{T} \int_{\Omega} \left[ -(\mathbf{w} \times \mathbf{m}) \cdot \psi_4 + \frac{1}{\tau} (\mathbf{m} - \kappa_0 \mathbf{h}) \cdot \psi_4 \right] \, dx \, dt \]

where \( \mathbf{u}_0 \in L^2_{\text{div}}(\Omega) \), \( \mathbf{w}_0, \mathbf{m}_0 \in L^2(\Omega) \) are the initial conditions;

(iv) The solution \( \mathcal{U} := (\mathbf{u}, \mathbf{w}, \mathbf{m}, \mathbf{h}) \) satisfies the following energy inequality,

\[ \int_{\Omega} E(\mathcal{U})(t) \, dx + \int_{0}^{t} \int_{\Omega} D(\mathcal{U})(s) \, dx \, ds \leq \int_{\Omega} E(\mathcal{U})(0) \, dx + \mu_0 \int_{0}^{t} \int_{\Omega} \partial_s \mathbf{h}_a \cdot \mathbf{h} \, dx \, ds. \tag{2.1} \]

where the energy \( E \) is defined by

\[ E(\mathcal{U}) = \frac{1}{2} \left( |\mathbf{u}|^2 + |\mathbf{w}|^2 + \frac{\mu_0}{\kappa_0} |\mathbf{m}|^2 + \mu_0 |\mathbf{h}|^2 \right), \tag{2.2} \]

and the dissipation functional \( D \) is defined by

\[ D(\mathcal{U}) = \left( \nu |\nabla \mathbf{u}|^2 + c_1 |\nabla \mathbf{w}|^2 + c_2 \text{div } \mathbf{w}^2 + \nu_0 |\text{curl } \mathbf{u} - 2\mathbf{w}|^2 + \frac{\mu_0}{\tau \kappa_0} |\mathbf{m} - \kappa_0 \mathbf{h}|^2 \right). \tag{2.3} \]

**Remark 2.2.** For smooth solutions, the energy inequality (2.1) in fact becomes an equality and can be obtained by taking the inner product of equation (1.1a) with \( \mathbf{u} \), equation (1.1c) with \( \mathbf{w} \), equation (1.1d) with \( \left( \frac{\mu_0}{\kappa_0} \mathbf{m} - \mu_0 \mathbf{h} \right) \) and the time-differentiated equation (1.1f) with \(-\mu_0 \varphi\), adding all of them, integrating over \( \Omega \), and then integrating by parts a couple of times.

2.1. **Auxiliary results.** If \( \mathbf{h} \) does not have more spatial regularity than \( L^2(\Omega) \), the Kelvin force \( \mu_0 (\mathbf{m} \cdot \nabla) \mathbf{h} \) in (1.1a) is not well-defined, not even in a weak sense. Therefore, we used the following identity to define weak solutions in Definition 2.1, which allows us to make sense of the Kelvin force for \( \mathbf{m} \) and \( \mathbf{h} \) with little regularity.

**Lemma 2.3.** Any sufficiently smooth solution of (1.1) satisfies

\[ (\mathbf{m} \cdot \nabla) \mathbf{h} = \text{div } ((\mathbf{m} + \kappa_0 \mathbf{h}) \otimes \mathbf{h}) - \frac{1}{2} \nabla (|\mathbf{h}|^2). \tag{2.4} \]

**Proof.** We write the differential operators in terms of their components:

\[ ((\mathbf{m} \cdot \nabla) \mathbf{h})^{(j)} = \sum_{i=1}^{3} m^{(i)} \partial_i h^{(j)} \]
\[ = \sum_{i=1}^{3} \partial_i \left( m^{(i)} h^{(j)} \right) - \sum_{i=1}^{3} \partial_i m^{(i)} h^{(j)} \]
\[ = \text{div } \left( \mathbf{m} h^{(j)} \right) - \text{div } \mathbf{m} h^{(j)}. \tag{2.5} \]

We use equation (1.1f) to replace the divergence of \( \mathbf{m} \) in the last expression:

\[ \text{div } \left( \mathbf{m} h^{(j)} \right) - \text{div } \mathbf{m} h^{(j)} = \text{div } \left( \mathbf{m} h^{(j)} \right) + \text{div } \mathbf{h} h^{(j)}. \tag{2.6} \]
By (1.1e), \( h \) is the gradient of a potential \( \varphi \), therefore
\[
\text{div } h^{(j)} = \Delta \varphi \partial_j \varphi
\]
\[
= \sum_{i=1}^{3} \partial_{ii} \varphi \partial_j \varphi
\]
\[
= \sum_{i=1}^{3} (\partial_i (\partial_i \varphi \partial_j \varphi) - \partial_i \varphi \partial_i \partial_j \varphi)
\]
\[
= \sum_{i=1}^{3} \left( \partial_i (\partial_i \varphi \partial_j \varphi) - \frac{1}{2} \partial_j |\partial_i \varphi|^2 \right)
\]
\[
= \text{div} (\nabla \varphi \partial_j \varphi) - \frac{1}{2} \partial_j(|\nabla \varphi|^2)
\]
\[
= \text{div} \left( h h^{(j)} \right) - \frac{1}{2} \partial_j (|h|^2),
\]
where we replaced \( \nabla \varphi \) by \( h \) again in the last equation. We combine the last calculation with (2.5) and (2.6) and obtain
\[
(m \cdot \nabla)h^{(j)} = \text{div} (mh^{(j)}) + \text{div} (h h^{(j)}) - \frac{1}{2} \partial_j (|h|^2)
\]
\[
= \text{div} \left( (m + h) h^{(j)} \right) - \frac{1}{2} \partial_j (|h|^2),
\]
which is the component form of (2.4).

**Remark 2.4.** If we only require \( m \in L^2(\Omega), h \in H^1(\Omega) \), identity (2.4) still holds in the sense of distributions for smooth enough and compactly supported in \( \Omega \) test functions \( \psi \):
\[
\int_{\Omega} ((m + h) \cdot \nabla) \psi \, dx = - \int_{\Omega} \left[ \left( (m + h) \cdot \nabla \right) \psi \cdot h - \frac{1}{2} |h|^2 \text{div} \psi \right] \, dx. \tag{2.7}
\]
The right hand side of equation (2.7) is bounded even if \( m, h \in L^2(\Omega) \) (and \( \psi \) is smooth enough, i.e., in \( C^1(\Omega) \) with bounded derivatives). It therefore allows us to define weak solutions of the Rosensweig model (1.1) when \( m \) and \( h \in L^2(\Omega) \) only.

### 3. Existence of global weak solutions

In this section we prove the global existence of weak solutions to system (1.1), by constructing a sequence of solutions that satisfies an approximating system and by establishing that the sequence converges to a solution of (1.1). As an approximating sequence, we use weak solutions of the regularized system,
\[
\begin{align*}
\dot{u}^\sigma + (u^\sigma \cdot \nabla)u^\sigma - (\nu + \nu_r) \Delta u^\sigma + \nabla p^\sigma &= 2\nu_r \text{curl } w^\sigma + \mu_0 (m^\sigma \cdot \nabla)h^\sigma, & \text{(3.1a)} \\
\text{div } u^\sigma &= 0, & \text{(3.1b)} \\
\dot{w}^\sigma + (u^\sigma \cdot \nabla)w^\sigma - c_1 \Delta w^\sigma - c_2 \nabla \text{div } w^\sigma + 4\nu_r w^\sigma &= 2\nu_r \text{curl } u^\sigma + \mu_0 m^\sigma \times h^\sigma, & \text{(3.1c)} \\
\dot{m}^\sigma + (u^\sigma \cdot \nabla)m^\sigma - \sigma \Delta m^\sigma &= w^\sigma \times m^\sigma - \frac{1}{\tau} (m^\sigma - \kappa_0 h^\sigma), & \text{(3.1d)} \\
\text{curl } h^\sigma &= 0, & \text{(3.1e)} \\
\text{div}(h^\sigma + m^\sigma) &= 0, & \text{(3.1f)}
\end{align*}
\]
which is identical to (1.1) up to the extra term \( \sigma \Delta m^\sigma \) in the magnetization equation (3.1d), where \( \sigma > 0 \), that yields additional regularity for \( m^\sigma \) and so also for \( h^\sigma \). In the literature, this regularized equation for \( m^\sigma \) is sometimes called a Bloch-Torrey type equation [2, 31, 11] because it was proposed by Torrey [31] and can be seen as a generalization of the Bloch equations [3] to describe situations in which the diffusion of the spin magnetic moment is not negligible.
Since equation (3.1d) is parabolic for \( \sigma > 0 \), additional boundary conditions for \( \mathbf{m}^\sigma \) have to be imposed in contrast to the case \( \sigma = 0 \). A discussion of several reasonable choices of boundary conditions for \( \mathbf{m}^\sigma \) can be found in [18, Section 2.3]. We use the natural boundary conditions

\[
\operatorname{curl} \mathbf{m}^\sigma \times \mathbf{n} = 0, \quad \operatorname{div} \mathbf{m}^\sigma = 0, \quad \text{on } (0, T) \times \partial \Omega,
\]

which allow obtaining an energy-stable system for the chosen boundary conditions for \( \mathbf{h}^\sigma \) (i.e. (1.6)). The energy inequality is needed to show existence of weak solutions of the system (3.1) using a Galerkin approximation, as it was done for a slightly different system by Amirat, Hamdache, Murat in [2]. In particular, in their system, equation (3.1f) is replaced by

\[
\operatorname{div}(\mathbf{h}^\sigma + \mathbf{m}^\sigma) = f, \quad \mathbf{h}^\sigma = \nabla \varphi^\sigma,
\]

with boundary conditions

\[
\frac{\partial \varphi}{\partial n} = 0, \quad \operatorname{curl} \mathbf{m}^\sigma \times \mathbf{n} = 0, \quad \mathbf{m}^\sigma \cdot \mathbf{n} = 0, \quad \text{on } (0, T) \times \partial \Omega,
\]

for \( \varphi^\sigma \) and \( \mathbf{m}^\sigma \) instead of (3.2). Up to this difference, which implies that \( \mathbf{m}^\sigma \) is sought in a different space, one defines weak solutions of (3.1) in the same way as in [2] (see upcoming Definition 3.1) and also existence of weak solutions is proved in the same way (the modifications needed due to the changed boundary conditions are sketched in Appendix B).

The solution \( \mathbf{m}^\sigma(t) \) now lies for almost every \( t \in [0, T] \) in the space

\[
\mathcal{K} := \{q \in L^2(\Omega) \mid \operatorname{div} q \in L^2(\Omega), \operatorname{curl} q \in L^2(\Omega)\} = H(\operatorname{div}) \cap H(\operatorname{curl}),
\]

equipped with the inner product

\[
(g_1, g_2) := \int_\Omega q_1 \cdot q_2 \, dx + \int_\Omega \operatorname{div} q_1 \operatorname{div} q_2 \, dx + \int_\Omega \operatorname{curl} q_1 \cdot \operatorname{curl} q_2 \, dx.
\]

Then, weak solutions of (3.1) are defined as follows:

**Definition 3.1 (Distributional solution of (3.1), [2]).** Let \( T > 0, \Omega \subset \mathbb{R}^3 \) a smooth, simply connected domain. We say that \( \mathcal{U}^\sigma := (\mathbf{u}^\sigma, \mathbf{w}^\sigma, \mathbf{m}^\sigma, \mathbf{h}^\sigma) \) is a global weak solution of the system (3.1) if the following conditions are satisfied:

(i) The solution \( \mathcal{U}^\sigma = (\mathbf{u}^\sigma, \mathbf{w}^\sigma, \mathbf{m}^\sigma, \mathbf{h}^\sigma) \) has the regularity properties:

- \( \mathbf{u}^\sigma \in L^\infty(0, T; L^2_{\operatorname{div}}(\Omega)) \cap L^2(0, T; H^1_{\operatorname{div}}(\Omega)) \cap C_w([0, T]; L^2_{\operatorname{div}}(\Omega)) \)
- \( \mathbf{w}^\sigma \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)) \cap C_w([0, T]; L^2(\Omega)) \)
- \( \mathbf{m}^\sigma \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; K) \cap C_w([0, T]; L^2(\Omega)) \)
- \( \mathbf{h}^\sigma \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)) \);

(ii) the function \( \mathbf{h}^\sigma \) is such that \( \mathbf{h}^\sigma = \nabla \varphi^\sigma \), where \( \varphi^\sigma \in L^\infty(0, T; H^1(\Omega)) \cap L^2(0, T; H^2(\Omega)) \) solves the problem

\[
-\Delta \varphi^\sigma = \operatorname{div} \mathbf{m}^\sigma, \quad \text{in } [0, T] \times \Omega,
\]

\[
\frac{\partial \varphi^\sigma}{\partial n} = (\mathbf{h}_a - \mathbf{m}^\sigma) \cdot \mathbf{n}, \quad \text{on } [0, T] \times \partial \Omega, \quad \int_\Omega \varphi^\sigma \, dx = 0, \quad \text{in } (0, T),
\]

in the distributional sense;

(iii) Equations (3.1a)–(3.1d) hold weakly, that is, for any test functions \( \psi_1 \in H^1_{\operatorname{div}}(\Omega), \psi_2 \in H^1_0(\Omega), \psi_3 \in \mathcal{K} \), we have

\[
\frac{d}{dt} \int_\Omega \mathbf{u}^\sigma \cdot \psi_1 \, dx + \int_\Omega [(\mathbf{u}^\sigma \cdot \nabla) \mathbf{u}^\sigma] \cdot \psi_1 \, dx + (\nu + \nu_r) \int_\Omega \nabla \mathbf{u}^\sigma : \nabla \psi_1 \, dx
\]

\[
= \mu_0 \int_\Omega (\mathbf{m}^\sigma \cdot \nabla) \mathbf{h}^\sigma \cdot \psi_1 \, dx + 2\nu_r \int_\Omega \operatorname{curl} \mathbf{w}^\sigma \cdot \psi_1 \, dx, \quad \text{in } \mathcal{D}'((0, T)),
\]

\[
\mathbf{u}^\sigma(0, \cdot) = \mathbf{u}_0;
\]

\[
\frac{d}{dt} \int_\Omega \mathbf{w}^\sigma \cdot \psi_2 \, dx + \int_\Omega [(\mathbf{u}^\sigma \cdot \nabla) \mathbf{w}^\sigma] \cdot \psi_2 \, dx + c_1 \int_\Omega \nabla \mathbf{w}^\sigma : \nabla \psi_2 \, dx + c_2 \int_\Omega \operatorname{div} \mathbf{w}^\sigma \, \operatorname{div} \psi_2 \, dx
\]
\[
\begin{align*}
\frac{d}{dt} \int_{\Omega} u^\sigma : \psi_1 \, dx + \int_{\Omega} (u^\sigma \cdot \nabla)(u^\sigma) : \psi_1 \, dx + \nu_\tau \int_{\Omega} \nabla u^\sigma : \nabla \psi_1 \, dx \\
= -\mu_0 \int_{\Omega} \left( (m^\sigma + h^\sigma) \cdot \psi_1 \right) \cdot h^\sigma \, dx + 2\nu_\tau \int_{\Omega} \nabla w^\sigma : \psi_1 \, dx, \quad \text{in } D'(0, T),
\end{align*}
\]

Remark 3.2. Using Lemma 2.3, the weak formulation for \( u^\sigma \) can be rewritten as

\[
\frac{d}{dt} \int_{\Omega} u^\sigma \cdot \psi_1 \, dx + \int_{\Omega} (u^\sigma \cdot \nabla)u^\sigma \cdot \psi_1 \, dx + (\nu + \nu_\tau) \int_{\Omega} \nabla u^\sigma : \nabla \psi_1 \, dx \\
= -\mu_0 \int_{\Omega} \left( (m^\sigma + h^\sigma) \cdot \psi_1 \right) \cdot h^\sigma \, dx + 2\nu_\tau \int_{\Omega} \nabla w^\sigma : \psi_1 \, dx, \quad \text{in } D'(0, T).
\]

3.1. Energy inequality. In [2, Theorem 1], it was proved that weak solutions as in Definition 3.1 exist if \( u_0 \in L^2_{div}(\Omega), w_0, m_0 \in L^2(\Omega) \) and that they satisfy in addition an energy inequality. The energy inequality proved there is slightly different from the one we are going to use in the following, but can be proved in the same way. Formally, one can use \( \psi_1 = u^\sigma, \psi_2 = w^\sigma \) and \( \psi_3 = \mu_0 m^\sigma - \mu_0 h^\sigma \) as test functions in (3.5), (3.6), and (3.7) respectively, and add; take the derivative of (3.4a), multiply with \( \mu_0 \varphi^\sigma \), integrate over \( \Omega \) and add as well, to obtain,

\[
\begin{align*}
\frac{1}{2} \frac{d}{dt} \int_{\Omega} \left( |u^\sigma|^2 + |w^\sigma|^2 + \frac{\mu_0}{\kappa_0} |m^\sigma|^2 + \mu_0 |h^\sigma|^2 \right) \, dx \\
+ \int_{\Omega} \left( \nu |\nabla u^\sigma|^2 + c_1 |\nabla w^\sigma|^2 + c_2 |\nabla m^\sigma|^2 + c_3 |\nabla h^\sigma|^2 \right) \, dx \\
+ \sigma \mu_0 \int_{\Omega} \left( \frac{1}{\kappa_0} |\nabla m^\sigma|^2 + \frac{1}{\kappa_0} |\nabla h^\sigma|^2 \right) \, dx = \mu_0 \int_{\partial \Omega} \partial_t h_n \cdot h^\sigma \, dx,
\end{align*}
\]

(3.8)

where we have also used that

\[
\Delta m^\sigma = -\nabla \cdot \nabla m^\sigma + \nabla \cdot \nabla m^\sigma,
\]

and that this identity combined with (3.4a), and the boundary conditions for \( m^\sigma \) and \( h^\sigma \), yields

\[
\begin{align*}
\int_{\Omega} \Delta m^\sigma \cdot h^\sigma \, dx &= -\int_{\Omega} (\nabla \cdot \nabla m^\sigma) \cdot h^\sigma \, dx \\
&= -\int_{\Omega} \nabla \cdot \nabla m^\sigma \cdot h_n \, dx - \int_{\Omega} \nabla m^\sigma \cdot \nabla h_n \, dx \\
&\quad + \int_{\partial \Omega} \nabla m^\sigma \cdot \nabla h_n \, dS + \int_{\partial \Omega} \nabla m^\sigma \cdot (h^\sigma \cdot n) \, dS \\
&= -\int_{\Omega} \nabla m^\sigma \cdot \nabla h^\sigma \, dx \\
&\quad + \int_{\partial \Omega} |\nabla m^\sigma|^2 \, dS.
\end{align*}
\]

Since all of this has to be done at the level of the Galerkin approximation first, then passing to the limit in the approximation, (3.8) holds only as an inequality.

Remark 3.3. The existence proof in [2] also shows that \( m^\sigma \) satisfies

\[
\frac{1}{2} \int_{\Omega} |m^\sigma|^2(t) \, dx + \sigma \int_0^t \int_{\Omega} (|\nabla m^\sigma|^2 + |\nabla m^\sigma|^2) \, dx \, ds
\]
\begin{equation}
\leq \frac{1}{2} \int_{\Omega} |m_0^i|^2 dx - \frac{1}{\tau} \int_0^t \int_{\Omega} \mathbf{m}^\prime \cdot (\mathbf{m}^\prime - \kappa_0 \mathbf{h}^\prime) dx ds \tag{3.9}
\end{equation}

3.2. Renormalized solutions. In the proof of Proposition 3.6, we will make use of the fact that the magnetization equation (1.1d) has the structure of a transport equation. In fact, we prove here that \( \mathbf{m} \) is ‘renormalized’ as in the sense of DiPerna and Lions [8, 13, 19]. We will need the following lemma:

**Lemma 3.4.** Let \( \mathbf{m} \in L^\infty(0, T; L^2(\Omega)) \) be a distributional solution of

\( \partial_t \mathbf{m} + (\mathbf{u} \cdot \nabla) \mathbf{m} = \mathbf{w} \times \mathbf{m} - \frac{1}{\tau} (\mathbf{m} - \kappa_0 \mathbf{h}) \),

\( \tag{3.10} \)

for given \( \mathbf{u} \in L^\infty(0, T; L^2_{\text{div}}(\Omega)) \cap L^2(0, T; H^1_{\text{div}}(\Omega)) \), \( \mathbf{w} \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)) \) and \( \mathbf{h} \in L^\infty(0, T; L^2(\Omega)) \). Then the components \( m^{(i)} \) of \( \mathbf{m} \) satisfy for any \( b \in C^1(\mathbb{R}) \) with \( b(\cdot) \) bounded,

\[ \partial_t m^{(i)} + \mathbf{u} \cdot \nabla b(m^{(i)}) = b'(m^{(i)}) (\mathbf{w} \times \mathbf{m})^{(i)} - \frac{1}{\tau} b'(m^{(i)}) (m^{(i)} - \kappa_0 h^{(i)}), \]

in the sense of distributions.

**Proof.** First we see that we can extend \( \mathbf{u}, \mathbf{w} \) and \( \mathbf{m} \) by zero outside \( \Omega \) to make the functions of the whole \( \mathbb{R}^d \), since \( \mathbf{w} \) and \( \mathbf{u} \) have zero trace and \( \mathbf{m} \) is assumed to be a function of \( L^2(\Omega) \) only with no requirements on the boundary traces. Since (3.10) holds in the sense of distributions, we can use a mollifier \( \omega_\varepsilon(x) = \varepsilon^{-d} \omega(x/\varepsilon) \), where \( \omega \in C^\infty_c(\mathbb{R}^d) \) is supported on \([-1, 1]^d\) and normalized \( \int_{\mathbb{R}^d} \omega dx = 1 \), as a test function in one component \( m^{(i)} \) of \( \mathbf{m} \). Denoting \( m^{(i)}_\varepsilon := m^{(i)} * \omega_\varepsilon \),

\( h^{(i)}_\varepsilon := h^{(i)} * \omega_\varepsilon \), we observe that the components \( m^{(i)}_\varepsilon \) of \( \mathbf{m}_\varepsilon \) satisfy the following equation pointwise in \( (t,x) \):

\[ \partial_t m^{(i)}_\varepsilon + (\mathbf{u} \cdot \nabla m^{(i)}_\varepsilon) * \omega_\varepsilon = (\mathbf{w} \times \mathbf{m})^{(i)} * \omega_\varepsilon - \frac{1}{\tau} b'(m^{(i)}_\varepsilon) (m^{(i)}_\varepsilon - \kappa_0 h^{(i)}_\varepsilon). \]

We can thus multiply this equation by \( b'(m^{(i)}_\varepsilon) \) and apply the chain rule:

\[ \partial_t b(m^{(i)}_\varepsilon) + b'(m^{(i)}_\varepsilon) (\mathbf{u} \cdot \nabla m^{(i)}_\varepsilon) * \omega_\varepsilon = b'(m^{(i)}_\varepsilon) (\mathbf{w} \times \mathbf{m})^{(i)} * \omega_\varepsilon - \frac{1}{\tau} b'(m^{(i)}_\varepsilon) (m^{(i)}_\varepsilon - \kappa_0 h^{(i)}_\varepsilon). \]

The term \( b'(m^{(i)}_\varepsilon) (\mathbf{u} \cdot \nabla m^{(i)}_\varepsilon) \) can be written as

\[ b'(m^{(i)}_\varepsilon) (\mathbf{u} \cdot \nabla m^{(i)}_\varepsilon) * \omega_\varepsilon = \mathbf{u} \cdot \nabla b(m^{(i)}_\varepsilon) + b'(m^{(i)}_\varepsilon) \left( (\mathbf{u} \cdot \nabla m^{(i)}_\varepsilon) * \omega_\varepsilon - u \cdot \nabla m^{(i)}_\varepsilon \right) \]

\[ := \mathbf{u} \cdot \nabla b(m^{(i)}_\varepsilon) + b'(m^{(i)}_\varepsilon) R_\varepsilon, \]

hence for any \( \psi \in C^\infty_c(\mathbb{R}^d) \)

\[ \int_{\mathbb{R}^d} b(m^{(i)}_\varepsilon(t,x)) \psi(x) dx - \int_{\mathbb{R}^d} b(m^{(i)}_\varepsilon(0,x)) \psi(x) dx - \int_0^t \int_{\mathbb{R}^d} b(m^{(i)}_\varepsilon) \mathbf{u} \cdot \nabla \psi(x) dx ds \]

\[ = \int_0^t \int_{\mathbb{R}^d} \left( b'(m^{(i)}_\varepsilon) (\mathbf{w} \times \mathbf{m})^{(i)} * \omega_\varepsilon - \frac{1}{\tau} b'(m^{(i)}_\varepsilon) (m^{(i)}_\varepsilon - \kappa_0 h^{(i)}_\varepsilon) \right) \psi dx ds \]

\[ - \int_0^t \int_{\mathbb{R}^d} b'(m^{(i)}_\varepsilon) R_\varepsilon \psi dx ds. \]

Since \( b \in C^1(\mathbb{R}) \) with bounded derivative, and \( m^{(i)}, h^{(i)} \in L^\infty(0, T; L^2(\mathbb{R}^d)) \), and \( \mathbf{u}, \mathbf{w} \in L^2(0, T; H^1(\Omega)) \), we can pass to the limit in all the terms except the term involving \( R_\varepsilon \). That one converges to zero in \( L^1_{\text{loc}}([0, \infty) \times \mathbb{R}^d) \) by [12, Lemma 2.3], therefore, since \( b'(\cdot) \) is bounded and \( \psi \) is compactly supported, the term involving \( R_\varepsilon \) converges to zero. We obtain in the limit \( \varepsilon \to 0 \)

\begin{equation}
\int_{\mathbb{R}^d} b(m^{(i)}(t,x)) \psi(x) dx - \int_{\mathbb{R}^d} b(m^{(i)}(0,x)) \psi(x) dx - \int_0^t \int_{\mathbb{R}^d} b(m^{(i)}) \mathbf{u} \cdot \nabla \psi(x) dx ds \\
= \int_0^t \int_{\mathbb{R}^d} \left( b'(m^{(i)}) (\mathbf{w} \times \mathbf{m})^{(i)} - \frac{1}{\tau} b'(m^{(i)}) (m^{(i)} - \kappa_0 h^{(i)}) \right) \psi dx ds. \tag{3.11}
\end{equation}
Instead of a test function $\psi$ only depending on space, we could also have used a test function $\psi \in C^\infty_c ([0, \infty) \times \mathbb{R}^d)$ and integrated by parts in the term involving the time derivative of $b(m(t))$. In that case, we obtain, after passing to the limit $\varepsilon \to 0$,

$$
\int_0^\infty \int_{\mathbb{R}^d} b(m(t)) \partial_t \psi dx dt + \int_{\mathbb{R}^d} b(m(0,x)) \psi(x) dx + \int_0^\infty \int_{\mathbb{R}^d} b(m(t)) u \cdot \nabla \psi dx dt
$$

$$
= -\int_0^\infty \int_{\mathbb{R}^d} \left( b'(m(t)) (w \times m) - \frac{1}{\tau} b'(m(t)) \left( m(t) - \kappa_0 h(t) \right) \right) \psi dx dt,
$$

which is what we wanted to prove (since $m(t), u$ and $w$ are all zero outside $\Omega$, we can replace the integration over $\mathbb{R}^d$ by the integration over $\Omega$).

Using that $m \in L^\infty (0,T; L^2(\Omega))$, we can use the previous lemma to prove the following special case:

**Lemma 3.5.** Let $m \in L^\infty (0,T; L^2(\Omega))$ be a distributional solution of

$$
\partial_t m + (u \cdot \nabla) m = w \times m - \frac{1}{\tau} (m - \kappa_0 h),
$$

for given $u \in L^\infty (0,T; L^2(\Omega)) \cap L^2 (0,T; H^1 (\Omega))$, $w \in L^\infty (0,T; L^2 (\Omega)) \cap L^2 (0,T; H^1_0 (\Omega))$, $h \in L^\infty (0,T; L^2 (\Omega))$ and initial data $m_0 \in L^2 (\Omega)$. Then $m$ satisfies for almost any $t \in [0,T]$,

$$
\frac{1}{2} \int_\Omega |m(t,x)|^2 dx = \frac{1}{2} \int_\Omega |m_0|^2 dx - \frac{1}{\tau} \int_0^t \int_\Omega (|m|^2 - \kappa_0 h \cdot m) dx ds. \quad (3.12)
$$

**Proof.** The starting point is identity (3.11). We would like to use $b(y) = y^2/2$ as a test function there and sum the equations for the components $m(i)$ over $i = 1,2,3$. However, such a $b$ does not satisfy the assumptions of Lemma 3.4 because it does not have bounded derivative which could potentially make the term involving $(w \times m)_{(i)}$ unbounded. Nonetheless, because the cross product is orthogonal to the two vectors involving it, that term would formally be zero when using $b'(m(i)) = m(i)$ after summing over $m(i)$. This indicates that to prove rigorously that we can use $b(y) = \sum_{i=1}^d b(y(i)) = \sum_{i=1}^d (y(i))^2/2$ as a test function, we should use approximations of it with gradient parallel to $m$. Given a finite $0 < K < \infty$, let $b_K^{(i)}$ be the function with $b_K^{(i)}(0) = 0$ and derivative

$$
(b_K^{(i)})' (m(i)) = m(i) \cdot \mathbb{1}_{|m| \leq K} + K \frac{m(i)}{|m|} \mathbb{1}_{|m| > K} = \begin{cases} m(i), & |m| \leq K, \\ K \frac{m(i)}{|m|}, & |m| > K, \end{cases}
$$

where $|m| = \sqrt{\sum_{i=1}^d (m(i))^2}$. The derivative of $b_K^{(i)}$ is obviously bounded by definition, however, it might be discontinuous. We can therefore convolve it with some smooth mollifier $\omega_\delta(x) = \delta^{-1} \omega(x/\delta)$ (as defined in Lemma 3.4 but in $\mathbb{R}$ instead of $\mathbb{R}^d$) to make it smooth and see that (3.11) holds for the primitive of the regularized $(b_K^{(i)})' := (b_K^{(i)})' \ast \omega_\delta$,

$$
\int_{\mathbb{R}^d} b_K^{(i)}(m(i)(t,x)) \psi(x) dx - \int_{\mathbb{R}^d} b_K^{(i)}(m(i)(0,x)) \psi(x) dx - \int_0^t \int_{\mathbb{R}^d} b_K^{(i)}(m(i)) u \cdot \nabla \psi(x) dx ds
$$

$$
= \int_0^t \int_{\mathbb{R}^d} \left( (b_K^{(i)})'(m(i)) (w \times m) - \frac{1}{\tau} (b_K^{(i)})'(m(i)) \left( m(i) - \kappa_0 h(i) \right) \right) \psi dx ds.
$$

Since $|b_K^{(i)}(m(i))| \leq C (|m(i)| + |m(i)|^2 \mathbb{1}_{|m(i)| \leq K})$ and $|(b_K^{(i)})'(m(i))| \leq CK$ uniformly in $\delta > 0$, $m(i), h(i) \in L^\infty (0,T; L^2 (\Omega))$, $u \in L^\infty (0,T; L^2 (\Omega))$ and $w \times m \in L^\infty ([0,T] \times \Omega)$ for some $\gamma > 1$ (using Sobolev embeddings for $w$), all the quantities in the last expression are uniformly integrable in $\delta > 0$ and we can pass to $\delta \to 0$ to obtain, by the properties of convolution

$$
\int_{\mathbb{R}^d} b_K^{(i)}(m(i)(t,x)) \psi(x) dx - \int_{\mathbb{R}^d} b_K^{(i)}(m(i)(0,x)) \psi(x) dx - \int_0^t \int_{\mathbb{R}^d} b_K^{(i)}(m(i)) u \cdot \nabla \psi(x) dx ds
$$

$$
= \int_0^t \int_{\mathbb{R}^d} \left( (b_K^{(i)})'(m(i)) (w \times m) - \frac{1}{\tau} (b_K^{(i)})'(m(i)) \left( m(i) - \kappa_0 h(i) \right) \right) \psi dx ds.
$$
Now, let us choose a smooth test function \( \psi \in C_c^\infty(\mathbb{R}^d) \) that satisfies \( \psi(x) \equiv 1 \) inside \( \Omega \), which implies that the convective term vanishes and we are left with

\[
\int_\Omega b_k^{(i)}(m^{(i)}(t, x))dx - \int_\Omega b_k^{(i)}(m^{(i)}(0, x))dx
= \int_0^t \int_\Omega \left( (b_k^{(i)})'(m^{(i)}) (w \times m)^{(i)} \right) dx ds - \frac{1}{\tau} \left( (b_k^{(i)})'(m^{(i)}) (m^{(i)} - \kappa_0 h^{(i)}) \right) dx ds.
\]

Now sum these identities over \( i = 1, \ldots, d \), define \( b_k(m) = \sum_{i=1}^d b_k^{(i)}(m^{(i)}) \) and notice that \((b_k^{(i)})', \ldots, (b_k^{(d)})')\) is parallel to \( m \) or zero, which means that

\[
\sum_{i=1}^d (b_k^{(i)})'(m^{(i)}) (w \times m)^{(i)} = 0, \quad \text{a.e. } (t, x) \in [0, \infty) \times \mathbb{R}^d,
\]

and thanks to the integrability properties on \( w \) and \( m \) in \( L^1([0, \infty) \times \mathbb{R}^d) \). So,

\[
\int_\Omega b_k(m(t, x))dx - \int_\Omega b_k(m_0)dx = \frac{1}{\tau} \sum_{i=1}^d \int_0^t \int_\Omega (b_k^{(i)})'(m^{(i)}) (m^{(i)} - \kappa_0 h^{(i)}) dx ds.
\]

All the quantities in the last identity are uniformly integrable with respect to \( K > 0 \), hence we can pass \( K \to \infty \), and get, since \( b_k(m) \to |m|^2/2 \) and \((b_k^{(1)})', \ldots, (b_k^{(d)})')\) \( \to m \), as \( K \to \infty \), equation (3.12).

3.3. Passing to the limit in the approximating sequence. We are now ready to prove existence of weak solutions of (1.1a)-(1.1f):

**Proposition 3.6.** Let \( \{\sigma_n\}_{n \in \mathbb{N}} \) be a sequence of nonnegative parameters such that \( \sigma_n \to \infty \) and denote \( U_n = (u_n, w_n, m_n, h_n, \varphi_n) := U_n^{\sigma_n} = (u_1^{\sigma_n}, w_1^{\sigma_n}, m_1^{\sigma_n}, h_1^{\sigma_n}, \varphi_1^{\sigma_n}) \) the solutions of (3.1) with \( \sigma = \sigma_n \). Assume that the initial data \( u_0, w_0 \) and \( m_0 \) satisfy (1.3), \( h_n \in L^\infty(0, T; L^2(\Omega)) \cap H^1(0, T; L^2(\Omega)) \) with div \( h_n = 0 \) a.e. and that the boundary conditions (1.4), (1.6) and (3.2) are satisfied. Then, as \( n \to \infty \), a subsequence of \( \{(u_n, w_n, m_n, h_n, \varphi_n)\}_{n \in \mathbb{N}} \) converges to a weak solution of (1.1) as in Definition 2.1.

**Proof.** From the energy estimate (3.8), we obtain that \( U_n \) satisfies, uniformly in \( n \),

\[
\begin{align*}
\{u_n\}_{n \in \mathbb{N}} &\subset L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)), \\
\{w_n\}_{n \in \mathbb{N}} &\subset L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)), \\
\{m_n\}_{n \in \mathbb{N}} &\subset L^\infty(0, T; L^2(\Omega)), \\
\{h_n\}_{n \in \mathbb{N}} &\subset L^\infty(0, T; L^2(\Omega)), \\
\{\varphi_n\}_{n \in \mathbb{N}} &\subset L^\infty(0, T; H^1(\Omega)), \\
\{\sqrt{\sigma_n} \text{ curl } m_n\}_{n \in \mathbb{N}}, \{\sqrt{\sigma_n} \text{ div } m_n\}_{n \in \mathbb{N}} &\subset L^2([0, T] \times \Omega),
\end{align*}
\]

Hence, from the Banach-Alaoglu theorem, we obtain that \( (u_n, w_n, m_n, h_n, \varphi_n)_{n \in \mathbb{N}} \) has a weak* convergent subsequence, which we denote by \( n \) again for convenience, such that as \( n \to \infty \),

\[
\begin{align*}
u_n &\rightharpoonup u, \quad \text{in } L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)), \\
w_n &\rightharpoonup w, \quad \text{in } L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)), \\
m_n &\rightharpoonup m, \quad \text{in } L^\infty(0, T; L^2(\Omega)), \\
h_n &\rightharpoonup h, \quad \text{in } L^\infty(0, T; L^2(\Omega)), \\
\varphi_n &\rightharpoonup \varphi, \quad \text{in } L^\infty(0, T; L^2(\Omega)),
\end{align*}
\]

where the limits satisfy

\[
\begin{align*}
\|u\|_{L^\infty([0, T]; L^2(\Omega)) \cap L^2([0, T]; H^1(\Omega))} &\leq C, \\
\|w\|_{L^\infty([0, T]; L^2(\Omega)) \cap L^2([0, T]; H^1(\Omega))} &\leq C, \\
\|m\|_{L^\infty([0, T]; L^2(\Omega))} &\leq C, \\
\|\varphi\|_{L^\infty([0, T]; H^1(\Omega))} &\leq C, \\
\|h\|_{L^\infty([0, T]; L^2(\Omega))} &\leq C.
\end{align*}
\]
Combining the equations for \( u_n \) and \( w_n \), (3.1a) and (3.1d) respectively, with the uniform bounds (3.13), we obtain by Sobolev embeddings that
\[
\{ \partial_t u_n \}_{n \in \mathbb{N}}, \{ \partial_t w_n \}_{n \in \mathbb{N}}, \{ \partial_t m_n \}_{n \in \mathbb{N}} \subset L^p(0, T; W^{-k,q}(\Omega)),
\]
for \( p, q > 1 \) and some \( k > 0 \) large enough. Therefore, we can use Aubin-Lion’s Lemma to obtain that
\[
u n \rightarrow \infty \quad u_n \rightarrow u, \quad w_n \rightarrow w, \quad \text{in } L^2([0, T] \times \Omega),
\]
as \( n \to \infty \) up to a subsequence. We use these convergence properties (3.14) and (3.16) to pass to the limit in the weak formulations of (3.1a), (3.1c) and (3.1d):
\[
0 = \int_0^T \int_{\Omega} \left[ u_n \cdot \partial_t \psi_1 + ((u_n \cdot \nabla) \psi_1) \cdot u_n - (\nu + \nu_r) \nabla u_n : \nabla \psi_1 \right] dx dt + \int_\Omega u_0 \cdot \psi_1(0, x) dx
\]
\[
+ \int_0^T \int_{\Omega} \left[ 2\nu_r w_n \cdot \text{curl} \psi_1 - \mu_0 \left( (m_n + h_n) \cdot \nabla \psi_1 \right) \cdot h_n \right] dx dt
\]
\[
\rightarrow_{n \to \infty} \int_0^T \int_{\Omega} \left[ u \cdot \partial_t \psi_1 + ((u \cdot \nabla) \psi_1) \cdot u - (\nu + \nu_r) \nabla u : \nabla \psi_1 \right] dx dt + \int_\Omega u_0 \cdot \psi_1(0, x) dx
\]
\[
+ \int_0^T \int_{\Omega} \left[ 2\nu_r w \cdot \text{curl} \psi_1 - \mu_0 \left( (m + h) \cdot \nabla \psi_1 \right) \cdot h \right] dx dt
\]
where we denoted by \( \left( (m + h) \cdot \nabla \psi_1 \right) \cdot h \) the weak limit of \( \left( (m_n + h_n) \cdot \nabla \psi_1 \right) \cdot h_n \),
\[
0 = \int_\Omega u_n(t, x) \cdot \nabla \psi_2(t, x) dx \rightarrow_{n \to \infty} \int_\Omega u(t, x) \cdot \nabla \psi_2(t, x) dx,
\]
\[
0 = \int_0^T \int_{\Omega} \left[ w_n \cdot \partial_t \psi_3 + ((u_n \cdot \nabla) \psi_3) \cdot w_n - c_1 \nabla w_n : \nabla \psi_3 - c_2 \text{div} w_n \text{ div} \psi_3 \right] dx dt
\]
\[
+ \int_0^T \int_{\Omega} \left[ -4\nu_r w_n \cdot \psi_3 + 2\nu_r u_n \cdot \text{curl} \psi_3 + \mu_0 (m_n \times h_n) \cdot \psi_3 \right] dx dt + \int_\Omega w_0 \cdot \psi_3(0, x) dx
\]
\[
\rightarrow_{n \to \infty} \int_0^T \int_{\Omega} \left[ w \cdot \partial_t \psi_3 + ((u \cdot \nabla) \psi_3) \cdot w - c_1 \nabla w : \nabla \psi_3 - c_2 \text{div} w \text{ div} \psi_3 \right] dx dt
\]
\[
+ \int_0^T \int_{\Omega} \left[ -4\nu_r w \cdot \psi_3 + 2\nu_r u \cdot \text{curl} \psi_3 + \mu_0 (m + h) \cdot \psi_3 \right] dx dt + \int_\Omega w_0 \cdot \psi_3(0, x) dx.
\]

Note that we denoted the weak limit of \( m_n \times h_n \) by \( \overrightarrow{m} \times \overrightarrow{h} \), and
\[
0 = \int_0^T \int_{\Omega} \left[ m_n \cdot \partial_t \psi_4 + (u_n \cdot \nabla) \psi_4 \cdot m_n - \sigma_n \text{curl} m_n \cdot \text{curl} \psi_4 - \sigma_n \text{div} m_n \text{ div} \psi_4 \right] dx dt
\]
\[
+ \int_\Omega m_0 \cdot \psi_4(0, x) dx + \int_0^T \int_{\Omega} \left[ (w_n \times m_n) \cdot \psi_4 - \frac{1}{\tau} (m_n - \kappa_0 h_n) \cdot \psi_4 \right] dx dt
\]
\[
\rightarrow_{n \to \infty} \int_0^T \int_{\Omega} \left[ m \cdot \partial_t \psi_4 + (u \cdot \nabla) \psi_4 \cdot m \right] dx dt + \int_\Omega m_0 \cdot \psi_4(0, x) dx
\]
\[
+ \int_0^T \int_{\Omega} \left[ (w \times m) \cdot \psi_4 - \frac{1}{\tau} (m - \kappa_0 h) \cdot \psi_4 \right] dx dt.
\]

Passing to the limit in the equation for \( \varphi_n, (3.4a) \), and the equation for \( h_n, h_n = \nabla \varphi_n \), we obtain that \( h = \nabla \varphi \) in \( L^2(\Omega) \) and that \( \varphi \) satisfies the equation
\[
\int_{\Omega} \nabla \varphi \cdot \nabla \psi dx = \int_{\Omega} h \cdot \nabla \psi dx = \int_{\Omega} (h_a - m) \cdot \nabla \psi dx
\]
for any test function \( \psi \in H^1(\Omega) \). In essence, to arrive at the conclusion that \( (u, w, m, h, \varphi) \) is a weak solution of (1.1), we need to show that the weak limits
\[
( (m + h) \cdot \nabla \psi_1 ) \cdot h = ( (m + h) \cdot \nabla ) \psi_1 \cdot h, \quad \text{and} \quad \overrightarrow{m} \times \overrightarrow{h} = m \times h,
\]
on \([0, T] \times \Omega\) in the sense of distribution. This can be achieved by showing that either a subsequence of \(\{m_n\}_{n \in \mathbb{N}}\) or \(\{h_n\}_{n \in \mathbb{N}}\) converges strongly in \(L^2([0, T] \times \Omega)\). We will show in the following that the sequence \(\{m_n\}_{n \in \mathbb{N}}\) converges strongly (which will imply that also \(\{h_n\}_{n \in \mathbb{N}}\) converges strongly in \(L^2\)).

First we notice that we can use \(\varphi\) as a test function in (3.17), since it is in \(L^\infty(0, T; H^1(\Omega))\). This yields

\[
\int_{\Omega} |\nabla \varphi|^2 dx = \int_{\Omega} |\xi|^2 dx = \int_{\Omega} (h_n - m) \cdot \nabla \varphi dx = \int_{\Omega} (h_n - m) \cdot h dx, \quad \text{a.e. } t. \tag{3.19}
\]

where we have substituted \(h\) for \(\varphi\). We can also use \(\varphi_n\) as a test function at the level of approximation (3.4a):

\[
\int_{\Omega} |\nabla \varphi_n|^2 dx = \int_{\Omega} |\xi|^2 dx = \int_{\Omega} (h_n - m_n) \cdot \nabla \varphi_n dx = \int_{\Omega} (h_n - m_n) \cdot h_n dx.
\]

Passing to the limit \(n \to \infty\) in this last expression, we get

\[
\int_{\Omega} |\nabla \varphi|^2 dx = \int_{\Omega} |\xi|^2 dx = \int_{\Omega} (h_n \cdot \nabla \varphi - m \cdot \nabla \varphi) dx = \int_{\Omega} (h_n \cdot h - m \cdot h) dx, \quad \text{a.e. } t \tag{3.20}
\]

where \(\nabla \varphi\) and \(|\xi|^2\) denote the weak limits of the sequences \(|\nabla \varphi_n|^2\) and \(|\xi|^2\) respectively. Combining (3.19) and (3.20), and rearranging (the terms containing \(\{n\}\) converge strongly in \(L^2\)), we get the expression

\[
\int_{\Omega} (|\xi|^2 + m \cdot h) dx = \int_{\Omega} (|\xi|^2 + m \cdot h) dx.
\]

This looks not very exciting at first sight, but we will see later how it is useful. Next, we note that from (3.9), we have,

\[
\frac{1}{2} \int_{\Omega} |m_n(t,x)|^2 dx \leq \frac{1}{2} \int_{\Omega} |m_0|^2 dx - \frac{1}{\tau} \int_0^t \int_{\Omega} (|m_n|^2 - \kappa_0 h_n \cdot m_n) dx ds.
\]

As \(n \to \infty\), this converges to

\[
\frac{1}{2} \int_{\Omega} |m(t,x)|^2 dx \leq \frac{1}{2} \int_{\Omega} |m_0|^2 dx - \frac{1}{\tau} \int_0^t \int_{\Omega} (|m|^2 - \kappa_0 \xi \cdot m) dx ds, \tag{3.22}
\]

where we denoted the weak limit of \(|m_n|^2\) by \(|m|^2\). By Lemma 3.5, the weak limit \(m\) satisfies

\[
\frac{1}{2} \int_{\Omega} |m(t,x)|^2 dx = \frac{1}{2} \int_{\Omega} |m_0|^2 dx - \frac{1}{\tau} \int_0^t \int_{\Omega} (|m|^2 - \kappa_0 \xi \cdot m) dx ds
\]

Subtracting this identity from (3.22), we get

\[
\frac{1}{2} \int_{\Omega} (|m(t,x)|^2 - |m(t,x)|^2) dx \leq -\frac{1}{\tau} \int_0^t \int_{\Omega} (|m|^2 - |m|^2 - \kappa_0 (\xi \cdot m - \xi \cdot m)) dx ds.
\]

We replace \(\xi \cdot m - \xi \cdot m\) using (3.21):

\[
\frac{1}{2} \int_{\Omega} (|m(t,x)|^2 - |m(t,x)|^2) dx \leq -\frac{1}{\tau} \int_0^t \int_{\Omega} (|m|^2 - |m|^2 + \kappa_0 (|\xi|^2 - |\xi|^2)) dx ds. \tag{3.23}
\]

By [19, Corollary 3.33],

\[
\int_G |v|^2 dx \leq \liminf_{n \to \infty} \int_G |v_n|^2 dx \leq \int_G |\xi|^2 dx, \quad \text{and } |v|^2 \leq |\xi|^2 \text{ a.e. on } G, \tag{3.24}
\]

\(v \in \{m, h\}, G \in \{\Omega, [0, T] \times \Omega\}\), therefore the left hand side of (3.23) is nonnegative while the right hand side is nonpositive. Hence we have

\[
\frac{1}{2} \int_{\Omega} (|m(t,x)|^2 - |m(t,x)|^2) dx = 0.
\]
Thus, by (3.24), \( |\mathbf{m}(t, x)|^2 = |\mathbf{m}(t, x)|^2 \) for almost every \((t, x) \in [0, T] \times \Omega\). By [9, Theorem 1.1.1 (iii)], this implies that \( \mathbf{m}_n \to \mathbf{m} \) strongly in \( L^2([0, T] \times \Omega) \). Using this in (3.21), we see that also
\[
\int_0^T \int_\Omega |\mathbf{h}|^2 dx dt = \int_0^T \int_\Omega |\mathbf{h}_n|^2 dx dt,
\]
and thus also \( \mathbf{h}_n \to \mathbf{h} \) strongly in \( L^2([0, T] \times \Omega) \). This allows us to conclude that (3.18) holds (and hence point (iii) in Definition 2.1). The energy inequality (2.1) follows from passing to the limit in the energy inequality for the approximations \( \{(\mathbf{u}_n, \mathbf{w}_n, \mathbf{m}_n, \mathbf{h}_n)\}_n \). The weak time continuity of \((\mathbf{u}, \mathbf{w}, \mathbf{m})\) follows from (3.15) combined with [30, Lemma 1.4, Chapter III]. To see that \( \mathbf{h} \) is weakly continuous in time, we first note that by elliptic regularity (see e.g. [10, Theorem 6.33]), since \( \phi_t \) solves \( \Delta \phi_t = -\text{div} \mathbf{m}_t \),
\[
\|\phi_t\|_{W^{s,p+1}} \leq C \|\mathbf{m}_t\|_{W^{p,s}},
\]
for some \( s < 0 \) and hence since \( \mathbf{h}_t = \nabla \phi_t \), we obtain
\[
\|\mathbf{h}_t\|_{W^{p,s}} \leq C \|\mathbf{m}_t\|_{W^{p,s}} \leq C,
\]
for some \( s < 0 \) small enough. This combined with \( \mathbf{h} \in L^\infty(0, T; L^2(\Omega)) \) yields \( \mathbf{h} \in C_w([0, T]; L^2(\Omega)) \) by [30, Lemma 1.4, Chapter III]. □

4. CONVERGENCE TO THE EQUILIBRIUM \( \tau \to 0 \)

We now proceed to proving Theorems 1.3 and 1.4. For convenience, we recall the statement of Theorem 1.3:

**Theorem 4.1.** Denote \( \mathcal{U}_\tau := (\mathbf{u}_\tau, \mathbf{w}_\tau, \mathbf{m}_\tau, \mathbf{h}_\tau) \), \( \mathbf{h}_\tau = \nabla \varphi_\tau \) the solution of system (1.1) for a given \( \tau > 0 \). Then as \( \tau \to 0 \), a subsequence of \( \{\mathcal{U}_\tau\}_{\tau > 0} \) converges in \( L^2([0, T] \times \Omega) \) to a weak solution of (1.10).

**Proof.** From the energy balance (2.1), we get that the \( \mathcal{U}_\tau = (\mathbf{u}_\tau, \mathbf{w}_\tau, \mathbf{m}_\tau, \mathbf{h}_\tau) \) satisfy the following uniform bounds for given \( \tau > 0 \), and fixed time horizon \( T > 0 \),
\[
\|\mathbf{u}_\tau\|_{L^\infty(0, T; L^2(\Omega))} + \|\mathbf{u}_\tau\|_{L^2(0, T; H^1(\Omega))} \leq C, \quad (4.1a)
\]
\[
\|\mathbf{w}_\tau\|_{L^\infty(0, T; L^2(\Omega))} + \|\mathbf{w}_\tau\|_{L^2(0, T; H^1(\Omega))} \leq C, \quad (4.1b)
\]
\[
\|\mathbf{h}_\tau\|_{L^\infty(0, T; L^2(\Omega))} \leq C, \quad (4.1c)
\]
\[
\|\varphi_\tau\|_{L^\infty(0, T; H^1(\Omega))} \leq C, \quad (4.1d)
\]
\[
\|\mathbf{m}_\tau\|_{L^\infty(0, T; L^2(\Omega))} \leq C, \quad (4.1e)
\]
\[
\tau^{-1/2} \|\mathbf{m}_\tau - \kappa_0 \mathbf{h}_\tau\|_{L^2((0, T) \times \Omega)} \leq C. \quad (4.1f)
\]

The first two bounds (4.1a) and (4.1b) combined with (3.15), imply using the Aubin-Lions lemma
\[
\mathbf{u}_\tau \to \mathbf{U}, \quad \mathbf{w}_\tau \to \mathbf{W}, \quad \text{in } L^p((0, T) \times \Omega), \quad 1 \leq p < 6,
\]
up to a subsequence, for some limiting functions \( \mathbf{U}, \mathbf{W} \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)) \). The third, forth and fifth bound (4.1c), (4.1d) and (4.1f), imply, using the Banach-Alaoglu theorem,
\[
\mathbf{m}_\tau \rightharpoonup^* \mathbf{M}, \quad \mathbf{h}_\tau \rightharpoonup^* \mathbf{H}, \quad \text{weak* in } L^\infty(0, T; L^2(\Omega)),
\]
\[
\varphi_\tau \rightharpoonup^* \Phi, \quad \text{weak* in } L^\infty(0, T; H^1(\Omega)), \quad (4.2)
\]
for limiting functions \( \mathbf{M}, \mathbf{H} \in L^\infty(0, T; L^2(\Omega)) \) and \( \Phi \in L^\infty(0, T; H^1(\Omega)) \). Moreover, \( \nabla \Phi = \mathbf{H} \) because \( \nabla \varphi_\tau = \mathbf{h}_\tau \) and both quantities converge weak*. Using the sixth a priori bound (4.1f) and combining it with the weak* convergence (4.2), we obtain for any test function \( \psi \in L^2([0, T] \times \Omega) \),
\[
\left| \int_0^T \int_\Omega (\kappa_0 \mathbf{H} - \mathbf{M}) \cdot \psi dx dt \right| = \lim_{\tau \to 0} \left| \int_0^T \int_\Omega (\kappa_0 \mathbf{h}_\tau - \mathbf{m}_\tau) \cdot \psi dx dt \right|
\]
\[
\leq \lim_{\tau \to 0} \|\kappa_0 \mathbf{h}_\tau - \mathbf{m}_\tau\|_{L^2} \|\psi\|_{L^2} \leq C \lim_{\tau \to 0} \tau^{1/2} = 0,
\]
hence \( \kappa_0 \mathbf{H} = \mathbf{M} \) in \( L^2([0, T] \times \Omega) \).
Using (4.2) to pass to the limit in the weak formulation of equation (1.1f), we get for test functions $ψ \in L^1(0,T;H^1(Ω))$
\[
\int_0^T \int Ω \left( h_\tau \cdot \nabla ψ \right) dx dt = \int_0^T \int Ω \left( h_\tau + m_\tau \right) \cdot \nabla ψ dx dt \rightarrow \int_0^T \int Ω \left( H + M \right) \cdot \nabla ψ dx dt,
\]

hence in the limit
\[
\int_0^T \int Ω \left( h_\tau \cdot \nabla ψ \right) dx dt = \int_0^T \int Ω \left( H + M \right) \cdot \nabla ψ dx dt,
\]
for any test function $ψ \in L^1(0,T;H^1(Ω))$. In particular, we can use $Φ$ as a test function and get (using $∇Φ = H$),
\[
\int_0^T \int Ω \left( h_\tau \cdot ∇Φ \right) dx dt = \int_0^T \int Ω \left( H + M \right) \cdot H dx dt = \int_0^T \int Ω \left( 1 + κ_0 \right) |H|^2 dx dt.
\]

On the other hand, we could choose $ψ = ϕ_τ$ as a test function in (4.3), and pass to the limit $τ \rightarrow 0$:
\[
\int_0^T \int Ω \left( h_\tau \cdot ∇ϕ_τ \right) dx dt \leftarrow \int_0^T \int Ω \left( h_\tau \cdot ∇ϕ_τ \right) dx dt = \int_0^T \int Ω \left( h_\tau + m_\tau \right) \cdot h_\tau dx dt \rightarrow \int_0^T \int Ω \left( H + M \right) \cdot H dx dt.
\]

where $\left( H + M \right) \cdot H$ is the weak limit of $(h_\tau + m_\tau) \cdot h_\tau$. Combining (4.4) and (4.5), we get
\[
\int_0^T \int Ω \left( H + M \right) \cdot H dx dt = \lim_{τ \rightarrow 0} \int_0^T \int Ω \left( h_\tau + m_\tau \right) \cdot h_\tau dx dt = \int_0^T \int Ω \left( 1 + κ_0 \right) |H|^2 dx dt,
\]

Note that
\[
(1 + κ_0) \| h_\tau \|_{L^2((0,T)×Ω)}^2 = \int_0^T \int Ω \left( |h_\tau|^2 + h_\tau \cdot m_\tau \right) dx dt + \int_0^T \int Ω \left( h_\tau (κ_0 h_\tau - m_\tau) \right) dx dt,
\]

therefore
\[
\left| (1 + κ_0) \| h_\tau \|_{L^2((0,T)×Ω)}^2 - \int_0^T \int Ω \left( |h_\tau|^2 + h_\tau \cdot m_\tau \right) dx dt \right| = \left| \int_0^T \int Ω \left( h_\tau (κ_0 h_\tau - m_\tau) \right) dx dt \right| \leq \| h_\tau \|_{L^2} \| m_\tau - κ_0 h_\tau \|_{L^2} \leq C \sqrt{τ},
\]

and
\[
(1 + κ_0) \lim_{τ \rightarrow 0} \| h_\tau \|_{L^2((0,T)×Ω)}^2 - \int_0^T \int Ω \left( H \cdot (H + M) \right) dx dt
\]
\[
= (1 + κ_0) \lim_{τ \rightarrow 0} \int_0^T \int Ω \left( |h_\tau|^2 \right) dx dt - \lim_{τ \rightarrow 0} \int_0^T \int Ω \left( h_\tau \cdot (h_\tau + m_\tau) \right) dx dt
\]
\[
= \lim_{τ \rightarrow 0} \int_0^T \int Ω \left( h_\tau \cdot (κ_0 h_\tau - m_\tau) \right) dx dt
\]
\[
\leq \lim sup_{τ \rightarrow 0} \int_0^T \int Ω \left( h_\tau \cdot (κ_0 h_\tau - m_\tau) \right) dx dt
\]
\[
\leq \lim sup_{τ \rightarrow 0} \int_0^T \int Ω \left( |h_\tau|^2 \right) \left( |κ_0 h_\tau - m_\tau| \right) dx dt
\]
\[
\leq C \lim sup_{τ \rightarrow 0} \sqrt{τ} = 0.
\]

So combining this with (4.6), we get
\[
\lim_{τ \rightarrow 0} \| h_\tau \|_{L^2((0,T)×Ω)}^2 = \int_0^T \int Ω |H|^2 dx dt.
\]

Hence
\[
\lim_{τ \rightarrow 0} \| h_\tau - H \|_{L^2}^2 = \lim_{τ \rightarrow 0} \| h_\tau \|_{L^2}^2 - 2 \lim_{τ \rightarrow 0} \int_0^T \int Ω h_\tau \cdot H dx dt + \| H \|_{L^2}^2
\]
the last equality follows from the weak convergence of \( \{ h_\tau \}_{\tau > 0} \). Therefore a subsequence of \( \{ h_\tau \}_{\tau > 0} \) converges in fact strongly in \( L^2 \). Using this and the a priori bound \((4.1f)\), we also get strong convergence of a subsequence of \( \{ m_\tau \}_{\tau > 0} \):

\[
\lim_{\tau \to 0} \| m_\tau - \kappa_0 H \|_{L^2} \leq \lim_{\tau \to 0} \| m_\tau - \kappa_0 h_\tau \|_{L^2} + \lim_{\tau \to 0} \| \kappa_0 h_\tau - \kappa_0 H \|_{L^2} = 0.
\]

This allows us to pass to the limit in all the terms in the weak formulation of \((1.1)\) and obtain that a subsequence converges, as \( \tau \to 0 \), to a weak solution of \((1.10)\). For the last term in \((1.1a)\), we use Lemma 2.3. In equation \((1.1d)\), we multiply everything by \( \tau \) before passing \( \tau \to 0 \) in the weak formulation.

\[\square\]

### 4.1. Convergence when the solution of the limiting system is smooth

When the solution of the limiting system \((1.10)\) is smooth, which is the case for short times and smooth data and in two space dimensions for smooth enough data (this is shown in Appendix A), one can show a convergence rate in \( \tau \) for the approximate solutions of \((1.1)\):

**Theorem 4.2.** If the solution of \((1.10)\) satisfies \( U, W \in L^\infty(0, T; \text{Lip}(\Omega)) \), \( H = \nabla \Phi \in L^2(0, T; H^1(\Omega)) \), \( \partial_t H \in L^2([0, T] \times \Omega) \); and the initial data for \((1.1)\) and \((1.10)\) satisfy

\[
\| u_0 - U_0 \|^2_{L^2(\Omega)} + \| w_0 - W_0 \|^2_{L^2(\Omega)} + \| m_0 - M_0 \|^2_{L^2(\Omega)} \leq C \tau,
\]

then the solutions \( U_\tau \) of \((1.1)\) converge as \( \tau \to 0 \) to the solution of the limiting system \((1.10)\) at the rate:

\[
\begin{align*}
\| u_\tau - U \|^2_{L^2(\Omega)}(t) + \| w_\tau - W \|^2_{L^2(\Omega)}(t) + \| m_\tau - M \|^2_{L^2(\Omega)}(t) \\
+ \| h_\tau - H \|^2_{L^2(\Omega)}(t) + \| \nabla (u_\tau - U) \|^2_{L^2([0, T] \times \Omega)} + \| \nabla (w_\tau - W) \|^2_{L^2([0, T] \times \Omega)} & \leq C \sqrt{\tau} (1 + \exp(Ct)).
\end{align*}
\]

**Proof.** To prove this theorem, we will use the relative entropy method that was introduced by Dafermos \([5, 6]\) and DiPerna \([7]\) in the context of hyperbolic systems of conservation laws, see also \([4]\). To this end, we define the following relative entropy functional,

\[
E(U_\tau, U_0) := E(U_\tau) - E(U_0) - dE(U_0)(U_\tau - U_0),
\]

where the energy \( E \) is defined in \((2.2)\). The integral of \( E(U_\tau, U_0) \) over \( \Omega \) measures the distance in \( L^2 \) of the solution \( U_\tau := (u_\tau, w_\tau, m_\tau, h_\tau) \) of \((1.1)\) from the solution \( U_0 := (U, W, M, H) \) of the limiting system \((1.10)\). For notational convenience, we will omit writing the dependence of \( u_\tau, w_\tau, m_\tau \) and \( h_\tau \) on \( \tau \) and write \( U_\tau := (u, w, m, h) \), while we denote the solution of the limiting system by \( U_0 := (U, W, M, H) \). \( dE(U_0) \) is the derivative of \( E \) with respect to all variables, that is, \( dE(U_0) = (U, W, \frac{\mu_0}{\kappa_0} M, \mu_0 H) \). Some basic algebra shows that \( E(U_\tau, U_0) \) can be written as

\[
E(U_\tau, U_0) = \frac{1}{2} \left( \| u - U \|^2 + \| w - W \|^2 + \| m - M \|^2 + \mu_0 \| h - H \|^2 \right),
\]

or

\[
E(U_\tau, U_0) := E(U_\tau) + E(U_0) - dE(U_0)U_\tau,
\]

From the energy (in)equality \((2.1)\) and Remark 2.2, we obtain

\[
\int_\Omega (E(U_\tau(t)) + E(U_0(t))) \, dx + \int_0^t \int_\Omega (D(U_\tau) + D(U_0)) \, dx \, ds \\
\leq \int_\Omega (E(U_\tau(0)) + E(U_0(0))) \, dx + \mu_0 \int_0^t \int_\Omega \delta_t h_\omega(H + h) \, dx \, ds.
\]

Then we note that, since \( U_\tau \in C_w([0, T]; L^2(\Omega)) \)

\[
\int_\Omega dE(U_0(t))U_\tau(t) \, dx - \int_\Omega dE(U_0(\eta))U_\tau(\eta) \, dx = - \lim_{\varepsilon \to 0} \int_0^T \int_\Omega dE(U_0(s))U_\tau(s) \partial_s \theta_\varepsilon(s) \, dx \, ds,
\]
where \( \theta_\varepsilon = 1_{[\eta, t]} * \omega_\varepsilon \) is a regularized version of the indicator function of the interval \([\eta, t]\), where \( \eta \geq \varepsilon > 0 \) is a small number, \( \omega_\varepsilon(s) := \frac{1}{\varepsilon} \omega(s/\varepsilon) \) is a symmetric, nonnegative, smooth, compactly supported on \([-1, 1]\) mollifier with \( \int \omega(s)ds = 1 \). Hence, we can compute an expression for \( \int_0^T \int_\Omega dE(U_0(s)) \| \mathcal{U}_\varepsilon(s) \| \partial_s \theta_\varepsilon(s) dxds \) using the weak formulations of the equations for \( \mathcal{U}_\varepsilon \), see Definition 2.1, points (ii) and (iii), and the strong formulation (1.10) for \( U_0 \) since it is assumed to be sufficiently regular. We have

\[
\int_0^T \int_\Omega dE(U_0(s)) \| \mathcal{U}_\varepsilon(s) \| \partial_s \theta_\varepsilon(s) dxds = \int_0^T \int_\Omega \left( Uw + \frac{\mu_0}{\kappa_0} Mm + \kappa_0 Hh \right) \partial_s \theta_\varepsilon(s) dxds
\]

Finally, using (1.1a) and (1.10a), we compute:

\[
(a) = \int_0^T \int_\Omega \left[ 2 \nu \nabla u : \nabla U + 2 \nu_\varepsilon (\text{curl} \ u \text{curl} U - \text{curl} Uw - \text{curl} uW) \right] \theta_\varepsilon dxds
\]

\[
+ \mu_0 \int_0^T \int_\Omega h[(m + h) \cdot \nabla]U \theta_\varepsilon dxds
\]

\[
+ \int_0^T \int_\Omega (u - U)[(U - u) \cdot \nabla]U \theta_\varepsilon dxds.
\]

Equations (1.1c) and (1.10c) yield:

\[
(b) = \int_0^T \int_\Omega \left[ 2c_1 \nabla w : \nabla W + 2c_2 \text{div} W \text{div} w + 8\nu_\varepsilon wW - 2 \nu_\varepsilon (\text{curl} Uw + \text{curl} uW) \right] \theta_\varepsilon dxds
\]

\[
- \mu_0 \int_0^T \int_\Omega (m \times h) \cdot \nabla \theta_\varepsilon dxds + \int_0^T \int_\Omega (w - W)[(U - u) \cdot \nabla]W \theta_\varepsilon dxds.
\]

From (1.1d) and (1.10d), we obtain

\[
(c) = \frac{\mu_0}{\kappa_0} \int_0^T \int_\Omega \left[ -m(u \cdot \nabla)M - (w \times m) \cdot M + \frac{1}{\tau}(m - \kappa_0 h)M \right] \theta_\varepsilon dxds
\]

\[
- \mu_0 \int_0^T \int_\Omega Hm \theta_\varepsilon dxds.
\]

Finally, using (1.1e), (1.1f), (1.10e) and (1.10f), we get,

\[
(d) = -\mu_0 \int_0^T \int_\Omega \partial_s h_m(h + H) \theta_\varepsilon dxds + \mu_0 \int_0^T \int_\Omega m(u \cdot \nabla)H \theta_\varepsilon dxds
\]

\[
+ \mu_0 \int_0^T \int_\Omega hM \theta_\varepsilon dxds - \frac{\mu_0}{\tau} \int_0^T \int_\Omega (m - \kappa_0 h)H \theta_\varepsilon dxds + \mu_0 \int_0^T \int_\Omega (w \times m) \cdot H \theta_\varepsilon dxds
\]
Combining (a) – (d), sending $\varepsilon \to 0$ and using $M = \kappa_0 H$ (equation (1.10d)), we obtain

$$\int (dE(U(t))U_r(t) - dE(U_0)U_r(\eta))dx = -2 \int_\eta^t \int_\Omega [\nu \nabla u \cdot \nabla U + c_1 \nabla w : \nabla W + c_2 \nabla \cdot \nabla W \div w] dxds$$

$$- \nu_r \int_\eta^t \int_\Omega (2 \nabla u \cdot \nabla U - 4 \nabla Uw - 4 \nabla uW + 8wW) dxds$$

$$- \mu_0 \int_\eta^t \int_\Omega h[(m + h) \cdot \nabla]U dxds$$

$$- \int_\eta^t \int_\Omega (u - U)[(U - u) \cdot \nabla]U dxds$$

$$- \int_\eta^t \int_\Omega (w - W)[(U - u) \cdot \nabla]W dxds$$

$$+ \mu_0 \int_\eta^t \int_\Omega (m \times h) \cdot W dxds + \mu_0 \int_\eta^t \int_\Omega H_s(m - \kappa_0 h) dxds$$

$$+ \mu_0 \int_\eta^t \int_\Omega \partial_s h_s(h + H) dxds.$$  

(4.11)

This holds for any $\eta > 0$. Using the weak continuity of $U_r$ and $U_0$ and the integrability properties, we can pass $\eta \to 0$. Subtracting the result from (4.10), we get

$$\int E(U_r|U_0)(t)dx + \int_0^t \int_\Omega \nu |\nabla (u - U)|^2 dxds + \frac{\mu_0}{\kappa_0 T} \int_0^t \int_\Omega |m - \kappa_0 h|^2 dxds$$

$$+ \int_\Omega \int_0^t \int_\Omega (c_1 |\nabla (w - W)|^2 + c_2 |\nabla (w - W)|^2 + \nu_r |2(w - W) - \nabla (u - U)|^2) dxds$$

$$\leq \int E(U_r|U_0)(0)dx - \mu_0 \int_\Omega \int_0^t H_s(m - \kappa_0 h) dxds$$

$$+ \mu_0 \int_\Omega \int_0^t h[(m + h) \cdot \nabla]U dxds - \mu_0 \int_0^t \int_\Omega (m \times h) \cdot W dxds.$$

Let us denote

$$\mathcal{D}(U_r|U_0) := \nu |\nabla (u - U)|^2 + \frac{\mu_0}{\kappa_0 T} |m - \kappa_0 h|^2 + c_1 |\nabla (w - W)|^2$$

$$+ c_2 |\nabla (w - W)|^2 + \nu_r |2(w - W) - \nabla (u - U)|^2.$$

Then the previous identity becomes

$$\int E(U_r|U_0)(t)dx + \int_0^t \int \mathcal{D}(U_r|U_0)(s)dxds$$

$$\leq \int E(U_r|U_0)(0)dx + \int_0^t \int_\Omega (u - U)[(U - u) \cdot \nabla]U dxds$$

$$+ \mu_0 \int_\Omega \int_0^t H_s(m - \kappa_0 h) dxds$$

$$+ \mu_0 \int_\Omega \int_0^t h[(m + h) \cdot \nabla]U dxds - \mu_0 \int_0^t \int_\Omega (m \times h) \cdot W dxds.$$  

(4.12)
We start by bounding the terms $I_1$ and $I_2$.

$$|I_1| \leq \int_0^t \int_{\Omega} |u - U|^2 |\nabla U| \,dx\,ds \leq \|\nabla U\|_{L^\infty}^2 \|u - U\|_{L^2([0,t] \times \Omega)}^2,$$

and

$$|I_2| \leq \int_0^t \int_{\Omega} |u - U| |w - W| |\nabla W| \,dx\,ds \leq \|\nabla W\|_{L^\infty} \|u - U\|_{L^2([0,t] \times \Omega)} \|w - W\|_{L^2([0,t] \times \Omega)}$$

$$\leq \frac{1}{2} \|\nabla W\|_{L^\infty} \left( \|u - U\|_{L^2([0,t] \times \Omega)}^2 + \|w - W\|_{L^2([0,t] \times \Omega)}^2 \right).$$

Using Young’s inequality and the regularity of the limit functions $(U, W, H)$, we bound term $II$ as follows (notice that it indeed follows that $H_t \in L^2(\Omega)$ as long as $\partial_t h_{\sigma} \in L^2(\Omega)$):

$$|II| \leq \mu_0 \int_0^t \int_{\Omega} |m - \kappa_0 h| |H_s| \,dx\,ds$$

$$\leq \frac{\mu_0}{8\kappa_0 \tau} \int_0^t \int_{\Omega} |m - \kappa_0 h|^2 \,dx\,ds + 4\tau \mu_0 \kappa_0 \int_0^t \int_{\Omega} |H_s|^2 \,dx\,ds.$$

The second term on the right hand side is of order $C\tau$ since $H_t \in L^2(\Omega)$.

Assuming for the moment that all the involved functions are smooth, we rewrite term $III$ as follows (the general case follows by approximation, for example one can mollify all the variables and because the magnetostatic equation (1.1f)/(1.10f) is linear, the mollified variables solve a mollified equation):

$$III = \mu_0 \int_0^t \int_{\Omega} (h \cdot (m + h) \cdot \nabla) U \,dx\,ds$$

$$= \mu_0 \int_0^t \int_{\Omega} \left[ h \cdot (\kappa_0 h) \cdot \nabla U \right] \,dx\,ds$$

$$= \mu_0 \int_0^t \int_{\Omega} (h - H) \cdot \left[ (m - \kappa_0 h) \cdot \nabla U \right] \,dx\,ds$$

$$+ \mu_0 (1 + \kappa_0) \int_0^t \int_{\Omega} (h \cdot \nabla)(Uh) \,dx\,ds$$

$$= \mu_0 \int_0^t \int_{\Omega} (h - H) \cdot \left[ (m - \kappa_0 h) \cdot \nabla U \right] \,dx\,ds - \mu_0 \int_0^t \int_{\Omega} (m - \kappa_0 h) \cdot \nabla H \,dx\,ds$$

$$+ \mu_0 (1 + \kappa_0) \int_0^t \int_{\Omega} (h \cdot \nabla)(Uh) \,dx\,ds$$

$$= \mu_0 \int_0^t \int_{\Omega} (h - H) \cdot \left[ (m - \kappa_0 h) \cdot \nabla U \right] \,dx\,ds - \mu_0 \int_0^t \int_{\Omega} (m - \kappa_0 h) \cdot \nabla H \,dx\,ds$$

$$+ \mu_0 (1 + \kappa_0) \int_0^t \int_{\Omega} (h \cdot \nabla)(Uh) \,dx\,ds$$

$$= \mu_0 \int_0^t \int_{\Omega} (h - H) \cdot \left[ (m - \kappa_0 h) \cdot \nabla U \right] \,dx\,ds - \mu_0 \int_0^t \int_{\Omega} (m - \kappa_0 h) \cdot \nabla H \,dx\,ds$$

$$+ \mu_0 (1 + \kappa_0) \int_0^t \int_{\Omega} (h \cdot \nabla)(Uh) \,dx\,ds$$
where we also used in the third equality that, since \( h = \nabla \varphi \) and \( \text{div} \, U = 0 \),

\[
\int_{\Omega} U \cdot (h \cdot \nabla)h \, dx = \int_{\Omega} U \cdot ((\nabla \varphi) \nabla \varphi) \, dx = \sum_{i,j=1}^{3} U^{(i)} \partial_j \varphi \partial_i \varphi \, dx
\]

\[
= \frac{1}{2} \sum_{i,j=1}^{3} U^{(i)} \partial_i \varphi \partial_j \varphi^2 \, dx = -\int_{\Omega} \text{div} \, U |\nabla \varphi|^2 \, dx = 0. 
\]

and equation (1.10f) in the second last equality, and (4.13) with \( h \) replaced by \( (h - H) \) in the last equality. Hence

\[
\text{III} = \mu_0 \int_{0}^{t} \int_{\Omega} h \left( (m + h) \cdot \nabla \right) U \, dx \, ds
\]

\[
= \mu_0 \int_{0}^{t} \int_{\Omega} (h - H) \cdot \left( (m - \kappa_0 h) \cdot \nabla \right) U \, dx \, ds - \mu_0 \int_{0}^{t} \int_{\Omega} U \cdot \left( (m - \kappa_0 h) \cdot \nabla \right) H \, dx \, ds
\]

\[
+ \mu_0 (1 + \kappa_0) \int_{0}^{t} \int_{\Omega} (h - H) \cdot \left( (h - H) \cdot \nabla \right) U \, dx \, ds
\]

(4.14)

We observe that in this last identity (4.14) all terms are bounded when \( h, m \in L^2([0,t] \times \Omega) \) and \( U, H \in L^\infty(0,T; \text{Lip}(\Omega)) \) and hence it holds in our situation by approximation of all quantities with smooth functions. We continue to bound the terms \( \text{III}_1, \text{III}_2 \) and \( \text{III}_3 \): For the first term, \( \text{III}_1 \), we use Young’s inequality and then Hölder’s inequality:

\[
|\text{III}_1| \leq \frac{\mu_0}{8 \kappa_0 \tau} \int_{0}^{t} \int_{\Omega} |m - \kappa_0 h|^2 \, dx \, ds + 2 \mu_0 \kappa_0 \tau \|\nabla U\|^2_{L^\infty} \int_{0}^{t} \int_{\Omega} |h - H|^2 \, dx \, ds.
\]

Using Young’s inequality, we also bound the second term, \( \text{III}_2 \) by

\[
|\text{III}_2| \leq \frac{\mu_0}{8 \kappa_0 \tau} \int_{0}^{t} \int_{\Omega} |m - \kappa_0 h|^2 \, dx \, ds + 2 \tau \mu_0 \kappa_0 \int_{0}^{t} \int_{\Omega} |U|^2 |\nabla H|^2 \, dx \, ds.
\]

For the third term, we use again Hölder’s inequality

\[
|\text{III}_3| \leq \mu_0 (1 + \kappa_0) \|\nabla U\|_{L^\infty} \int_{0}^{t} \int_{\Omega} |h - H|^2 \, dx \, ds.
\]

Combining the three, we get

\[
|\text{III}| \leq \frac{\mu_0}{4 \kappa_0 \tau} \int_{0}^{t} \int_{\Omega} |m - \kappa_0 h|^2 \, dx \, ds + 2 \tau \mu_0 \kappa_0 \int_{0}^{t} \int_{\Omega} |U|^2 |\nabla H|^2 \, dx \, ds
\]

\[
+ \mu_0 \|\nabla U\|_{L^\infty} (2 \kappa_0 \tau \|\nabla U\|_{L^\infty} + 1 + \kappa_0) \int_{0}^{t} \int_{\Omega} |h - H|^2 \, dx \, ds. \quad (4.15)
\]

To bound term IV, we note that since \( h \times h = 0 \), we can rewrite it as

\[
\text{IV} = -\mu_0 \int_{0}^{t} \int_{\Omega} W \cdot ((m - \kappa_0 h) \times h) \, dx \, ds.
\]

Using Hölder and Young’s inequality, we can bound it as follows:

\[
|\text{IV}| \leq \mu_0 \|W\|_{L^\infty} \|m - \kappa_0 h\|_{L^2([0,t] \times \Omega)} \|h\|_{L^2([0,t] \times \Omega)}
\]

\[
\leq \frac{\mu_0}{8 \tau \kappa_0} \|m - \kappa_0 h\|^2_{L^2([0,t] \times \Omega)} + 2 \mu_0 \tau \kappa_0 \|h\|^2_{L^2([0,t] \times \Omega)} \|W\|^2_{L^\infty}.
\]
Thus, under the assumption that \( \mathbf{U}, \mathbf{W} \in L^\infty(0, T; \text{Lip}(\Omega)) \) and \( \mathbf{H} \in L^2(0, T; H^1(\Omega)), \partial_t \mathbf{H} \in L^2([0, T] \times \Omega) \), the evolution of the relative entropy, (4.12), is bounded as follows:

\[
\int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(t)dx + \int_0^t \int_\Omega \mathcal{D}(\mathcal{U}_t|\mathcal{U}_0)(s)dxds \\
\leq \int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(0)dx + C \int_0^t \int_\Omega |\mathbf{u} - \mathbf{U}|^2 dxds + C \int_0^t \int_\Omega |\mathbf{w} - \mathbf{W}|^2 dxds \\
+ C \int_0^t \int_\Omega |\mathbf{h} - \mathbf{H}|^2 dxds + \frac{\mu_0}{2\kappa_0^2} \int_0^t \int_\Omega |\mathbf{m} - \kappa_0 \mathbf{h}|^2 dxds + C\tau. \quad (4.16)
\]

Defining \( \tilde{\mathcal{D}}(\mathcal{U}_t|\mathcal{U}_0) \) by

\[
\tilde{\mathcal{D}}(\mathcal{U}_t|\mathcal{U}_0) := \nu |\nabla(\mathbf{u} - \mathbf{U})|^2 + \frac{\mu_0}{2\kappa_0^2} |\mathbf{m} - \kappa_0 \mathbf{h}|^2 + c_1 |\nabla(\mathbf{w} - \mathbf{W})|^2 \\
+ c_2 |\text{div}(\mathbf{w} - \mathbf{W})|^2 + \nu_r |2(\mathbf{w} - \mathbf{W}) - \text{curl}(\mathbf{u} - \mathbf{U})|^2,
\]

this becomes

\[
\int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(t)dx + \int_0^t \int_\Omega \tilde{\mathcal{D}}(\mathcal{U}_t|\mathcal{U}_0)(s)dxds \\
\leq \int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(0)dx + C \int_0^t \int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(s)dxds + C\tau. \quad (4.17)
\]

Now using Grönwall’s inequality for \( A(t) := \int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(t)dx \), we obtain

\[
\int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(t)dx \leq \left( \int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(0)dx + C\tau \right) \exp(C\tau).
\]

Using this in (4.17), we can also bound \( \tilde{\mathcal{D}}(\mathcal{U}_t|\mathcal{U}_0) \):

\[
\int_0^t \int_\Omega \tilde{\mathcal{D}}(\mathcal{U}_t|\mathcal{U}_0)(s)dxds \leq \left( \int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(0)dx + C\tau \right) (C + \exp(C\tau)).
\]

Therefore, if the initial data satisfy

\[
\|\mathbf{u}_0 - \mathbf{U}_0\|^2_{L^2(\Omega)} + \|\mathbf{w}_0 - \mathbf{W}_0\|^2_{L^2(\Omega)} + \|\mathbf{m}_0 - \mathbf{M}_0\|^2_{L^2(\Omega)} \leq C\tau,
\]

then, since

\[
\Delta(\varphi_0 - \Phi_0) = -\text{div}(\mathbf{m}_0 - \mathbf{M}_0),
\]

and hence by the Lax-Milgram theorem,

\[
\|\mathbf{h}_0 - \mathbf{H}_0\|^2_{L^2(\Omega)} = \|\nabla \varphi_0 - \nabla \Phi_0\|^2_{L^2(\Omega)} \leq \|\mathbf{m}_0 - \mathbf{M}_0\|^2_{L^2(\Omega)} \leq C\sqrt{\tau},
\]

we have that

\[
\int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(0)dx \leq C\tau.
\]

Therefore

\[
\int_\Omega \mathcal{E}(\mathcal{U}_t|\mathcal{U}_0)(t)dx + \int_0^t \int_\Omega \tilde{\mathcal{D}}(\mathcal{U}_t|\mathcal{U}_0)(s)dxds \leq C\tau(1 + \exp(C\tau)),
\]

which proves Theorem 1.4.

\[\square\]

Appendix A. Regular solutions of limiting system in 2D

The goal of this section is to apply the arguments from the proof of regularity and uniqueness of the 2D Navier-Stokes equations, see for example [30], to system (1.10) to show it has a unique regular solution if the spatial dimension is 2 and the initial data and \( f \) are sufficiently smooth. First we notice that from (1.10d), equations (1.10e)–(1.10f) become

\[
\Delta \Phi(t, x) = 0, \quad (t, x) \in [0, T] \times \Omega; \quad \frac{\partial \Phi}{\partial n} = \frac{1}{1 + \kappa_0} h_n \cdot n, \quad (t, x) \in [0, T] \times \partial \Omega; \quad \int_{\Omega} \Phi \, dx = 0,
\]

and so \( \Phi \) is completely decoupled from \( U \) and \( W \). Hence if \( h_n \) and the domain are sufficiently smooth, then by the trace theorem (see e.g. [16, Thm 2.5.3]) and elliptic regularity, the unique \( \Phi \) is also smooth. Moreover, the source term in (1.10a) can be rewritten as

\[
\mu_0 (M \cdot \nabla) H = \frac{\mu_0 \kappa_0}{2} \nabla \left( |H|^2 \right),
\]

and added to the pressure. Hence it remains to show that the solution \((U, W)\) of the system

\[
U_t + (U \cdot \nabla) U - (\nu + \nu_r) \Delta U + \nabla \bar{P} = 2\nu_r \text{curl} W, \quad (A.1a)
\]

\[
\text{div} U = 0, \quad (A.1b)
\]

\[
W_t + (U \cdot \nabla) W - c_1 \Delta W - c_2 \text{div} W + 4\nu_r W = 2\nu_r \text{curl} U, \quad (A.1c)
\]

where \( \bar{P} = P - \frac{2}{\mu_0 \kappa_0} |H|^2 \), is regular, which is very similar to showing regularity and uniqueness of the 2D Navier-Stokes equations. We add an outline of the proof here for completeness and because there is some coupling between the two equations involved.

Theorem A.1 (Uniqueness of solutions in 2d). Let the spatial dimension \( d = 2 \). Then the solution \((U, W)\) of (A.1) with initial data \( U_0 \in L^2_{\text{div}}(\Omega) \) and \( W_0 \in L^2(\Omega) \) is unique and continuous as a function from \([0, T]\) into \( L^2(\Omega)\).

Proof. The regularity follows as in the proof of [30, Theorem III.3.2]: From the equations (A.1) and Lemma III.3.4 in [30], it follows that \( \partial_t U, \partial_t W \in L^2(0, T; H^{-1}(\Omega)) \). Then [30, Lemma III.1.2] implies that \( U \) and \( W \) are almost everywhere equal to continuous functions from \([0, T]\) to \( L^2_{\text{div}}(\Omega) \) and \( L^2(\Omega) \) respectively, that is, \( U \in C([0, T]; L^2_{\text{div}}(\Omega)) \), \( W \in C([0, T]; L^2(\Omega)) \). Moreover,

\[
\frac{d}{dt} \|U(t)\|^2_{L^2} = 2 \langle \partial_t U, U \rangle, \quad \frac{d}{dt} \|W(t)\|^2_{L^2} = 2 \langle \partial_t W, W \rangle, \quad (A.2)
\]

where \( \langle \cdot, \cdot \rangle \) denotes the duality pairing between \( H_0^1 \) and its dual \( H^{-1} \). We assume that \((U_1, W_1)\) and \((U_2, W_2)\) are two solutions of (A.1). Then the difference \((U, W) := (U_1 - U_2, W_1 - W_2)\) satisfies

\[
U_t + (U_1 \cdot \nabla) U_1 - (U_2 \cdot \nabla) U_2 - (\nu + \nu_r) \Delta U + \nabla P = 2\nu_r \text{curl} W, \quad \text{div} U = 0, \quad (A.3)
\]

\[
W_t + (U_1 \cdot \nabla) W_1 - (U_2 \cdot \nabla) W_2 - c_1 \Delta W - c_2 \text{div} W + 4\nu_r W = 2\nu_r \text{curl} U,
\]

with initial condition \( U(0, \cdot) = 0 \) and \( W(0, \cdot) = 0 \) and \( P := \bar{P}_1 - \bar{P}_2 \). We take the a.e. in \( t \) the inner product of these equations with \( U \) and \( W \) respectively and use (A.2) to obtain

\[
\frac{d}{dt} \left( \|U(t)\|^2_{L^2} + \|W(t)\|^2_{L^2} \right) + 2\nu \|\nabla U\|^2_{L^2} + 2c_1 \|
abla W\|^2_{L^2} + 2c_2 \|	ext{div} W\|^2_{L^2} + 2\nu_r \|\text{curl} U - 2W\|^2_{L^2}
\]

\[
= 2 \int_{\Omega} [(U_1 \cdot \nabla) U_1 - (U_2 \cdot \nabla) U_2] \cdot U \, dx - 2 \int_{\Omega} [(U_1 \cdot \nabla) W_1 - (U_2 \cdot \nabla) W_2] \cdot W \, dx
\]

\[
= -2 \int_{\Omega} [(U_1 \cdot \nabla) U_2] \cdot U \, dx - 2 \int_{\Omega} [(U_1 \cdot \nabla) W_2] \cdot W \, dx.
\]

We bound the two terms on the right hand side using Ladyshenskaya’s inequality (see e.g. Lemma III.3.3 in [30]) and Young’s inequality:

\[
\left| 2 \int_{\Omega} [(U_1 \cdot \nabla) U_2] \cdot U \, dx \right| \leq C \|U\|^2_{L^4} \|
abla U_2\|^2_{L^2}
\]
\[
\leq C \|U\|_{L^2} \|
abla U\|_{L^2} \|
abla U_2\|_{L^2}
\]

\[
\leq \frac{\nu}{2} \|
abla U\|_{L^2}^2 + \frac{C}{\nu} \|U\|_{L^2}^2 \|
abla U_2\|_{L^2}^2 .
\]

Similarly,
\[
\left| 2 \int_{\Omega} [(U \cdot \nabla)W_2] \cdot W \, dx \right| \leq C \|W\|_{L^4} \|U\|_{L^4} \|
abla W_2\|_{L^2}
\]
\[
\leq C \|U\|_{L^2}^{1/2} \|
abla U\|_{L^2}^{1/2} \|W\|_{L^2}^{1/2} \|
abla W_2\|_{L^2}^{1/2} \|
abla W_2\|_{L^2}
\]
\[
\leq \frac{\nu}{2} \|
abla U\|_{L^2}^2 + \frac{C}{\nu} \|U\|_{L^2}^2 \|
abla W_2\|_{L^2}^2 + c_1 \|
abla W_2\|_{L^2}^2 + \frac{C}{c_1} \|W\|_{L^2}^2 \|
abla W_2\|_{L^2}^2 ,
\]

and hence
\[
\frac{d}{dt} \left( \|U(t)\|_{L^2}^2 + \|W(t)\|_{L^2}^2 \right) + \nu \|
abla U\|_{L^2}^2 + c_1 \|
abla W_2\|_{L^2}^2 + 2c_2 \|\text{div } W\|_{L^2}^2 + 2\nu \|\text{curl } U - 2W\|_{L^2}^2
\]
\[
\leq \frac{C}{\nu} \|U\|_{L^2}^2 \left( \|
abla U_2\|_{L^2} + \|
abla W_2\|_{L^2}^2 \right) + \frac{C}{c_1} \|W\|_{L^2}^2 \|
abla W_2\|_{L^2}^2 .
\]

Using that \(\|
abla U_2\|_{L^2}^2, \|
abla W_2\|_{L^2}^2 \in L^1([0, T])\) and then applying Grönwall’s inequality, we obtain
\[
\|U(t)\|_{L^2}^2 + \|W(t)\|_{L^2}^2 \leq \left( \|U(0)\|_{L^2}^2 + \|W(0)\|_{L^2}^2 \right) \exp \left( C \int_0^t (\|
abla U_2(s)\|_{L^2} + \|
abla W_2(s)\|_{L^2}^2) \, ds \right) ,
\]

and hence since \(U(0) = W(0) = 0\), that \(U(t) = W(t) = 0\).

To show the regularity of the solutions, we will consider a Galerkin approximations of the functions \(U\) and \(W\), show uniform estimates in terms of the number of basis functions and then pass to the limit in the approximation to see the same holds for the limiting functions. Therefore, let \(\{a_j\}_{j=1}^\infty \subset L_{\text{div}}^2(\Omega)\) be a smooth basis of orthogonal eigenfunctions of the Stokes operator with eigenvalues \(\{\lambda_j\}_{j=1}^\infty\), satisfying \(\cdots \geq \lambda_j+1 \geq \lambda_j \geq \lambda_{j-1} \geq \cdots \geq \lambda_1 > 0\) and
\[
\int_\Omega a_i \cdot a_j \, dx = \delta_{ij} , \quad \nu \int_\Omega \nabla a_i : \nabla a_j \, dx = \lambda_i \delta_{ij} , \quad (A.4)
\]

where \(\delta_{ij}\) is the Kronecker delta. In addition, let \(\{d_j\}_{j=1}^\infty\) be a smooth basis of orthogonal eigenfunctions of the operator \((c_1 \Delta + c_2 \nabla \cdot \nabla)\) in \(H_0^1(\Omega)\) satisfying
\[
\int_\Omega d_i \cdot d_j \, dx = \delta_{ij} , \quad \int_\Omega (c_1 \nabla d_i : \nabla d_j + c_2 \text{div } d_i \text{ div } d_j) \, dx = \xi_i \delta_{ij} , \quad (A.5)
\]

where \(\{\xi_i\}_{i=1}^\infty\) are the eigenvalues of the operator. We denote by \(U_N\) and \(W_N\) the functions
\[
U_N = \sum_{j=1}^N \alpha_{j,N}(t) a_j , \quad W_N = \sum_{j=1}^N \beta_{j,N}(t) d_j ,
\]

where \(\alpha_{j,N}\) and \(\beta_{j,N}\) satisfy the equations, for \(j = 1, \ldots, N,\)
\[
\frac{d}{dt} \int_\Omega U_N \cdot a_j \, dx + \int_\Omega (U_N \cdot \nabla)U_N \cdot a_j \, dx + (\nu + \nu_r) \int_\Omega \nabla U_N : \nabla a_j \, dx = 2\nu_r \int_\Omega \text{curl } W_N \cdot a_j \, dx
\]
\[
\frac{d}{dt} \int_\Omega W_N \cdot d_j \, dx + \int_\Omega (U_N \cdot \nabla)W_N \cdot d_j \, dx + c_1 \int_\Omega \nabla W_N : \nabla d_j \, dx + c_2 \int_\Omega \text{div } W_N \text{ div } d_j \, dx
\]
\[
= -4\nu_r \int_\Omega W_N \cdot d_j \, dx + 2\nu_r \int_\Omega \text{curl } U_N \cdot d_j \, dx.
\quad (A.6)
\]
Using (A.4) and (A.5), this can be simplified to
\[
\frac{d}{dt} \alpha_{j,N}(t) + \sum_{k,l=1}^{N} \alpha_{k,N}(t) \alpha_{l,N}(t) \int_{\Omega} (a_k \cdot \nabla) a_l \cdot a_j \, dx + \left(1 + \frac{\nu_t}{\nu}\right) \lambda_j \alpha_{j,N}(t) = 2\nu_t \sum_{k=1}^{N} \beta_{k,N}(t) \int_{\Omega} \text{curl} \, d_k \cdot a_j \, dx \quad (A.7)
\]
\[
\frac{d}{dt} \beta_{j,N}(t) + \sum_{k,l=1}^{N} \alpha_{k,N}(t) \beta_{l,N}(t) \int_{\Omega} (a_k \cdot \nabla) d_k \cdot d_j \, dx + \xi_j \beta_{j,N}(t) + 4\nu_t \beta_{j,N}(t) = 2\nu_t \sum_{k=1}^{N} \alpha_{k,N}(t) \int_{\Omega} \text{curl} a_k \cdot d_j \, dx. \quad (A.8)
\]
Equations (A.7)–(A.8) is a nonlinear, locally Lipschitz, system of ODEs with initial data
\[
\alpha_{j,N}^{0} = \int_{\Omega} U_0 \cdot a_j \, dx, \quad \beta_{j,N}^{0} = \int_{\Omega} W_0 \cdot a_j \, dx,
\]
and therefore a solution exists on some time interval \([0,T]\). The existence on the full time interval \([0,T]\) follows as in the case of the Navier-Stokes equations by deriving a uniform in time bound on the \(\alpha_{j,N}\) and \(\beta_{j,N}\) which results in an energy inequality for \(U_N\) and \(W_N\) and yields \(U_N, W_N \in L^{\infty}(0,T; L^2(\Omega)) \cap L^2(0,T; H^{1}_0(\Omega))\) uniformly in \(N\). Passing to the limit \(N \to \infty\) and using the uniform apriori estimates, one concludes existence of limiting functions \(U\) and \(W\) solving (A.1). The regularity follows from the following lemmas:

**Lemma A.2.** Let the initial data \(U_0\) and \(W_0 \in H^2(\Omega)\) and \(\text{div} \, U_0 = 0\). Then
\[
\partial_t U, \partial_t W \in L^\infty(0,T; L^2(\Omega)) \cap L^2(0,T; H^1(\Omega)).
\]

**Proof.** In the Galerkin formulation (A.6), we multiply by \(\alpha'_{j,N}(t)\) and \(\beta'_{j,N}(t)\), add the resulting equations and sum over \(j\):
\[
\|\partial_t U_N(t)\|_{L^2}^2 + \|\partial_t W_N(t)\|_{L^2}^2 = (\nu + \nu_t) \int_{\Omega} \Delta U_N \partial_t U_N + c_1 \int_{\Omega} \Delta W_N \partial_t W_N \, dx \\
+ c_2 \int_{\Omega} \nabla \text{div} \, W_N \partial_t W_N - \int_{\Omega} (U_N \cdot \nabla) U_N \cdot \partial_t U_N \, dx - \int_{\Omega} (U_N \cdot \nabla) W_N \cdot \partial_t W_N \, dx \\
+ 2\nu_t \int_{\Omega} \text{curl} \, W_N \cdot \partial_t U_N \, dx - 4\nu_t \int_{\Omega} W_N \partial_t W_N \, dx + 2\nu_t \int_{\Omega} \text{curl} \, U_N \cdot \partial_t W_N \, dx.
\]
We estimate the right hand side at \(t = 0\):
\[
\|\partial_t U_N(0)\|_{L^2}^2 + \|\partial_t W_N(0)\|_{L^2}^2 \leq C \|\Delta U_N(0)\|_{L^2} + C \|\nabla^2 W_N(0)\|_{L^2} \|\partial_t W_N(0)\|_{L^2} \\
+ C \|U_N\|_{L^2} \|\nabla U_N(0)\|_{L^4} + C \|W_N(0)\|_{L^4} \|\nabla W_N(0)\|_{L^4} + C \|U_N(0)\|_{L^4} \|\nabla W_N(0)\|_{L^2} \\
+ C \|W_N(0)\|_{L^2} \|\partial_t W_N(0)\|_{L^2} + C \|\nabla W_N(0)\|_{L^2} \|\partial_t W_N(0)\|_{L^2}.
\]
Hence, using Ladyshenskaya’s inequality, and \(\|U_N^0\|_{H^2} \leq C \|U_0\|_{H^2}, \|W_N^0\|_{H^2} \leq C \|W_0\|_{H^2}\), we obtain
\[
\|\partial_t U_N(0)\|_{L^2}^2 + \|\partial_t W_N(0)\|_{L^2}^2 \leq C \|U_0\|_{H^2}^2 + C \|W_0\|_{H^2}^2 \leq C(\|U_0\|_{H^2} + \|W_0\|_{H^2}^2). \quad (A.9)
\]
Therefore \(\partial_t U_N(0), \partial_t W_N(0) \in L^2(\Omega)\) uniformly in \(N\).

Next, we differentiate the equations (A.6) in time and use \(\partial_t U_N\) and \(\partial_t W_N\) respectively as test functions:
\[
\frac{1}{2} \frac{d}{dt} \left( \|\partial_t U_N\|_{L^2}^2 + \|\partial_t W_N\|_{L^2}^2 \right) + \nu \|\nabla \partial_t U_N\|_{L^2}^2 + c_1 \|\nabla \partial_t W_N\|_{L^2}^2 + c_2 \|\text{div} \, \partial_t W_N\|_{L^2}^2 \\
= 2\nu_t \int_{\Omega} \text{curl} \, W_N \cdot \partial_t U_N \, dx - \nu_t \|\text{curl} \, U_N\|_{L^2}^2 - 4\nu_t \|\partial_t W_N\|_{L^2}^2 \\
- \int_{\Omega} (U_N \cdot \nabla) U_N \cdot \partial_t U_N \, dx - \int_{\Omega} (U_N \cdot \nabla) \partial_t U_N \cdot \partial_t U_N \, dx.
\]
\[-\int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot \partial_t W_N dx - \int_{\Omega} (U_N \cdot \nabla) \partial_t W_N \cdot \partial_t W_N dx\]
\[+ 2\nu_r \int_{\Omega} \text{curl} \partial_t U_N \cdot \partial_t W_N dx\]
\[= -\nu_r \|\text{curl} \partial_t U_N - 2\partial_t W_N\|^2_{L^2} - \int_{\Omega} (\partial_t U_N \cdot \nabla) U_N \cdot \partial_t U_N dx\]
\[= \int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot \partial_t W_N dx.\]

The first term on the right hand side is nonpositive, so it remains to bound the other two terms. We use again Ladyshenskaya’s and Young’s inequality:
\[
\left| \int_{\Omega} (\partial_t U_N \cdot \nabla) U_N \cdot \partial_t U_N dx \right| \leq \|\partial_t U_N\|_{L^4}^2 \|\nabla U_N\|_{L^2}
\leq \|\nabla \partial_t U_N\|_{L^2} \|\partial_t U_N\|_{L^2} \|\nabla U_N\|_{L^2}
\leq \frac{\nu'}{4} \|\nabla \partial_t U_N\|_{L^2}^2 + \frac{C}{\nu} \|\partial_t U_N\|_{L^2}^2 \|\nabla U_N\|_{L^2}^2,
\]
and similarly,
\[
\left| \int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot \partial_t W_N dx \right| \leq \|\partial_t W_N\|_{L^4} \|\partial_t U_N\|_{L^4} \|\nabla U_N\|_{L^2}
\leq \|\nabla \partial_t U_N\|_{L^2}^{1/2} \|\partial_t U_N\|_{L^2}^{1/2} \|\nabla \partial_t W_N\|_{L^2}^{1/2} \|\partial_t W_N\|_{L^2}^{1/2} \|\nabla W_N\|_{L^2}
\leq C \|\nabla \partial_t U_N\|_{L^2} \|\partial_t U_N\|_{L^2} \|\nabla W_N\|_{L^2}
+ C \|\nabla \partial_t W_N\|_{L^2} \|\partial_t W_N\|_{L^2} \|\nabla W_N\|_{L^2}
\leq \frac{\nu'}{4} \|\nabla \partial_t U_N\|_{L^2}^2 + \frac{C}{\nu} \|\partial_t U_N\|_{L^2}^2 \|\nabla W_N\|_{L^2}^2
+ \frac{c_1}{2} \|\nabla \partial_t W_N\|_{L^2}^2 + \frac{C}{c_1} \|\partial_t W_N\|_{L^2}^2 \|\nabla W_N\|_{L^2}^2.
\]

Therefore,
\[
\frac{1}{2} \frac{d}{dt} \left( \|\partial_t U_N\|_{L^2}^2 + \|\partial_t W_N\|_{L^2}^2 \right) + \frac{\nu'}{2} \|\nabla \partial_t U_N\|_{L^2}^2 + \frac{c_1}{2} \|\nabla \partial_t W_N\|_{L^2}^2
\leq C \nu \|\partial_t U_N\|_{L^2} \|\nabla U_N\|_{L^2} + \frac{C}{c_1} \|\partial_t W_N\|_{L^2} \|\nabla W_N\|_{L^2},
\]

Since \(\|\nabla U_N\|_{L^2}^2 + \|\nabla W_N\|_{L^2}^2 \in L^1([0,T])\), we can use Grönwall’s inequality together with (A.9) to conclude that
\[
\sup_{t \in [0,T]} \left( \|\partial_t U_N\|_{L^2}^2 + \|\partial_t W_N\|_{L^2}^2 \right) + \int_0^T \left( \|\nabla \partial_t U_N\|_{L^2}^2 + \|\nabla \partial_t W_N\|_{L^2}^2 \right) dt \leq C.
\]

This bound holds uniformly in \(N\), and hence after passing \(N \to \infty\) also for \(U\) and \(W\). \(\square\)

Using this, we can prove the following lemma:

**Lemma A.3.** Let the initial data \(U_0\) and \(W_0\) \(\in H^2(\Omega)\) and \(\text{div} U_0 = 0\) and assume that the domain \(\Omega\) is at least of class \(C^2\). Then
\[
U, W \in L^\infty(0,T; H^2(\Omega)).
\]

**Proof.** We write equations (A.1) in the variational form
\[
(\nu + \nu_r) \int_{\Omega} \nabla U(t) : \nabla \psi_1 dx = \int_{\Omega} g_1(t) \psi_1 dx,
\]
\[
\int_{\Omega} (c_1 \nabla W(t) : \nabla \psi_2 + c_2 \text{div} W(t) \text{div} \psi_2) dx + 4\nu_r \int_{\Omega} W(t) \cdot \psi_2 dx = \int_{\Omega} g_2(t) \psi_2 dx,
\]
(A.10)
for any \( \psi_1 \in H^1_0(\Omega), \psi_2 \in H^1_0(\Omega) \), where \( g_1, g_2 \) are given by

\[
\begin{align*}
g_1(t) &= 2\nu_r \text{curl } \mathbf{w}(t) - \partial_t \mathbf{u}(t) - (\mathbf{u}(t) \cdot \nabla) \mathbf{u}(t), \\
g_2(t) &= 2\nu_r \text{curl } \mathbf{w}(t) - \partial_t \mathbf{w}(t) - (\mathbf{u}(t) \cdot \nabla) \mathbf{w}(t).
\end{align*}
\]

The left hand sides in (A.10) are elliptic bilinear forms, and the right hand sides satisfy, using Lemma A.2 and the calculations in equations (3.102) in [30, Chapter III],

\[
\partial_t \mathbf{u}, \partial_t \mathbf{w} \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)),
\]

\[
\text{curl } \mathbf{u}, \text{curl } \mathbf{w} \in L^\infty(0, T; L^2(\Omega)) \cap H^1(0, T; L^2(\Omega)),
\]

\[
(\mathbf{u} \cdot \nabla) \mathbf{u}, (\mathbf{u} \cdot \nabla) \mathbf{w} \in L^\infty(0, T; L^{4/3}(\Omega)),
\]

and hence \( g_1, g_2 \in L^\infty(0, T; L^{4/3}(\Omega)) \). Using Proposition 1.2.2 in [30] for \( \mathbf{u} \) and elliptic regularity theory for \( \mathbf{w} \), we obtain that \( \mathbf{u}, \mathbf{w} \in L^\infty(0, T; W^{2,3/2}(\Omega)) \). Hence by the Sobolev embedding, we obtain that \( \mathbf{u}, \mathbf{w} \in L^\infty((0, T) \times \Omega) \). As in the proof of Theorem III.3.6 in [30], we can use this to obtain a better estimate on the convection terms and get \( g_1, g_2 \in L^\infty(0, T; L^2(\Omega)) \) and hence \( \mathbf{u}, \mathbf{w} \in L^\infty(0, T; H^2(\Omega)) \).

Higher order regularity follows from iterating this procedure and assuming that \( \mathbf{u}_0, \mathbf{w}_0 \) are regular enough:

**Lemma A.4.** Assume \( \mathbf{u}_0, \mathbf{w}_0 \in H^3(\Omega) \) with \( \text{div } \mathbf{u}_0 = 0 \) and that the domain \( \Omega \) is sufficiently smooth. Then

\[
\partial^2_t \mathbf{u}, \partial^2_t \mathbf{w} \in L^\infty(0, T; H^1(\Omega)).
\]

**Proof.** From Lemma A.2 and A.3, we have that

\[
\mathbf{u}, \mathbf{w} \in L^\infty(0, T; H^2(\Omega)), \quad \partial_t \mathbf{u}, \partial_t \mathbf{w} \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)).
\]

We consider again the Galerkin approximation (A.6). We denote \( P_N \) the projection onto the eigenfunctions \( \{a_1, \ldots, a_N\} \) and by \( Q_N \) the projection onto the eigenfunctions \( \{d_1, \ldots, d_N\} \). The projections satisfy

\[
\begin{align*}
\|P_N v\|_{L^2(\Omega)}^2 &\leq \|v\|_{L^2(\Omega)}^2, \\
\|\nabla P_N v\|_{L^2(\Omega)}^2 &\leq \|\nabla v\|_{L^2(\Omega)}^2, \\
\|Q_N v\|_{L^2(\Omega)}^2 &\leq \|v\|_{L^2(\Omega)}^2, \\
\|\nabla Q_N v\|_{L^2(\Omega)}^2 &\leq \|\nabla v\|_{L^2(\Omega)}^2 + \|\text{div } Q_N v\|_{L^2(\Omega)}^2, \\
\|\text{div } v\|_{L^2(\Omega)}^2 &\leq \|\nabla v\|_{L^2(\Omega)}^2 + \|\text{div } v\|_{L^2(\Omega)}^2.
\end{align*}
\]

Then the Galerkin formulation (A.6) can be written as

\[
\begin{align*}
\partial_t U_N &= -P_N (\mathbf{u}_0 \cdot \nabla) U_N + (\nu + \nu_r) P_N \Delta U_N + 2\nu_r P_N \text{curl } \mathbf{w}_N, \\
\partial_t W_N &= -Q_N (\mathbf{u}_0 \cdot \nabla) W_N + c_1 Q_N \Delta W_N + c_2 Q_N \nabla \text{div } \mathbf{w}_N - 4\nu_r W_N + 2\nu_r Q_N \text{curl } \mathbf{u}_N.
\end{align*}
\]

and hence taking the gradient in both equations and estimating the \( L^2 \)-norms at \( t = 0 \), using (A.11), we obtain

\[
\begin{align*}
\|\nabla \partial_t U_N(0)\|_{L^2(\Omega)} &\leq \|\nabla P_N (\mathbf{u}_0 \cdot \nabla) U_N^0\|_{L^2} + (\nu + \nu_r) \|\nabla P_N \Delta U_N^0\|_{L^2} + 2\nu_r \|\nabla P_N \text{curl } W_N^0\|_{L^2} \\
&\leq \|\nabla (\mathbf{u}_0 \cdot \nabla) U_N^0\|_{L^2} + (\nu + \nu_r) \|\nabla \Delta U_N^0\|_{L^2} + 2\nu_r \|\nabla \text{curl } W_N^0\|_{L^2} \\
&\leq \|\nabla U_N^0\|_{L^4} + \|U_N^0\|_{L^\infty} \|\nabla^2 U_N^0\|_{L^2} + (\nu + \nu_r) \|\nabla^3 U_N^0\|_{L^2} + 2\nu_r \|\nabla^2 W_N^0\|_{L^2} \\
&\leq C \|U_N^0\|_{H^3} + \|W_N^0\|_{H^2}.
\end{align*}
\]

and similarly,

\[
\begin{align*}
\|\nabla \partial_t W_N(0)\|_{L^2(\Omega)} &\leq \|\nabla Q_N (\mathbf{u}_0 \cdot \nabla) W_N^0\|_{L^2} + c_1 \|\nabla Q_N \Delta W_N^0\|_{L^2} + c_2 \|\nabla Q_N \nabla \text{div } W_N^0\|_{L^2} + 2\nu_r \|\nabla Q_N \text{curl } U_N^0\|_{L^2} + 4\nu_r \|\nabla W_N^0\|_{L^2} \\
&\leq C \|\nabla (\mathbf{u}_0 \cdot \nabla) W_N^0\|_{L^2} + C \|\nabla \Delta W_N^0\|_{L^2} + C \|\nabla \nabla \text{div } W_N^0\|_{L^2} \\
&\leq C \|U_N^0\|_{L^4} + \|W_N^0\|_{L^\infty} \|\nabla^2 W_N^0\|_{L^2} + C \|\nabla^3 W_N^0\|_{L^2} + 2\nu_r \|\nabla^2 W_N^0\|_{L^2} + 4\nu_r \|\nabla W_N^0\|_{L^2}.
\end{align*}
\]
and hence

$$\| \nabla \partial_t U_N(0) \|_{L^2} + \| \nabla \partial_t W_N(0) \|_{L^2} \leq C (\| U_0 \|_{H^3} + \| W_0 \|_{H^3}).$$

Next we multiply the Galerkin formulations (A.6) by the eigenvalues $\lambda_j$ and $\xi_j$ respectively and differentiate in time:

$$\frac{d}{dt} \int_{\Omega} \partial_t U_N \cdot \Delta a_j \, dx + \int_{\Omega} (\partial_t U_N \cdot \nabla) U_N \cdot \Delta a_j \, dx + \int_{\Omega} (U_N \cdot \nabla) \partial_t U_N \cdot \Delta a_j \, dx$$

$$= (\nu + \nu_r) \int_{\Omega} \Delta \partial_t U_N \cdot \Delta a_j \, dx + 2\nu_r \int_{\Omega} \text{curl} \partial_t W_N \cdot \Delta a_j \, dx,$n

$$\frac{d}{dt} \int_{\Omega} \partial_t W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) d_j \, dx + \int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) d_j \, dx$$

$$+ \int_{\Omega} (U_N \cdot \nabla) \partial_t W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) d_j \, dx$$

$$= c_1 \int_{\Omega} \Delta \partial_t W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) d_j \, dx + c_2 \int_{\Omega} \nabla \partial_t W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) d_j \, dx$$

$$+ 4\nu_r \int_{\Omega} \text{curl} \partial_t U_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) d_j \, dx.$n

Then we multiply by $a'_{j,N}$ and $b'_{j,N}$ respectively and sum over $j = 1, \ldots, N$,

$$\frac{d}{dt} \int_{\Omega} \| \partial_t \nabla U_N \|_{L^2}^2 \, dx - \int_{\Omega} (\partial_t U_N \cdot \nabla) U_N \cdot \Delta \partial_t U_N \, dx - \int_{\Omega} (U_N \cdot \nabla) \partial_t U_N \cdot \Delta \partial_t U_N \, dx$$

$$= - (\nu + \nu_r) \int_{\Omega} \| \Delta \partial_t U_N \|_{L^2}^2 \, dx - 2\nu_r \int_{\Omega} \text{curl} \partial_t W_N \cdot \Delta \partial_t U_N \, dx,$n

$$\frac{d}{dt} \int_{\Omega} \| (c_1 |\partial_t \nabla W_N|^2 + c_2 |\partial_t \nabla W_N|^2) \|_{L^2}^2 \, dx - \int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx$$

$$+ \int_{\Omega} (U_N \cdot \nabla) \partial_t W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx + \int_{\Omega} (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \|_{L^2}^2 \, dx$$

$$= - 4\nu_r \int_{\Omega} (c_1 |\partial_t \nabla W_N|^2 + c_2 |\partial_t \text{div} \partial_t W_N|^2) \, dx - 2\nu_r \int_{\Omega} \text{curl} \partial_t U_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx.$n

Adding the two equations and rearranging, we get

$$\frac{1}{2} \frac{d}{dt} \left( \| \nabla \partial_t U_N \|_{L^2}^2 + c_1 \| \nabla \partial_t W_N \|_{L^2}^2 + c_2 \| \text{div} \partial_t W_N \|_{L^2}^2 \right) + (\nu + \nu_r) \| \Delta \partial_t U_N \|_{L^2}^2$$

$$+ \| (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \|_{L^2}^2 + 4c_1 \nu_r \| \nabla \partial_t W_N \|_{L^2}^2 + 4c_2 \nu_r \| \text{div} \partial_t W_N \|_{L^2}^2 \right)$$

$$= \int_{\Omega} (\partial_t U_N \cdot \nabla) U_N \cdot \nabla \partial_t U_N \, dx$$

$$+ \int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx$$

$$- 2\nu_r \int_{\Omega} \text{curl} \partial_t U_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx - 2\nu_r \int_{\Omega} \text{curl} \partial_t W_N \cdot \Delta \partial_t U_N \, dx.$n

The terms on the right hand side can be estimated as follows (using Ladyshenskaya’s inequality):

$$\left| \int_{\Omega} (\partial_t U_N \cdot \nabla) W_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx \right| \leq \| \partial_t U_N \|_{L^4} \| \nabla W_N \|_{L^4} \| (c_1 \Delta + c_2 \nabla \text{div}) W_N \|_{L^2}$$

$$\leq \frac{1}{4} \| (c_1 \Delta + c_2 \nabla \text{div}) W_N \|_{L^2}^2 + C \| \partial_t U_N \|_{L^4}^2 \| \nabla W_N \|_{L^4}^2$$

$$\leq \frac{1}{4} \| (c_1 \Delta + c_2 \nabla \text{div}) W_N \|_{L^2}^2 + C \| \partial_t U_N \|_{L^4}^2 \| \partial_t \nabla U_N \|_{L^2} \| \nabla W_N \|_{L^2} \| \nabla^2 W_N \|_{L^2}$$

$$\leq \frac{1}{4} \| (c_1 \Delta + c_2 \nabla \text{div}) W_N \|_{L^2}^2 + C \| \partial_t U_N \|_{L^4}^2 + C \| \partial_t \nabla U_N \|_{L^2} \| \nabla W_N \|_{L^2} \| \nabla^2 W_N \|_{L^2}.$$
Similarly,
\[
\left| \int_{\Omega} [(U_N \cdot \nabla) \partial_t W_N] \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx \right| \leq \| U_N \|_{L^\infty} \| \partial_t \nabla W_N \|_{L^2} \| (c_1 \Delta + c_2 \nabla \text{div}) W_N \|_{L^2} \\
\leq \frac{1}{4} \| (c_1 \Delta + c_2 \nabla \text{div}) W_N \|_{L^2}^2 + C \| U_N \|_{L^\infty} \| \nabla \partial_t W_N \|_{L^2}.
\]
and replacing \( W_N \) by \( U_N \), also
\[
\left| \int_{\Omega} [(\partial_t U_N \cdot \nabla) U_N] \cdot \Delta \partial_t U_N \, dx \right| \leq \| \partial_t U_N \|_{L^4} \| \nabla U_N \|_{L^4} \| \Delta \partial_t U_N \|_{L^4} \\
\leq \frac{\nu}{4} \| \Delta \partial_t U_N \|_{L^4}^2 + C \frac{\nu}{\nu} \| \partial_t U_N \|_{L^4} \| \nabla U_N \|_{L^4}^2 \\
\leq \frac{\nu}{4} \| \Delta \partial_t U_N \|_{L^4}^2 + C \frac{\nu}{\nu} \| \partial_t U_N \|_{L^4} \| \nabla U_N \|_{L^4}^2 \| \nabla^2 U_N \|_{L^2}.
\]
The remaining two terms can be estimated as
\[
2\nu \left| \int_{\Omega} \text{curl} \partial_t U_N \cdot (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \, dx \right| \leq \frac{1}{4} \| (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \|_{L^2}^2 + C \nu^2 \| \nabla \partial_t U_N \|_{L^2}^2
\]
and
\[
2\nu \left| \int_{\Omega} \text{curl} \partial_t W_N \cdot \Delta \partial_t U_N \, dx \right| \leq \frac{\nu}{4} \| \Delta \partial_t U_N \|_{L^2}^2 + C \frac{\nu}{\nu} \| \nabla \partial_t W_N \|_{L^2}^2.
\]
Hence, we can upper bound in equation \( (A.12) \)
\[
\frac{1}{2} \frac{d}{dt} \left( \| \nabla \partial_t U_N \|_{L^2}^2 + \| \nabla \partial_t W_N \|_{L^2}^2 \right) + \frac{\nu}{4} \| \Delta \partial_t U_N \|_{L^2}^2 + \frac{1}{4} \| (c_1 \Delta + c_2 \nabla \text{div}) \partial_t W_N \|_{L^2}^2 \\
\leq C \| \partial_t \nabla U_N \|_{L^2} \| \nabla W_N \|_{L^2} \| \nabla^2 W_N \|_{L^2} \\
+ C \| \partial_t U_N \|_{L^2}^2 + C \| \partial_t \nabla U_N \|_{L^2} \| \nabla W_N \|_{L^2} \| \nabla^2 W_N \|_{L^2} \\
+ C \| U_N \|_{L^\infty} \| \nabla \partial_t W_N \|_{L^2} \| \partial_t U_N \|_{L^2}^2 + C \frac{\nu}{\nu} \| \partial_t \nabla U_N \|_{L^2} \| \nabla W_N \|_{L^2} \| \nabla^2 U_N \|_{L^2} \\
+ C \frac{\nu}{\nu} \| \nabla \partial_t U_N \|_{L^2} \| \nabla U_N \|_{L^\infty} \| \partial_t U_N \|_{L^2}^2 + C \frac{\nu}{\nu} \| \nabla \partial_t W_N \|_{L^2}.
\]
Thanks to Lemmas A.2 and A.3, the right hand side can be bounded uniformly in \( t \in [0, T] \) by
\[
C_{\nu, \nu', c_1} \left( \| \nabla \partial_t U_N \|_{L^2}^2 + \| \nabla \partial_t W_N \|_{L^2}^2 \right) + C_{\nu, \nu', c_1},
\]
and an application of the Grönwall inequality and letting \( N \to \infty \) yields the result.

\[\square\]

**Lemma A.5.** Assume \( U_0, W_0 \in H^3(\Omega) \) with \( \text{div} U_0 = 0 \). Then
\[
U, W \in L^\infty(0, T; H^3(\Omega)).
\]

**Proof.** We proceed as in Lemma A.3 and write the equations in the form \( (A.10) \). From Lemma A.3, we already get that
\[
\text{curl} W, \text{curl} U, (U \cdot \nabla) U, (U \cdot \nabla) W \in L^\infty(0, T; H^1(\Omega)).
\]
Lemma A.4 additionally yields that
\[
\partial_t U, \partial_t W \in L^\infty(0, T; H^1(\Omega)).
\]
Hence \( g_1(t), g_2(t) \in H^1(\Omega) \) for almost every \( t \). Thus Proposition 1.2.2 in [30] and elliptic regularity imply that

\[
U, W \in L^\infty(0,T; H^3(\Omega)).
\]

\[ \square \]

**Remark A.6.** One could iterate this further to achieve even more regularity of \( U \) and \( W \) under the assumption that the domain and the initial data are smooth enough.

**Remark A.7.** Notice that this implies that \( \text{Remark A.7.} \)

\[
\text{Remark A.7. Notice that this implies that } U, W \in L^\infty(0,T; \text{Lip}(\Omega)). \quad \text{In addition, } U, W, H = \nabla \Phi \text{ satisfy an energy balance with equality:}
\]

\[
\frac{1}{2} \frac{d}{dt} \int_\Omega (|U|^2 + |W|^2 + \mu_0(1 + \kappa_0)|H|^2) \, dx
\]
\[
+ \int_\Omega (\nu|\nabla U|^2 + c_1|\nabla W|^2 + c_2|\text{div } U|^2 + \nu_\epsilon|\text{curl } U - 2W|^2) \, dx = \mu_0 \int_\Omega \partial_t h_n H \, dx.
\]

In a very similar way, one can prove uniqueness and regularity of solutions locally in time for the three-dimensional case (see also [30, Theorem III.3.11] and [1]). We state the result here without proof:

**Theorem A.8.** Let \( d = 3 \) and assume \( U_0, W_0 \in H^3(\Omega) \) with \( \text{div } U_0 = 0 \) and that the domain \( \Omega \) and the boundary data \( h_n \) are sufficiently smooth. Then there exists \( T^* > 0 \) such that the solution of (1.10) satisfies

\[
\partial_t U, \partial_t W, \partial_t H \in L^\infty(0,T^*; H^1(\Omega)) \cap L^2(0,T^*; H^2(\Omega)) \quad \text{and} \quad U, W, H \in L^\infty(0,T^*; H^3(\Omega)).
\]

**Appendix B. Adoptions needed to prove existence of weak solutions in [2] for chosen boundary conditions**

The goal of this section is to explain the adoptions that have to be made in the proof of existence of weak solutions for (3.1) to accommodate the boundary conditions

\[
h^\sigma \cdot n = (h_n - m^\sigma) \cdot n, \quad \text{on } [0,T] \times \partial \Omega, \tag{B.1}
\]

for the magnetizing field \( h^\sigma \) and the natural boundary conditions

\[
\text{div } m^\sigma = 0, \quad \text{curl } m^\sigma \times n = 0, \quad \text{on } [0,T] \times \partial \Omega, \tag{B.2}
\]

for the magnetization \( m^\sigma \) instead of

\[
h^\sigma \cdot n = 0, \quad \text{on } [0,T] \times \partial \Omega,
\]

and

\[
m^\sigma \cdot n = 0, \quad \text{curl } m^\sigma \times n = 0, \quad \text{on } [0,T] \times \partial \Omega, \tag{B.3}
\]

respectively, as in [2]. With boundary conditions (B.2), the solution \( m^\sigma(t) \) is sought in the space \( K \) as defined in (3.3) instead of

\[
K_0 = \{ v \in L^2(\Omega) \mid \text{div } v, \text{curl } v \in L^2(\Omega), v \cdot n = 0 \text{ on } \partial \Omega \} = \{ v \in H^1(\Omega) \mid v \cdot n = 0 \text{ on } \partial \Omega \},
\]

as in [2]. The reason why we need to do this, is that in the Galerkin approximation for the existence proof in [2, pp. 336–343], one would like to take the approximation of \( h^\sigma \) as a test function in the weak formulation for the approximation of \( m^\sigma \) to obtain an energy inequality. With boundary conditions (B.1), the approximation of \( h^\sigma \) is not in the space \( K_0 \) and hence not a valid test function. By changing the function space for \( m^\sigma \) to \( K \), \( h^\sigma \) and its approximations become a valid test function.

\( K \) equipped with inner product

\[
\langle q_1, q_2 \rangle := \int_\Omega q_1 \cdot q_2 \, dx + \int_\Omega \text{div } q_1 \text{ div } q_2 \, dx + \int_\Omega \text{curl } q_1 \cdot \text{curl } q_2 \, dx.
\]

is a Hilbert space and has a subspace

\[
N := \text{span} \{ v \in H^1(\Omega) \mid v = \nabla \psi, \text{ for some } \psi \in H^2(\Omega) \} \subseteq K.
\]
Let $N^\perp$ be the orthogonal complement of this subspace. We can find a smooth orthonormal basis $\{\nabla \eta_j \}_{j=1}^\infty$ of $N$ and a smooth orthonormal basis $\{\theta_j \}_{j=1}^\infty$ of its complement $K^\perp$ such that $\{\nabla \eta_j \}_{j=1}^\infty \cup \{\theta_j \}_{j=1}^\infty$ is an orthonormal basis of $K$. The boundary conditions (B.2) are natural and incorporated in the weak formulation for the magnetization $m^\sigma$ instead of the function space as in the case of the boundary condition $m^\sigma \cdot n = 0$. Indeed, for a smooth vector field $v$ satisfying (B.2) and a test function $q \in K$, it holds

$$-\int_\Omega \Delta v \cdot q \, dx = \int_\Omega \text{curl} v \cdot \text{curl} q \, dx + \int_\Omega \text{div} v \text{ div} q \, dx - \int_{\partial \Omega} (\text{curl} v \times n) \cdot q \, ds - \int_{\partial \Omega} v q \cdot n \, ds$$

and hence the correct weak formulation of (3.1d) is (3.7), the same as for boundary conditions (B.3) except that in the case of (B.3), the test functions should be taken in the space $K_0$.

In the Galerkin approximation for the existence proof ([2, p. 337]), one then instead defines $m^{\sigma}_n$ and $h^{\sigma}_n$, the approximations at level $n$, by

$$m^{\sigma}_n = \sum_{j=1}^n \gamma'^n_j(t) \theta_j + \sum_{j=n+1}^n \gamma'^n_{j+n}(t) \nabla \eta_j, \quad h^{\sigma}_n = \nabla \varphi'^n_n, \quad \text{with} \quad \varphi'^n_n = \sum_{j=1}^n \delta'^n_j(t) \eta_j,$$

where $\eta_j$ and $\theta_j$ are as in the orthonormal bases of $N$ and $N^\perp$ and $\gamma'^n_j$ and $\delta'^n_j$ are defined from the conditions $(j = 1, \ldots, n)$

$$\frac{d}{dt} \int_\Omega m^{\sigma}_n \cdot \nabla \eta_j \, dx + \int_\Omega \left[ (u^{\sigma}_n \cdot \nabla) \eta_j \right] \cdot \nabla \eta_j \, dx + \sigma \int_\Omega \text{div} m^{\sigma}_n \Delta \eta_j \, dx$$

$$= \int_\Omega (w^{\sigma}_n \times \nabla \eta_j) \cdot \nabla \eta_j \, dx - \frac{1}{\tau} \int_\Omega (m^{\sigma}_n - \kappa_0 h^{\sigma}_n) \cdot \nabla \eta_j \, dx,$$

$$\frac{d}{dt} \int_\Omega m^{\sigma}_n \cdot \theta_j \, dx + \int_\Omega \left[ (u^{\sigma}_n \cdot \nabla) \eta_j \right] \cdot \theta_j \, dx + \sigma \int_\Omega \text{curl} m^{\sigma}_n : \text{curl} \theta_j \, dx = \int_\Omega (w^{\sigma}_n \times \nabla \eta_j) \cdot \theta_j \, dx - \frac{1}{\tau} \int_\Omega (m^{\sigma}_n - \kappa_0 h^{\sigma}_n) \cdot \theta_j \, dx,$$

$$m^{\sigma}_n(0, \cdot) = m_0, \quad \Omega \int_\Omega \nabla \varphi'^n_n \cdot \nabla \eta_j \, dx = - \int_\Omega (m^{\sigma}_n - h_n) \nabla \eta_j \, dx;$$

where $m_0, n$ is the orthogonal projection of $m_0$ in $L^2(\Omega)$ onto the space spanned by $\{\nabla \eta_j \}_{j=1}^n \cup \{\theta_j \}_{j=1}^n$.

Then one proceeds as in the existence proof in [2]. The only other difference is that since $\{m^{\sigma}_n \}_n \subset K$ instead of $H^1(\Omega)$, one needs to use the Div-Curl Lemma (see e.g. [9, Theorem 5.2.1]) to obtain that the space $K$ is compact in $L^2(\Omega)$ (instead of Rellich’s theorem as for the embedding $H^1(\Omega) \subset L^2(\Omega)$) and then apply the Aubin-Lions Lemma with this space to obtain strong convergence in $L^2$ of a subsequence of $\{m^{\sigma}_n \}_n$ to some limiting function $m^{\sigma}$.
