Abstract

The critical behavior of a quenched random hypercubic sample of linear size $L$ is considered, within the “random-$T_c$” field-theoretical model, by using the renormalization group method. A finite-size scaling behavior is established and analyzed near the upper critical dimension $d = 4 - \epsilon$ and some universal results are obtained. The problem of self-averaging is clarified for different critical regimes.

I. INTRODUCTION

The description of effects of disorder on the critical behavior of finite-size systems have attracted a lot of interest [1–8]. Up to now a discussion takes place of whether the introduced disorder influences the finite-size scaling (FSS) results [3,8], compared to the standard FSS results, known for pure systems [9–11]. A formulation of general FSS concepts for the case of disorder is strongly complicated due to the additional averaging over the different random samples. For a random sample with volume $L^d$, where $L$ is a linear dimension, any observable property $X$, singular in the thermodynamic limit, has different values for different realizations of the randomness and can be considered as stochastic variable with mean $\overline{X}$ and variance $(\Delta X)^2 := \overline{X^2} - \overline{X}^2$, where the over line indicates an average over all realizations of the randomness. Here, an important theoretical problem of interest is related with the property of self-averaging (SA) [12]. If the system does not exhibit SA a measurement performed on a single sample does not give a meaningful result and must be repeated on many samples. A numerical study of such a system also will be quite difficult.

This point has been studied recently by means of FSS arguments [1,4], renormalization group (RG) analysis [2,5] and Monte Carlo simulations [4,6]. The quantity under inspection is the relative variance $R_X(L) := (\Delta X)^2 / \overline{X^2}$. A system is said to exhibit “strong SA” if $R_X(L) \sim L^{-d}$ as $L \to \infty$. This is the case if the system is away from criticality, i.e. if $L \gg \xi$. At the criticality, i.e. when $L \ll \xi$, the situation depends whether the randomness is irrelevant ($\nu_{\text{pure}} > 2/d$, e.g. “pure”, P-case) or relevant ($\nu_{\text{random}} > 2/d$, e.g. “random” R-case) [2]. One calls the former case “weak SA”, since $R_X(L) \sim L^{(\alpha/\nu_{\text{pure}})}$, and the latter case “no SA”, since $R_X(L)$ is fixed nonzero universal quantity even in the thermodynamic limit [2].

The lack of SA in disordered systems implies that the standard FSS breaks down. Thus, one needs to formulate a FSS theory, suitable for the case under consideration. There is an ongoing activity in this field but an understanding of the problems at a deeper level is still desirable [1,2,8].

The successful application of the field theoretical methods [13,14] for the analytic calculations of the size-dependent universal scaling functions for pure systems makes the possible extension of these methods very appealing also in the case of disordered systems. The appropriate field theory is the $N$-component $\psi^4$ theory with a “random- $T_c$” term [15–21]. The analytic difficulties raised by the disorder usually are avoided with the replica trick by solving an effective pure problem [17]. However, the perturbative structure of the theory is still much more complicated than for the corresponding pure system, arising additional difficulties in the applicability of the ideas proposed in [13,14]. Some of them are of rather hard computational nature.

Between the generic models for magnetism, the most popular and relatively well studied by means of Monte Carlo simulations is the Ising model (i.e. $N = 1$) due to the fact that in three dimensions it is the model for which in accordance with the Harris criterion, randomness is relevant. But its RG analysis is complicated as a result of the well known accidental degeneracy in the recursion relations that needs higher order in $\epsilon$ and so the use of the loop expansion to second order (see e.g. [15,18–20]). This leads to the apparent computational difficulties in the finite-size treatment of the system. The $\epsilon$- calculations based
on the loop expansion to second order are not done even for the pure finite-size systems. In this situation, more attractive for the finite-size RG study are the disordered XY ($N = 2$) and Heisenberg ($N = 3$) cases as simpler and having the same qualitative features governed in $d = 4 - \epsilon$ dimensions by a random fixed point.

Other problems have more basic nature and are related with the breaking of the replica symmetry (see [22]). Since its deeper understanding is still lacking, they are beyond of our interest in the present study.

In this paper we analyze the finite-size properties of an $N$-component ($N > 1$) model of randomly diluted magnet with hypercubic geometry of linear size $L$. Exact calculations are performed in the mean-field regime $d > 4$, and up to the first order in $\epsilon$ near the upper critical dimension $d_c = 4$. Although in this case, the problem of usefulness of the corresponding series expansions away from the dimension $d = 4 - \epsilon$ arises and is questionable (see [23] and refs. therein), we shall show that many generic FSS properties of the model can be established and we hope this would have implications for more realistic cases.

The paper is organized as follow. In Sections II and III we define the model and the effective Hamiltonian. In Section IV we perform the analysis in the zero-mode approximation. In Sections V and VI we give the expressions for the shift of the critical temperature and the renormalized coupling constants in first order in $\epsilon$. Section VII deals with the verification of the FSS and the analysis of the problem of Self-Averaging is given in Section VIII. Finally in Section IX we present our main conclusions.

II. MODEL

We consider the "random - $T_c$" Ginzburg-Landau-Wilson model of disordered ferromagnets (see, e.g. [15–20])

$$
\mathcal{H}_r = -\frac{1}{2} \int_{L^d} d^d x [t |\psi(x)|^2 + \varphi(x)|\psi(x)|^2 + c|\nabla \psi(x)|^2 + \frac{u}{12} |\psi(x)|^4],
$$

where $\psi(x)$ is a $N$-component field with $\psi^2(x) = \sum_{i=1}^N \psi_i^2(x)$ and the random variable $\varphi(x)$ has a Gaussian distribution

$$
P(\varphi(x)) = \frac{\exp[-\frac{\varphi(x)^2}{2\epsilon}]}{\sqrt{2\pi\Delta}}
$$

with mean

$$
\overline{\varphi(x)} = 0
$$

and variance

$$
\overline{\varphi(x)\varphi(x')} = \Delta \delta^d(x - x').
$$

The over line in (2.4) indicates a random average performed with the distribution $P(\varphi(x))$. Here we will consider a system in a finite cube of volume $L^d$ with periodic boundary conditions. This means that the following expansion takes place
\[ \psi(x) = \frac{1}{L^d} \sum_k \tilde{\psi}(k) \exp(ik \cdot x) \]  

(2.5)

and

\[ \varphi(x) = \frac{1}{L^d} \sum_k \tilde{\varphi}(k) \exp(ik \cdot x), \]  

(2.6)

where \( k \) is a discrete vector with components \( k_i = 2\pi n_i / L \), \( n_i = 0, \pm 1, \pm 2, \ldots \), \( i = 1, \ldots, d \) and a cutoff \( \Lambda \sim a^{-1} \) (\( a \) is the lattice spacing). In this paper, we are interested in the continuum limit, i.e. \( a \to 0 \).

In our case of quenched randomness one must average the logarithm of the partition function over the Gaussian distribution (2.2) to produce the free energy

\[ F[H_r] = -\int_{-\infty}^{\infty} D\varphi(x)P(\varphi(x)) \ln Z_r, \]  

(2.7)

where

\[ Z_r = Tr_\psi \exp[H_r]. \]  

(2.8)

It is well known that the direct average of \( H_r \) over the Gaussian leads to equivalent results [24] for the critical behavior as the \( n = 0 \) limit of the following "pure" translationally invariant model [25]

\[ H_p(n) = -\frac{1}{2} \sum_{\alpha=1}^{n} \int_{L^d} d^d x [t|\psi_\alpha(x)|^2 + c|\nabla \psi_\alpha(x)|^2 + \frac{u}{12}|\psi_\alpha(x)|^4] \]

\[ + \frac{\Delta}{8} \sum_{\alpha,\beta=1}^{n} \int_{L^d} d^d x |\psi_\alpha(x)|^2 |\psi_\beta(x)|^2. \]  

(2.9)

Here \( \psi_\alpha(x), \alpha = 1, \ldots, n \) (\( n \) being the number of replicas) are components of an \((n \times N)\)-components field \( \tilde{\psi}(x) \). Because of this equivalence, the model \( H_p \) has been the object of intensive field-theoretical studies (see [23] and refs. therein) in the bulk case. Much less is known for the equivalence of \( H_r \) and the \( n = 0 \)-limit of \( H_p \) in the finite-size case. Problems may arise when finite-size techniques are used, since both procedures \( L \to \infty \) and removing of disorder by the "trick" \( n \to 0 \) may not commute.

III. THE EFFECTIVE HAMILTONIAN

In this work we will use the RG technique introduced in [13] and [14] for studying pure systems with finite geometry. This technique permits explicit analytical calculations above and in the neighborhood of the upper critical dimension. The main idea is to expand the field in (2.1) in Fourier modes and then to treat the zero mode separately from the nonzero modes. The nonzero modes can be treated by the methods developed for the bulk systems (e.g. loop expansion), while the zero mode, whose fluctuations are damped at the critical temperature, has to be treated exactly. This overcomes the problems due to the infrared (IR) divergences that take place in finite size systems (see reference [23]).
In our more complicated case we have two possibilities: to consider the random model Eq. (2.1) or to consider the replicated pure model Eq. (2.9). The last one is closer to the case treated in [13] and [14] by getting around the difficulties due to random average performed with \( P(\varphi(x)) \) and is used in the present study. For this case, the replicated partition function is given by

\[
Z_p(n) = \int \mathcal{D}\psi \exp[\mathcal{H}_p(n)].
\]  

(3.1)

We decompose the field \( \psi(x) \) into a zero momentum component \( \phi = L^{-d} \int d^d x \psi(x) \), which plays the role of the uniform magnetization and a second part depending upon the non-zero modes \( \sigma = L^{-d} \sum_{\mathbf{k} \neq 0} \psi(k) \exp(-i k \cdot x) \). After some algebra, the partition function can be expressed as

\[
Z_p(n) = \int \mathcal{D}\phi \mathcal{D}\sigma \exp \left\{ -\frac{L^d}{2} \sum_{\alpha=1}^{n} \left( r_0 \phi_\alpha^2 + \frac{u_0}{12} \phi_\alpha^4 \right) + \frac{L^d \Delta_0}{8} \left( \sum_{\alpha=1}^{n} \phi_\alpha^2 \right)^2 \right. \\
- \frac{1}{2} \sum_{\alpha=1}^{n} \sum_{\mathbf{k}} \left[ r_0 + k^2 + \frac{u_0}{2} \phi_\alpha^2 - \frac{\Delta_0}{2} \sum_{\beta=1}^{n} \phi_\beta^2 \right] \sigma_\alpha^2 + \text{higher powers of } \sigma \right\}. 
\]  

(3.2)

Here the terms involving \( \int d^d x \sigma \) vanishes since \( \sigma \) depends only on non zero modes. The terms containing \( \sigma \) are treated using diagram expansion, leading to the effective Hamiltonian in the one-loop approximation

\[
\mathcal{H}_p^{\text{eff}}(n) = -\frac{L^d}{2} \sum_{\alpha=1}^{n} \left( \tilde{t}(n) \phi_\alpha^2 + \frac{\tilde{u}(n)}{12} \phi_\alpha^4 \right) + \frac{L^d \tilde{\Delta}(n)}{8} \left( \sum_{\alpha=1}^{n} \phi_\alpha^2 \right)^2,
\]  

(3.3)

where \( \tilde{t}(n), \tilde{u}(n) \) and \( \tilde{\Delta}(n) \) will be presented bellow. With the help of the identity

\[
\exp \left( \frac{a A^2}{2} \right) = \frac{1}{(2\pi a)^{1/2}} \int_{-\infty}^{\infty} dy \exp[-(1/2a)y^2 + yA],
\]  

(3.4)

we get

\[
\mathcal{Z}_p^{\text{eff}}(n) = Tr_\phi \exp[\mathcal{H}_p^{\text{eff}}(n)] = \int_{-\infty}^{\infty} dy P_n(y) \left[ S_N \int_{0}^{\infty} d|\phi| |\phi|^{N-1} \exp(\mathcal{H}_r^{\text{eff}}(n)) \right]^n,
\]  

(3.5)

where

\[
\mathcal{H}_r^{\text{eff}}(n) = -\frac{1}{2} L^d \left[ \left( \tilde{t}(n) + \frac{y}{L^{d/2}} \right) |\phi|^2 + \frac{1}{12} \tilde{u}(n) |\phi|^4 \right]
\]  

(3.6)

is an effective Hamiltonian with a random variable \( y \) with Gaussian distribution (depending on \( \Delta(n) \))

\[
P_n(y) = \frac{\exp \left( -\frac{y^2}{2\Delta(n)} \right)}{\sqrt{2\pi \Delta(n)}}
\]  

(3.7)
and $S_N = \frac{2\pi^{N/2}}{\Gamma(N/2)}$ is the surface of a $N$-dimensional unit sphere.

Let us note that the above mentioned equivalence between the models (2.1) and (2.9) in the used approximation may be mathematically expressed, within the used approximation by the following relation:

$$F[\mathcal{H}_r] = -\frac{\partial}{\partial n} Z_p(n) \big|_{n=0}.$$  \hfill (3.8)

From Eqs. (3.5) and (3.8), and by using the identity

$$\frac{\partial}{\partial n} A^n(n) \big|_{n=0} = \ln A(0)$$  \hfill (3.9)

for the free energy, we get

$$F[\mathcal{H}_r] = -\int_{-\infty}^{\infty} dy P_0(y) \ln Z_r(0),$$  \hfill (3.10)

where

$$Z_r(0) = S_N \int_0^\infty d|\phi||\phi|^{N-1} \exp[\mathcal{H}_{r_{\text{eff}}}(0)]$$  \hfill (3.11)

is the partition function for the random system (3.6) after taking the limit $n \to 0$. The obtained effective “random-$T_c$ model” (3.6), distributed with Gaussian weight (3.7), is the analytic basis of this paper. The effective constants $\tilde{t}(n)$, $\tilde{u}(n)$ and $\tilde{\Delta}(n)$ involve $n$ and finite-size $L$ as parameters. For describing the finite-size properties of the initial model (2.1), as follows from Eqs. (3.10) and (3.11), it is necessary to set $n$ to zero. In the next sections we shall consider the results of this procedure.

**IV. THE FSS EXPRESSION FOR THE FREE ENERGY AND CUMULANTS IN THE ZERO MODE APPROXIMATION**

If we neglect the loop corrections this corresponds to the mean-field approximation. Then the zero mode playing the role of the uniform magnetization may be treated exactly. In this case the effective Hamiltonian (3.3) of the model reduces to

$$\mathcal{H}_{r_{\text{MF}}} = -\frac{1}{2} L^d \left[ t \sum_{\alpha=1}^n \phi_\alpha^2 + \frac{1}{12} u \sum_{\alpha=1}^n (\phi_\alpha^2)^2 - \frac{\Delta}{4} \left( \sum_{\alpha=1}^n \phi_\alpha^2 \right)^2 \right].$$  \hfill (4.1)

Now using an appropriate rescaling of the field $|\phi| = (u L^d)^{-1/4} \Phi$ and introducing the scaling variable

$$\mu = t L^{d/2} u^{-1/2},$$  \hfill (4.2)

for the partition function Eq. (3.11) in the mean-field approximation we obtain

$$Z_{r_{MF}}(0) = (u L^d)^{-N/4} I_N(\mu + y/u^{1/2}),$$  \hfill (4.3)
where we have introduced the following auxiliary function
\[ I_N(z) = S_N \int_0^\infty d\Phi \Phi^{(N-1)} \exp \left\{ -\frac{1}{2} \left[ z\Phi^2 + \frac{1}{12}\Phi^4 \right] \right\}. \]  
(4.4)

From Eqs. (3.10) and (4.3) we get for the free energy
\[ F[H_{MF}] = -\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dy \exp \left( -\frac{1}{2} \frac{y^2}{\Delta} \right) \ln \left[ (uL^d)^{-N/4} I_N \left( \mu + y/u^{1/2} \right) \right]. \]  
(4.5)

If we introduce a second scaling variable
\[ \lambda = \frac{\Delta}{u}, \]  
(4.6)
and using Eqs. (A4) (see appendix), Eq. (4.5) takes its final form
\[ F[H_{MF}] = -\frac{1}{\sqrt{2\pi \lambda}} \int_{-\infty}^{\infty} dx e^{-(x-\mu)^2/2\lambda} \ln \left[ D_{-N/2}(\sqrt{3}x) \right] - \frac{3}{4} (\lambda + \mu^2) + \frac{N}{4} \ln \left( \frac{uL^d}{12\pi^2} \right). \]  
(4.7)

For the Ising case \( N = 1 \) a similar expression for the quenched free energy in a slightly different context is obtained and its analytic structure is studied in references [27–29]. Obviously (4.7) is well defined for any positive \( \lambda \) and in the limit \( \lambda \to 0 \) we recover the well known result for the free energy of the pure model.

In addition to the free energy, one also needs to know the correlation functions. Within the replica method the averages of the fields \( \{\phi_\beta\} \) are defined by (see e.g. [12])
\[ \langle |\phi_\beta|^{2m} \rangle_{H_{MF}} = \lim_{n \to 0} \left[ \mathcal{Z}_{MF}^n(n)^{-1} S^n_N \int \left( \prod_{\alpha=1}^n d|\phi_\alpha| \right) (|\phi_\alpha|)^{N-1} (|\phi_\beta|)^{2m} \exp(H_{MF}^p) \right], \]  
(4.8)
where
\[ \mathcal{Z}_{MF}^n(n) = S^n_N \int \left( \prod_{\alpha=1}^n d|\phi_\alpha| \right) (|\phi_\alpha|)^{N-1} \exp(H_{MF}^p). \]  
(4.9)

Note that the final result must be independent of replica index \( \beta \), because \( H_{MF}^p \) is invariant under permutation of the replicas. After taking the limit \( n \to 0 \), we end with the following expression:
\[ \overline{M}_{2m} := \langle |\phi_\beta|^{2m} \rangle_{H_{MF}} = \frac{(uL^d)^{-m/2}}{\sqrt{2\pi \lambda}} \int_{-\infty}^{\infty} dx \frac{I_{N+2m}(x)}{I_N(x)} e^{-(x-\mu)^2/2\lambda}. \]  
(4.10)

In a similar way
\[ \langle \overline{M}_2 \rangle^2 := \langle |\phi_\alpha|^2 |\phi_\beta|^2 \rangle_{H_{MF}} = \frac{(uL^d)^{-1}}{\sqrt{2\pi \lambda}} \int_{-\infty}^{\infty} dx \left[ \frac{I_{N+2}(x)}{I_N(x)} \right]^2 e^{-(x-\mu)^2/2\lambda}. \]  
(4.11)

From Eqs. (4.10) and (4.11), when \( \mu = 0 \) and \( N = 1 \) we obtain the results of Ref. [6].
In terms of the normalized magnetization $\mathcal{M}$ the susceptibility is given as
\[ \chi = L^d \mathcal{M}_2. \quad (4.12) \]

Another quantities of importance for numerical analysis is the Binder cumulant defined by
\[ B = 1 - \frac{1}{3} \frac{\mathcal{M}_4}{\mathcal{M}_2^2}, \quad (4.13) \]

and the cumulant, specific for the random system defined as
\[ R = \frac{(\mathcal{M}_2)^2 - \mathcal{M}_4^2}{\mathcal{M}_2^2}. \quad (4.14) \]

Since the parameter $R$ is the relative variance of the observable (the susceptibility), as we said in the Introduction, it is a measure of the self-averaging in the random system. If self-averaging takes place this quantity should be zero in the thermodynamic limit.

**V. FINITE-SIZE SHIFT OF $T_c$ : LOWEST ORDER IN $\epsilon$**

The perturbatively calculated parts of the free energy and cumulants, which contain contributions of all nonzero modes, depend, to one-loop order, on the shift of the critical temperature and on the renormalized coupling constants $u$ and $\Delta$. The application of the finite-size $\epsilon$-expansion to the model system (2.9) requires the corresponding renormalization constants.

To one loop order, using the minimal subtraction scheme, before taking the $n \to 0$ limit, we obtain:
\[
Z_t = 1 + \frac{N + 2}{6\epsilon} \hat{u} - \frac{2 + nN}{2\epsilon} \hat{\Delta}, \quad (5.1a)
\]
\[
Z_u = 1 + \frac{\hat{u}}{6\epsilon} - \frac{6\hat{\Delta}}{\epsilon}, \quad (5.1b)
\]
\[
Z_\Delta = 1 + \frac{N + 2}{3\epsilon} \hat{u} - \frac{8 + nN}{2\epsilon} \hat{\Delta}. \quad (5.1c)
\]

In Eqs. (5.1),
\[
\hat{u} = u \left( \frac{2}{(4\pi)^{d/2} \Gamma(d/2)} \right), \quad (5.2a)
\]
\[
\hat{\Delta} = \Delta \left( \frac{2}{(4\pi)^{d/2} \Gamma(d/2)} \right). \quad (5.2b)
\]

The $\beta$ functions associated to $\hat{u}$ and $\hat{\Delta}$ have the form
\[
\beta_u = -\hat{u} \epsilon + \frac{N + 8}{6} \hat{u}^2 - 6\hat{u}\hat{\Delta}, \quad (5.3a)
\]
\[
\beta_\Delta = -\hat{\Delta} \epsilon - \frac{8 + nN}{2} \hat{\Delta}^2 + \frac{N + 2}{3} \hat{u}\hat{\Delta}. \quad (5.3b)
\]
The fixed points of this system first have been studied in [30] and for the purposes of the impurity problem in [17]. The values of \( \hat{u} \) and \( \hat{\Delta} \) in the fixed point, interesting in the random case, are

\[
\hat{u}^*(n) = \frac{6(4-nN)}{16(N-1)-nN(N+8)} \epsilon, \tag{5.4a}
\]

\[
\hat{\Delta}^*(n) = \frac{2(4-N)}{16(N-1)-nN(N+8)} \epsilon. \tag{5.4b}
\]

The corresponding expression for the exponent \( \nu \) up to the first order of \( \epsilon \), is:

\[
\frac{1}{\nu(n)} = 2 - \frac{6N(1-n)}{16(N-1)-nN(N+8)} \epsilon. \tag{5.5}
\]

It should be noted here that we shall consider \( N \)-component fields with \( 1 < N < N_c(d) \), where \( N_c(d) = 4 - 4\epsilon + \mathcal{O}(\epsilon^2) \) is the critical number of spin components that defines the stability of the random fixed point in the \( n = 0 \) limit. The stability of the different fixed points of the model has been also considered in [31]. The analysis of the Ising case \( (N = 1) \) needs to perform a loop expansion to second order (see Introduction) and is beyond the scope of the present study.

As it was explained above, the loop corrections will be treated perturbatively on the nonzero \( k \) modes. In the lowest order in \( \epsilon \), this procedure generates a shift of the critical temperature \( t \to \tilde{t}(n) \);

\[
\tilde{t}(n) = tZ_t + t_L, \tag{5.6}
\]

where the term \( tZ_t \) is coming from the one-loop counterterm (see (5.1)), and

\[
t_L = \left[ \frac{N+2}{6} \hat{u} - \frac{2+Nn}{2} \hat{\Delta} \right] \frac{1}{L^d} \sum_k \frac{1}{k^2 + t} \tag{5.7}
\]

is the finite-size correction. The two diagrammatic contributions for \( t_L \) are shown in FIG. 1. Both diagrams from the \( u \) and the \( \Delta \) contributions differ only by their numerical factors. The prime in the \( d \)-fold sum in the above equations denotes that the term with a zero summation index has been omitted.

After some algebra (details for the pure case \( (\Delta = 0) \) see in [13]), near the upper critical dimension \( d = 4 - \epsilon \), we obtain

\[
\tilde{t}(n) = t + \left[ \frac{N+2}{12} \hat{u} - \frac{2+Nn}{4} \hat{\Delta} \right] \left( t \ln t + 4L^{-2}F_{4,2}(tL^2) \right), \tag{5.8}
\]

where

\[
F_{d,2}(x) = \int_0^\infty dz \exp \left( -\frac{xz}{(2\pi)^2} \right) \left[ \left( \sum_{\ell=-\infty}^{\infty} e^{-\ell^2} \right)^d - 1 - \left( \frac{x}{\pi} \right)^{d/2} \right], \tag{5.9}
\]

Some particular values of the constant \( F_{d,2}(0) \) and a method of calculation are given in [32].
At the fixed point $\hat{u} = \hat{u}^*(n)$, $\hat{\Delta} = \hat{\Delta}^*(n)$, up to the first order in $\epsilon$, the terms proportional to $\ln L$ cancel and Eq. (5.8) can be written in the following scaling form
\[
\tilde{t}(n)L^2 = y - \frac{3(n - 1)N}{16(N - 1) - nN(N + 8)} [y \ln y + 4F_{4,2}(y)] \epsilon, \tag{5.10}
\]
where the scaling variable $y = tL^{1/\nu(n)}$ has been introduced.

In the $n = 0$ limit, the expression for the exponent measuring the divergence of the correlation length is [16,17]:
\[
\frac{1}{\nu_R} \equiv \frac{1}{\nu(0)} = 2 - \frac{3N}{8(N - 1)} \epsilon, \tag{5.11}
\]
instead of the critical exponent for the pure case
\[
\frac{1}{\nu} = 2 - \frac{N + 2}{N + 8} \epsilon. \tag{5.12}
\]
The scaling form (5.10) can be written for this case as
\[
\tilde{t}(0)L^2 = y + \frac{3N}{16(N - 1)} [y \ln y + 4F_{4,2}(y)] \epsilon, \tag{5.13}
\]
where $y = tL^{1/\nu_R}$.

From the above expression one can obtain the large-$L$ asymptotic form of the $T_c(\infty)$ shift, i.e.
\[
T_c(L) - T_c(\infty) \sim L^{-1/\nu_R}. \tag{5.14}
\]
In Eq. (5.14), $T_c(L) := T_c(\varphi, L)$ denotes the average pseudo critical temperature ($T_c(\varphi, L)$ is pseudo critical temperature for a specific random realization $\varphi(x)$) and $T_c(\infty) = \lim_{L \to \infty} T_c(L)$. Eq. (5.14) was suggested in [2]. Combined with the phenomenological FSS theory it gave rise to the lack of SA, and is confirmed by numerical studies (see [4]). Here it is verified independently and directly.

VI. RENORMALIZATION OF THE COUPLING CONSTANTS: LOWEST ORDER IN $\epsilon$

We perform the renormalization in a similar way also for $\tilde{u}(n)$ and $\tilde{\Delta}(n)$ by taking into account the diagrammatic contributions, from $u$ and $\Delta$ shown in FIG. [2]. The result is
\[
\tilde{u}(n) = uZ_u + u_L \tag{6.1a}
\]
\[
\tilde{\Delta}(n) = \Delta Z_\Delta + \Delta_L, \tag{6.1b}
\]
where $uZ_u$ and $\Delta Z_\Delta$ are the one-loop counterterms for the coupling constants, and
are the corresponding finite-size corrections. As one can see the summand in Eq. (6.2a) can be expressed as the first derivative of the summand of Eq. (5.7) with respect to \( t \). So, at the fixed point, algebraic transformations similar to those performed in the previous section lead to

\[
\tilde{u}^*(n)L^\epsilon = u^*(n) \left[ 1 + \frac{1}{2}(1 + \ln y)\epsilon + 2\epsilon F^\prime_{4,2}(y) \right],
\]

\[
\tilde{\Delta}^*(n)L^\epsilon = \Delta^*(n) \left[ 1 + \frac{1}{2}(1 + \ln y)\epsilon + 2\epsilon F^\prime_{4,2}(y) \right],
\]

where the prime indicates that we have derivative of the function \( F_{4,2}(y) \) with respect to its argument.

The results for the disordered system simply follow by setting \( n = 0 \). From the results for the shift of the critical temperature (5.10) and the renormalization of the coupling constant \( u \), given by Eq. (5.3a), we reproduce the results for the pure FSS case, by setting \( \Delta = 0 \) and \( n = 0 \). Moreover, this result still holds even if we find the FSS corrections after the analytical continuation to \( n = 0 \), expressing the commutativity of the problem.

VII. VERIFICATION OF FSS

Let us consider the scaling variables

\[
\mu(n) = \tilde{\epsilon}(n)L^{d/2}/\sqrt{\tilde{u}(n)}, \quad \lambda(n) = \tilde{\Delta}(n)/\tilde{u}(n).
\]

At the fixed point they can be expressed in terms of scaling variable \( y = tL^{1/\nu(n)} \):

\[
\mu^*(n) = \frac{1}{\sqrt{u^*(n)}} \left\{ y - \frac{1}{4} y \left[ 1 + \frac{(4 - N)(4 - nN)}{16(N - 1) - nN(N + 8)} \ln y \right] \epsilon 
- \frac{12N(n - 1)}{16(N - 1) - nN(N + 8)} F_{4,2}(y)\epsilon - yF^\prime_{4,2}(y)\epsilon \right\}
\]

and

\[
\lambda^*(n) = \frac{4 - N}{3(4 - nN)}.
\]

In the limit \( n = 0 \), Eqs. (7.2) and (7.3) yield the following scaling variables describing the disordered system (2.1):

\[
\mu^* := \mu^*(0) = \frac{1}{\sqrt{u^*(0)}} \left\{ y - \frac{1}{4} y \left[ 1 + \frac{4 - N}{4(N - 1)} \ln y \right] \epsilon 
+ \frac{3N}{4(N - 1)} F_{4,2}(y)\epsilon - yF^\prime_{4,2}(y)\epsilon \right\}.
\]
where \( y = tL^{1/\nu_R} \), and
\[
\lambda^* := \lambda^*(0) = \frac{4 - N}{12}.
\] (7.5)

These equations verify the finite-size scaling hypotheses and show that we are really dealing with a one-variable problem, since the second variable \( \lambda^* \) is a fixed universal number. At the critical point \( t = 0 \), since the constant \( F_{4,2}(0) = -8 \ln 2 \), see Ref. [32], we have
\[
\mu_0^* := \mu^*|_{t=0} = -\frac{N \ln 2}{\pi} \sqrt{\frac{3\epsilon}{N - 1}}.
\] (7.6)

Numerical values for different thermodynamic quantities can be obtained with the help of Eqs. (7.5) and (7.6). Note that the scaling variable \( \mu_0^* \) is proportional to \( \sqrt{\epsilon} \). Consequently all the \( \epsilon \)-expansion results will be expressed in power of \( \sqrt{\epsilon} \) as it was the case for the pure systems (see [13] for example).

**VIII. CUMULANTS AND SELF-AVERAGING**

In Ref. [4], the Binder cumulant \( B \) and the the relative variance \( R \) (Eqs. (4.13) and (4.14)) are calculated analytically and numerically at the critical point \( T = T_c \) in the asymptotic regime \( \lambda \simeq 1/4 \) for \( N = 1 \) and \( d = 4 \). In ref. [33] (see also [4]), the same quantities were calculated numerically for \( N = 1 \) and \( d = 3 \). In both cases the results showing that the system exhibits a lack of SA.

In the remainder of this section we concentrate on the calculation of the cumulants \( B \) and \( R \) (4.13) and (4.14) in cases \( d \geq 4 \) and \( d = 4 - \epsilon \). The meaning to consider the case \( d \geq 4 \) is in its simple analytical nonperturbative treatment. Although the results based on the \( \epsilon \)-expansion give only a qualitative description of the three dimensional physics, we hope that they shed some light at least on the applicability of the theory for studying diluted models.

Let us first note that if \( 1 < N < 4 \) and \( d = 4 - \epsilon \), the case under consideration applies to the situation (see Eq. (5.11)) where \( \nu_R > 2/d \) and randomness is relevant (R-case). Up to the first order in \( \epsilon \), due to the RG arguments, no SA must be expected near the critical point [2]. This statement is supported also by our RG calculations. In Table I and Table II we present the corresponding universal numbers for \( B \) and \( R \) at \( d \geq 4 \) and \( d = 3 \) in the region \( Lt^{\nu_R} = \frac{L}{\xi} \ll 1 \), i.e. in the vicinity of the critical point. The calculations are performed with variable \( \mu = 0 \) for \( d \geq 4 \) and \( \mu = \mu_0^* \) from Eq. (7.6) (setting \( \epsilon = 1 \)) for \( d = 3 \), and with variable \( \lambda \) taken from Eq. (7.3) in both cases. The asymptotic behavior for small \( \mu \) is presented in the Appendix. The numerical values of \( B \) and \( R \) in the random case and for \( N = 1 \), presented in Table I, are in full agreement with those obtained in Ref. [33], while those of \( B \) for the pure case and \( N = 1 \) (Table I and Table II) are in full agreement with Ref. [13].

The random case \( N = 1 \) for \( d < 4 \) can not be considered within the present expansion, because of the apparent divergence of \( \mu_0^* \) that takes place to the used order in \( \epsilon \). Up to now there are only numerical values \( B = \frac{2}{3} \), \( g_4 = 0.448 \) and \( R = g_2 = 0.150(7) \) obtained in [33] through Monte Carlo simulations. What is possible to calculate here are the corresponding
values of B and R very close to \(N = 1\), e.g. for \(N = 1.001\). For completeness these results are presented in Table II. More general, one can see that if \(N \to 1\), then \(B \to \frac{2}{3}\) and \(R \to 0\), i.e. the system exhibits SA. This evident discrepancy with the reality is due to the wrong assumption that some information about the random case \(N = 1\) can be obtained from the above formulas in this limiting case. As it was pointed out the correct treatment of the case \(N = 1\) seems to be a more difficult computational problem.

The finite size correction to the bulk critical behavior of the cumulants \(B\) and \(R\) in the region \(Lt^{1/2}r = \frac{\mu}{\xi} \gg 1\), i.e. away from the critical point, are obtained with the help of the asymptotics \(\mu \gg 1\), given in the Appendix (Eqs. 8.1, 8.2). According to the analysis presented there, we obtain for Binder’s cumulant

\[
B = 1 - \frac{1}{3} \left(1 + \frac{2}{N}\right) \left(1 + 3\frac{\lambda - 1}{3\mu^2}\right) + \mathcal{O}\left(\frac{1}{\mu^3}\right). 
\]  

(8.1)

For the cumulant \(R\) we get

\[
R = \frac{\lambda}{\mu^2} + \mathcal{O}\left(\frac{1}{\mu^3}\right). 
\]  

(8.2)

The final results can be obtained by replacing \(\lambda\) and \(\mu\) by their respective expressions evaluated at the fixed points of the model given in Eqs. (7.4) and (7.5). So, to the lowest order in \(\epsilon\), we have

\[
B = 1 - \frac{1}{3} \left(1 + \frac{2}{N}\right) + \mathcal{O}\left(\frac{\xi}{L}\right). 
\]  

(8.3)

and

\[
R = \frac{4 - N}{8(N - 1)} \epsilon \left(\frac{\xi}{L}\right)^4 + \mathcal{O}\left(\frac{\xi^5}{L^5}\right). 
\]  

(8.4)

It is interesting to compare Eq. (8.1) with the corresponding result for the pure system

\[
B_{\text{pure}} = 1 - \frac{1}{3} \left(1 + \frac{2}{N}\right) \left(1 - \frac{1}{3\mu_p^2} + \mathcal{O}\left(\frac{1}{\mu_p^3}\right)\right). 
\]  

(8.5)

Up to the lowest order in \(\frac{1}{\mu}\) they coincide for \(1 < N < 4\), moreover for \(N = 4 - \delta\) (with \(\delta \ll 1\)), we have \(\mu = \mu_p + \mathcal{O}(\epsilon\delta)\) and \(B = B_{\text{pure}} + \mathcal{O}(\epsilon\delta)\). The result (8.4) confirms the statement [2] that away from the critical point, a strong SA emerges in the system, as \(R \to 0\) with \(\frac{L}{\xi} \gg 1\).

**IX. CONCLUSIONS**

In the present paper we propose a general scheme for the FSS scaling analysis of a finite disordered \(\mathcal{O}(N)\) system. The method, we use here, is an extension of the field theoretical
methods used to analyse FSS properties in pure systems. The nature of the symmetry (obtained as a consequence of the use of the replica trick, which removes the disorder) of the model complicates the perturbative structure of the theory in comparison with the corresponding $\mathcal{O}(N)$ pure one. Remind that, the final results for the disordered system are obtained by making the number of replicas vanishing. Our results concern mainly systems with number of components larger than 1 i.e. non Ising systems. Their extension to Ising systems requires higher loop calculations, because of the degeneracy of the one loop order RG equations.

Our main results are related to the formulation of the problem for some number of components $N$ of the fluctuating field for dimensions $d > 4$ and $d = 4 - \epsilon$. Due to the presence of randomness, it is shown that we are dealing with two variables problem with scaling variables $\mu = t L^{d/2} u^{-1/2}$ and $\lambda = \Delta / u$. In the mean field regime $d > 4$ our results are a generalization for $N > 1$ of those obtained in [6] for $N = 1$. Evaluating numerically the corresponding analytic expressions for the Binder’s cumulant $B$ and the relative variance $R$, we demonstrate a monotonic increase of $B$ as a function of $N$ in both pure and random cases and a monotonic decrease of $R$ (to zero for $N = 4$) in the random case (see Table I).

The $\epsilon$-expansion to first order in $\epsilon$, shows that close to the critical temperature, one can express the physical observables, the shift of the critical temperature and the renormalization of the coupling constants in terms of $\mu$ and $\lambda$. In the random fixed point the parameter $\lambda$ takes an universal value (see equation (7.5)). It is found that the distance, over which the bulk critical temperature is shifted, is proportional to $L^{1/\nu R}$, in agreement with the statement of Ref. [2]. This result, combined with phenomenological FSS, gives rise to the lack of SA. The scaling parameters $\mu$ and $\lambda$, also enter in the final expression for the Binder cumulant (4.13) and the relative variances (4.14), giving explicit expressions for them in the different asymptotic regimes. The numerical calculation of the above parameters permits also the verification of the FSS and SA (see Table I). The last is shown to be absent in the regime $\nu R > 2/d$, where randomness are relevant and our analysis explicitly shows that in this regime the relative variance is always non-zero for the case of stability of the RG solutions, i.e. $1 < N < 4$ and $d = 4 - \epsilon$.

One can also try to repeat the analysis without the use of the replica-trick. For this aim, one needs to define in a proper way the procedure in the zero-mode approximation, when rescaling the random part of the Hamiltonian for finite system. One can realize that this is the $k = 0$ part of this term, which will give a contribution to the free-energy. This scheme permits formally to end with the same expressions for the shift of the critical temperature and the renormalization constants, as we did within the replica formalism.

In our opinion, the present FSS study can be also applied in the “canonical” case [3], where the disorder is characterized by a constant total number of the occupied sites (or bonds), instead of the constant average density. We hope that results, similar to the bulk case, will also hold in the case of finite geometry, relating in this way our theoretical findings with the Monte-Carlo simulations.

APPENDIX: FINITE-SIZE SCALING BEHAVIOR OF THE EVEN MOMENTS OF THE ORDER PARAMETER

In this Appendix we present the mathematical details of how to obtain the asymptotic of the averages:

\[
M_{2m} = \frac{2L^d}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dx \frac{\mathcal{I}_{N+2m}(\mu + \sqrt{\lambda} x)}{\mathcal{I}_{N}(\mu + \sqrt{\lambda} x)} e^{-x^2/2}, \tag{A1a}
\]

\[
\langle M_2 \rangle^2 = \frac{2L^d}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dx \left[ \frac{\mathcal{I}_{N+2}(\mu + \sqrt{\lambda} x)}{\mathcal{I}_{N}(\mu + \sqrt{\lambda} x)} \right]^2 e^{-x^2/2}, \tag{A1b}
\]

where we have introduced the function

\[
\mathcal{I}_N(z) = S_N \int_0^\infty d\Phi \Phi^{(N-1)} \exp \left\{ -\frac{1}{2} \left[ z\Phi^2 + \frac{1}{12} \Phi^4 \right] \right\}. \tag{A2}
\]

The integral in the definition of function \( \mathcal{I}_N(z) \) given by Eq. \( \text{(A2)} \), may be evaluated in terms of parabolic cylinder functions \( D_p(z) \) using the identity \( \text{[35]} \)

\[
\int_0^\infty x^{\nu-1} e^{-\beta x^2 - \gamma x} dx = (2\beta)^{-\nu/2} \Gamma(\nu) \exp\left(\frac{\gamma^2}{4\beta}\right) D_{-\nu}\left(\frac{\gamma}{\sqrt{2\beta}}\right). \tag{A3}
\]

The result is:

\[
\mathcal{I}_N(z) = (12\pi^2)^{N/4} \exp\left(\frac{3z^2}{4}\right) D_{-N/2}(\sqrt{3}z). \tag{A4}
\]

Now the above integrand in Eq. \( \text{(A1a)} \) can be rewritten in a very simple form

\[
\mathcal{M}_{2m}(x) := \frac{\mathcal{I}_{N+2m}(\mu + \sqrt{\lambda} x)}{\mathcal{I}_{N}(\mu + \sqrt{\lambda} x)} = \left(12\pi^2\right)^{\frac{m}{2}} \frac{D_{-m-N/2}(\mu + \sqrt{\lambda} x)}{D_{-N/2}(\mu + \sqrt{\lambda} x)\sqrt{3}}. \tag{A5}
\]

For small \( \mu \ll 1 \) (i.e. in the vicinity of the critical point) the asymptotic form of the ratio \( \text{(A5)} \) is given by

\[
\mathcal{M}_{2m}(x) = \left(12\pi^2\right)^{\frac{m}{2}} \left\{ \frac{D_{-m-N/2}(x\sqrt{3}\lambda)}{D_{-N/2}(x\sqrt{3}\lambda)} \right. \\
+ \frac{\mu \sqrt{3}}{2} \left[ \frac{D_{-N/2-1}(x\sqrt{3}\lambda)D_{-m-N/2}(x\sqrt{3}\lambda)}{(D_{-N/2}(x\sqrt{3}\lambda))^2} - \left(2m + N\right) \frac{D_{-m-N/2-1}(x\sqrt{3}\lambda)}{D_{-N/2}(x\sqrt{3}\lambda)} \right] \\
+ O(\mu)^2 \right\}. \tag{A6}
\]
In the mean-field regime and at the critical point we have \( \mu = 0 \) and \( M_{2m} \) is equal to the first term in the r.h.s. of Eq. (A6).

For large \( \mu \gg 1 \), the asymptotic behavior of the ratio \( M_{2m} \) is obtained with the help of the well known Watson's Lemma:

**Lemma:** (see for example [36])

Suppose \( \alpha > 0, \beta > 0 \) and \( f(x) \) an analytic function in a neighborhood of \( x = 0 \),

\[
\begin{align*}
f(x) &= \sum_{k=0}^{\infty} \frac{f^{(k)}(0)}{k!} x^k, \quad |x| < R, \\
|f(x)| &\leq c_1 e^{c_2 x^\alpha}, \quad x \in [R, X],
\end{align*}
\]

for positive constants \( c_1, c_2 \). Then:

\[
\int_{0}^{X} x^{\beta-1} e^{-sx^\alpha} f(x) dx \sim \frac{1}{\alpha} \sum_{k=0}^{\infty} s^{-(k+\beta)/\alpha} \Gamma \left( \frac{k+\beta}{\alpha} \right) \frac{f^{(k)}(0)}{k!},
\]

as \( s \to \infty \) in the sector \( |\arg s| < \frac{\pi}{2} \).

According to this Lemma, from Eqs. (A2) (with \( z = \mu + x\sqrt{\lambda} \)) and (A5), we have

\[
M_2(x) = \left( 12\pi^2 \right)^{1/2} \frac{N}{\mu} \left[ 1 - \frac{x\sqrt{\lambda}}{\mu} + \frac{6x^2 \lambda - N - 2}{6\mu^2} + \mathcal{O} \left( \frac{1}{\mu^3} \right) \right] \quad (A7)
\]

and

\[
M_4(x) = 12\pi^2 \frac{N(N+2)}{\mu^2} \left[ 1 - \frac{2x\sqrt{\lambda}}{\mu} + \frac{9x^2 \lambda - N - 3}{3\mu^2} + \mathcal{O} \left( \frac{1}{\mu^3} \right) \right]. \quad (A8)
\]

Using the asymptotic of \( M_2 \) and \( M_4 \) for large \( \mu \), we can get the behavior of the cumulants \( R \) and \( B \) in both cases \( d \geq 4 \) and \( d = 4 - \epsilon \). They are given by

\[
B = 1 - \frac{1}{3} \left( 1 + \frac{2}{N} \right) \left[ 1 + \frac{3\lambda - 1}{3\mu^2} \right] + \mathcal{O} \left( \frac{1}{\mu^3} \right). \quad (A9)
\]

For the cumulant \( R \) we get

\[
R = \frac{\lambda}{\mu^2} + \mathcal{O} \left( \frac{1}{\mu^3} \right). \quad (A10)
