INTRODUCTION

Ovarian cancer is the one of the most common cancer of the female reproductive system (1, 2). Despite surgery and chemotherapy for treatment of patients with advanced ovarian cancer, five-year survival rates were reported to be 36% and 8% for stage III and stage IV, respectively (1, 2). Chemotherapy is one of the most common strategies for cancer treatment. Anti-cancer agents inhibit the division of rapidly growing cells, which is a characteristic of the cancerous cells. Paclitaxel (Taxol®) is widely used as a chemotherapy agent for the treatment of various cancers such as metastatic breast cancer, advanced ovarian cancer, and non-small cell lung cancer (3, 4).

The tubular/microtubular system is suggested as an intercellular target for paclitaxel (5). But, the exact mechanism of the cytotoxicity of paclitaxel against tumor cells is still under investigations. Yeung et al. proposed that paclitaxel-induced cell death occurs through two modes, apoptosis at low concentration and necrosis at high concentration (6).

Paclitaxel induces necrosis and apoptosis in human endothelial cells (7). Paclitaxel is used an effective anti-neoplastic agent on various cancers, especially ovarian cancer (3). Paclitaxel causes necrotic area in ovarian tumor xenografts in animal (8). Current standard diagnostic techniques for staging of ovarian cancer are measuring the level of CA-125 (Mucin 16) in serum and ultrasonography (9).

Because of the deficiency of medical diagnostics tools in early detection of disease, most patients with ovarian cancer have advanced disease at the time of diagnosis (10). For patient who progresses on cancer treatment, the efficacy of paclitaxel should be monitored during the therapy. For this reason, for planning and following-up of treatment in many cancers, 18F-fluorodeoxyglucose (18F-FDG) as positron emission tomography (PET) is used for monitoring of cancer treatment; it has sensitivity of 91% and specificity of 88% (11).

ABSTRACT

Objectives: The monitoring of cancer treatment response to chemotherapy is considered an essential strategy for follow-up of patients. The aim of this study was to evaluate the use of 99mTc-glucarate as a radiotracer for in vivo quantification and visualization of necrotic area and therapeutic effect of paclitaxel in ovarian cancer xenografted nude mice.

Materials and Methods: After implantation of human ovarian cancer (SKOV-3) in nude mice, tumor xenografted mice were enrolled in two groups as control and treatment (paclitaxel) groups. 99mTc-glucarate uptakes were quantified in tumors of control and treatment groups and also tumor imaging was performed with a gamma camera. The necrotic and viable areas of tumor and tumoral masses were evaluated through histopathological and macroscopic observations, respectively.

Results: 99mTc-glucarate uptake in tumor of treatment group was higher than control group. 99mTc-glucarate uptake in ovarian tumor was clearly visualized with gamma imaging in both groups, but paclitaxel treated group showed higher radioactive uptake than control mice. The necrotic area in tumoral mass of mice treated with paclitaxel was confirmed by histopathological observations.

Conclusion: 99mTc-glucarate is an effective radiotracer for evaluation and monitoring of tumor necrosis caused by chemotherapy, and it may be helpful for therapy monitoring in patients with cancer.

Due to high cost and low accessibility in many areas of the world, the use of $^{18}$F-FDG is limited; therefore, it is necessary to find a substitute technique and proper radiopharmaceutical agent instead of $^{18}$F-FDG (12). $^{99m}$Tc-glucarate has been used as a radiopharmaceutical agent for imaging of myocardial infarction (13, 14), acute cerebral injury (15) and in tumors (16-18). Accumulation of $^{99m}$Tc-glucarate in normal and apoptotic cells is less than necrotic cells (19). Glucarate is a metabolite of D-glucuronic acid as a natural product, which has low molecular weight with six-carbon dicarboxylic acid structure that could be labeled with $^{99m}$Tc (20). $^{99m}$Tc-glucarate could be used in single-photon emission computed tomography (SPECT) that is more cost-effective and accessible than $^{18}$F-FDG (12). The aim of this study was to evaluate the use of $^{99m}$Tc-glucarate in the assessment of necrotic area and therapeutic effect of paclitaxel in ovarian cancer xenografted nude mice. The results of $^{99m}$Tc-glucarate uptake and tumor imaging were compared with pathological data.

Materials and Methods

Glucaric acid (D-saccharic acid potassium salt) was purchased from Sigma (USA). Paclitaxel was purchased from Sobhan Oncology Company (Rasht, Iran). The $^{99m}$TcO$_4$Na was eluted from a $^{99m}$Mo/$^{99m}$Tc radionuclide generator (Parsisotope, Tehran, Iran). Radiochemical purity was assayed with instant thin layer chromatography (ITLC). The distribution of radioactivity on the ITLC strips was quantized using a Lablogic mini-scan TLC scanner and analyzed with Laura image analysis software (Sheffield, UK). Radioactivity in the samples was measured using a NaI(Tl) gamma detector (Delshid, Iran).

Preparation of $^{99m}$Tc-glucarate

$^{99m}$Tc-glucarate was prepared according to a method that was previously published by Babbar and Sharma with minor modifications (21). The single-vial compositions were 12 mg mono potassium glucarate, 0.1 mg SnCl$_2$·2H$_2$O, and sodium bicarbonate in saline. $^{99m}$Tc-glucarate was obtained after adding about 278 MBq of $^{99m}$TcO$_4$Na to vial (pH 8). The mixture was shaken for one minute and allowed to react at room temperature for 20 min. Then, 200 µl HCl (0.1 N) was added to mixture for adjusting pH to 7-7.5. Radiochemical purity (RCP) was determined by ITLC strips developed in 0.9% saline and methyl ethyl ketone (MEK). In the ITLC strip developed by saline, $^{99m}$Tc-colloid remained at the origin while $^{99m}$Tc-glucarate and free $^{99m}$Tc migrated at the solvent front. In the ITLC strip developed by MEK, $^{99m}$Tc-glucarate remained at the origin while the free $^{99m}$Tc was at the solvent front.

Tumor model

All animal experiments were approved by Research and Ethical Committee of Mazandaran University of Medical Sciences, Sari, Iran. The study was performed on female nude mice bearing human ovarian tumor (SKOV-3). SKOV-3 cell line was purchased from the Pasteur Institute of Iran (Tehran, Iran) and cultured in Dulbecco’s Modified Eagle’s medium (DMEM) medium supplemented with 10% fetal bovine serum (FBS) and penicillin–streptomycin (Gibco, Grand Island, NY) at 37 °C in a humidified environment and 5% CO$_2$. Female nude mice (3 to 5-week-old, 14-18 g) (Institute Pasteur, North Branch, Amol, Iran) were inoculated subcutaneously in the right hind leg with SKOV-3 cells $(1×10^3)$ in 100 µl of complete DMEM. After 48 hrs of tumor implantation, all the tumor-bearing mice were divided randomly into two groups as control and treatment groups. As soon as the tumor was palpable (0.25 mm$^3$), the tumor measuring was started and it was stated as day 1. Paclitaxel treatment was started when the tumor volume of the mice reached 200–250 mm$^3$ (on day 14 after tumor inoculation). Tumor sizes were measured every day to evaluate the antitumor efficacy of paclitaxel. Tumor-bearing mice were received intraperitoneally paclitaxel (40 mg/kg total dose over 2 duration or 20 mg/kg drug on a q7d×2 schedule). Control animals were received normal saline in same manner to treatment group.

Tumor measurements were made using a vernier caliper while mice were conscious and were calculated according to formula as a standard practice (tumor volume = $xy^2$/2). The length ($x$) is considered to be equivalent to the greatest longitudinal diameter and this considered to be equivalent to the greatest transverse diameter (22, 23).

Biodistribution

$^{99m}$Tc-glucarate was injected into the tail vein of both groups (treatment and control) of mice bearing tumors. The mice were sacrificed at 30 min post-injection. Blood and samples from the lung, liver, spleen, salivary gland, stomach, kidney, muscle, bone and tumor were dissected and weighed, and their radioactivities were measured. The tissue uptake values were calculated as percent of injected dose per gram tissue (%ID/g).

---

**Figure 1.** Tumor size changes in nude mice bearing human ovarian tumor in control group and following injection of paclitaxel treatment group (n = 4)
**Tumor gamma camera imaging**

Planar imaging studies were carried out with anesthetized SKOV-3 tumor-bearing mice to acquire a visual confirmation of the tumor uptake. Images were acquired at 30 min post-injection of $^{99m}$Tc-glucarate using an E-CAM dual head (Siemens Medical Solutions, Germany) equipped with a low energy high-resolution collimator.

**Histological analysis**

The tumoral specimens were fixed in 10% formalin, processed routinely, embedded in paraffin, sectioned at 5 μm, deparaffinized and stained with hematoxylin-eosin (H&E). Slides from each group were investigated by an observer blinded to the treatments. An Olympus microscope at × 20 magnifications was used to evaluate the effect of paclitaxel on cell density, necrosis, fibrosis and neovascularization.

**Statistical analysis**

Data were statistically analyzed using Excel software (Microsoft office, USA) using unpaired t-test. For all tests, $P$-values less than 0.05 were considered significant.

**Results**

**Preparation of $^{99m}$Tc-glucarate**

$^{99m}$Tc-glucarate was obtained with a radiochemical purity more than 98% (n = 10) (Supplementary Figure S1 and S2). The stability of $^{99m}$Tc-glucarate was assessed in normal saline and it was 98% ± 0.03 up to 4 hr (Supplementary Figure S3).

**Tumor growth and paclitaxel therapy**

Nude mice bearing ovarian tumor were injected with paclitaxel on day 14 after tumor sizes were 200 – 250 mm$^3$ (Figure 1). Tumor sizes were increased rapidly in control group, while paclitaxel treatment resulted in tumor growth inhibition ($P < 0.05$). At the end of 11 day of paclitaxel therapy, $^{99m}$Tc-glucarate was injected and animal biodistribution was conducted. At this time, the result of tumor growth experiment showed that paclitaxel inhibited tumor growth in animal.

**Biodistribution of $^{99m}$Tc-glucarate**

Biodistribution data in nude mice bearing ovarian tumor at 30 min post-injection of $^{99m}$Tc-glucarate are presented in Table 1. The tumor uptake of $^{99m}$Tc-glucarate was higher than muscle uptake in both groups of control and paclitaxel treatment. Tumor uptake of the $^{99m}$Tc-glucarate was higher in necrotic tumors ($4.71 ± 0.9\% \text{ ID/g}$) than in control tumors ($3.05 ± 0.4\% \text{ ID/g}$) ($P < 0.05$). The tumor-blood ratio was $0.7 ± 0.1\% \text{ ID/g}$ and $0.93 ± 0.4\% \text{ ID/g}$ in control and treatment groups, respectively. The tumor-muscle ratio was $2.71 ± 0.3\% \text{ ID/g}$ and $3.45 ± 0.4\% \text{ ID/g}$ in control and treatment groups, respectively. The highest normal organ uptake of radioactivity was observed in the kidneys that exhibited the main excretory route of $^{99m}$Tc-glucarate is renal system, also low radioactivities were observed in liver and intestines.

**Macroscopic observation of tumors**

In macroscopic study, in all nude mice, tumoral mass developed for 24 days after ovarian cancer (SKOV-3) implantation. When paclitaxel administration was started, tumoral tissue volume in the treatment group showed a decrease of 2.5 fold at end of experiment (Figure 1).
In the treated group, tumoral masses seemed soft tissues that were easily separated from the surrounding tissue. While in the control group, tumoral specimens had a firm consistency and infiltrated into the muscle adjacent to the site of ovarian cancer cell implanted. Tumoral tissue completely attached to the muscle and separating the tumoral mass from the surrounding tissue was difficult. It was clear that paclitaxel was able to inhibit the tumor metastasis of ovarian cancer to surrounding tissue. So, treated group had less severity of metastasized ovarian cancer as compared to the control group.

**Histopathological findings**

Cancer tissue grew actively in the control group. In microscopic study, multinucleate and high cellularity of ovarian cancer was observed in the control group. Administration of paclitaxel induced the necrotic and fibrotic areas with inhibition of angiogenesis in cancer tissue. Paclitaxel could suppress ovarian tumor growth and inhibit the neovascularization and cell proliferation in tumoral mass. The histopathological findings showed about 20-30% necrosis in tumor samples in paclitaxel treated mice (Figure 2).

**Tumor imaging**

The tumor imaging of female nude mice bearing tumor was evaluated with SPECT at 30 min post-injection of $^{99m}$Tc-glucarate. The uptake of $^{99m}$Tc-glucarate was observed in tumors of control and paclitaxel treated mice (Figure 3).

Tumor can be observed in SPECT scan in control and treated mice; however, tumor visualization in treatment group was more than control mice. The radioactivity uptakes were measured as tumor to muscle ratios in control and paclitaxel treated mice. These ratios were 3.66 and 8.14 for control and anticancer treated mice, respectively. Imaging finding showed higher tumor to muscle ratio (2 fold) than biodistribution data (1.3 fold) in control and paclitaxel treated mice.

**Discussion**

The therapeutic strategy in induction of necrotic pathways converges to achieve a more effective treatment of cancer. Evaluation of necrosis seems to be important for monitoring cancer treatment efficacy in patients. Non-invasive molecular imaging techniques, such as $^{18}$F-FDG-PET have become an essential imaging tool for the assessment of ovarian cancer treatment (24, 25). $^{18}$F-FDG-PET was applied for determination of treatment response in a pre-clinical mouse model of human ovarian cancer xenografts in mice (A2780) treated with carboplatin and paclitaxel. $^{18}$F-FDG uptake was lower (about 1.3 fold) in the anti-cancers treatment group as compared to the control group (26). However, the use of PET is limited due to its high price and unavailability in some areas (12). We showed that $^{99m}$Tc-glucarate as a SPECT imaging agent could be used for in vivo imaging and evaluation of necrotic cells in ovarian tumor. $^{99m}$Tc-glucarate has been used as tumor imaging agent in malignancies of the chest, head and neck, and breast (16-18, 27-30) and lately evaluation of necrotic area in NSCLC tumor (31). $^{99m}$Tc-glucarate binds to exposed histones in necrotic cells (14, 30, 32). It has been shown that tumors with higher amount of necrosis have higher $^{99m}$Tc-glucarate uptake than viable cells (17, 18, 28-30). Paclitaxel treatment markedly decreased $^{18}$F-FDG uptake in human ovarian cancer xenografts in mice (A2780). $^{18}$F-FDG uptake is associated with glucose uptake that is dependent to cell survival and proliferation (25, 26). In our study, $^{99m}$Tc-glucarate uptake was increased in tumor of paclitaxel treated mice with highly degree of necrosis. Since necrotic cells are unable to uptake glucose, $^{99m}$Tc-glucarate is not mediated by glucose uptake in necrotic cells and other mechanisms are involved in the $^{99m}$Tc-glucarate uptake in necrotic cells. Increased uptake of $^{99m}$Tc-glucarate in necrotic cells could be due to the loss of membrane integrity caused by necrosis, which leads to enhance the penetration into the intracellular space.

---

**Table 1. Biodistribution of $^{99m}$Tc-glucarate in female nude mice bearing human ovarian SKOV-3 tumors at 0.5 hr post-injection**

| Tissue         | Control | Treatment (paclitaxel) |
|----------------|---------|-----------------------|
|                | %ID/g   | Tumor/organ*          | %ID/g   | Tumor/organ*          |
| Blood          | 4.47 ± 1.00 | 0.70 | 5390 ± 2.86 | 0.93 |
| Heart          | 1.36 ± 0.33 | 2.38 | 283 ± 0.75 | 1.75 |
| Lung           | 3.69 ± 0.80 | 0.88 | 445 ± 2.01 | 1.24 |
| Salivary glands & Thyroid | 1.99 ± 0.04 | 1.53 | 305 ± 1.39 | 1.77 |
| Liver          | 2.94 ± 0.71 | 1.12 | 443 ± 0.46 | 1.08 |
| Spleen         | 1.03 ± 0.27 | 3.06 | 194 ± 0.18 | 2.45 |
| Kidney         | 49.2 ± 7.77 | 0.06 | 5985 ± 14.06 | 0.08 |
| Stomach        | 1.39 ± 0.25 | 2.27 | 232 ± 0.66 | 2.21 |
| Muscle         | 1.14 ± 0.23 | 2.71 | 138 ± 0.17 | 3.42* |
| Bone           | 2.09 ± 1.25 | 1.36 | 229 ± 0.79 | 2.24 |
| Intestine      | 3.29 ± 0.26 | 0.93 | 466 ± 0.75 | 1.01 |
| Tumor          | 3.05 ± 0.47 | 4.71 ± 0.96*         |        |       |

Each value is the mean ± SD for four mice. *Significant difference between control and paclitaxel therapy, P<0.05. #Tumor/organ means the ratios of tumor per each tissue as tumor/blood, tumor/heart, tumor/lung, etc.
while no membrane damage occurs in viable cells and \( ^{99m} \text{Tc-glucarate} \) has no direct contact with histones. For this reason, the uptake of \( ^{99m} \text{Tc-glucarate} \) varies between necrotic and viable cells (30). Although the exact mechanism of \( ^{99m} \text{Tc-glucarate} \) localization is not understood, it is likely that negatively charged \( ^{99m} \text{Tc-glucarate} \) is attracted to histones and other positively charged proteins. \( ^{99m} \text{Tc-glucarate} \) based on the specific chemical properties of diffusion can be actively or passively transported into cells (14, 15, 27, 30).

In our study, \( ^{99m} \text{Tc-glucarate} \) represents appropriate characteristics with low accumulation in non-tumor soft tissue except in its excretion organs. The tumor uptake of \( ^{99m} \text{Tc-glucarate} \) in treatment group was \( 4.71 \pm 0.96 \text{ ID/g}\%) that was 1.5 fold higher than in control group (3.05\% \pm 0.47\% ID/g \%). In our study, the mean tumor to-muscle ratio for \( ^{99m} \text{Tc-glucarate} \) was \( 3.42\pm0.4 \) and \( 2.71\pm0.3 \) in treatment and control groups, respectively. In other reported study, in U937 leukemia bearing mice, the uptake of \( ^{99m} \text{Tc-glucarate} \) in necrotic tumor was \( 1.71\pm0.2 \text{ ID/g}\% \) that was higher than non-treated control tumor \( 0.61\pm0.11 \text{ ID/g}\% \), and the tumor-muscle ratio was \( 5.76 \pm 0.35 \) and \( 2.5 \pm 0.4 \) in the necrotic and control groups, respectively (30). The higher tumor to muscle ratio and uptake for necrotic U937 tumors could be due to a larger percent necrosis per volume and the time of sacrificing animal after injection. However, this study did not present any SPECT imaging of tumor in control and treated nude mice (30). In our study, the locations of ovarian tumors in the mice thigh were observed in the SPECT images in both groups that were injected with \( ^{99m} \text{Tc-glucarate} \), but tumor image was clearer in paclitaxel treated animal than untreated animal.

**Conclusion**

Inhibiting the growth and proliferation of cancer has become one of the effective strategies in cancer chemotherapy. We examined the use of \( ^{99m} \text{Tc-glucarate} \) as a radiotracer for assessment of paclitaxel-induced tumor cell necrosis in nude mice. In paclitaxel -treated group, it was observed more necrotic cells than in the control group. The results showed that the uptake of \( ^{99m} \text{Tc-glucarate} \) was higher in necrotic area that was caused by paclitaxel. Morphologic findings including inhibition of neovascularization, necrotic area and cell proliferation were more in paclitaxel-treated group as compared to control group. Histopathological examinations confirmed in vivo imaging and biodistribution with \( ^{99m} \text{Tc-glucarate} \) that was able to distinguish necrotic cells from viable cells.
