(March 31, 2002)

I. INTRODUCTION

Entanglement is a quantum mechanical feature that can be employed for computational and communication purposes. During the last few years a big effort has been done in order to create entanglement in several laboratories. This entanglement can then be used for many fascinating things such as teleportation, quantum cryptography, and quantum computation. In some of these experiments the entanglement is produced by starting out from a product state of two systems (typically qubits) and using some physical process that gives rise to an interaction between them. Thus, one of the relevant problems in this context is to find ways of generating "as much entanglement as possible" for a given experimental set–up, i.e. a non–local interaction.

The first steps to answer this problem have been given in Ref. [7–9]. In particular, given a non–local Hamiltonian Dürr et al have found the optimal way of generating entanglement. It consists of applying some fast local operations during the interaction processes in such a way that the rate at which entanglement increases is always maximal. In some situations, however, one cannot apply fast local operations during the process, but rather a fixed quantum gate is given. In this work we will find the states |φ⟩A and |ψ⟩B for which the entanglement of UAB|φ⟩A|ψ⟩B is maximal, where UAB is an arbitrary unitary operator. Thus, our results give a characterization of two–qubit gates in terms of the entanglement that they can produce. For example, we will determine which are the operators UAB that can create maximally entangled states. While most of our results are concerned with two qubits, we will also show that if we allow them to be initially (locally) entangled with some ancillas, one can obtain more entanglement, at least, for certain measures of entanglement.

In general, an arbitrary unitary operator acting on two qubits can be parameterized in terms of 15 coefficients (plus a global phase). Thus, to study the maximum entanglement which can be produced in terms of all these parameters seems a formidable task. However, we will show that one can always decompose UAB = (UA ⊗ UB)Ud(VA ⊗ VB), where Ud has a special form that only depends on three parameters and the rest are local unitary operators. This implies that we can restrict ourselves to characterize operators in the form Ud. The use of the magic basis introduced in Ref. [10] will also considerably simplify our derivations.

This paper is divided into four sections. In Section II we introduce our notation and recall some measures of entanglement and their properties. In Section III we show that there exists a decomposition of any two–qubit gate, which allows us to simplify the problem. In Section IV we consider the problem of two qubits. We determine how much entanglement can be produced by a general two–qubit gate acting on a product state. We also find which of such states give rise to that amount of entanglement. In Section V we discuss the case where we allow the qubits to be initially entangled with ancillas. We will show that the solution to the problem depends on the measure of entanglement we use to quantify it. We will also give two examples in which this problem can be solved analytically for a particular measure of entanglement.

II. DEFINITIONS AND PROPERTIES OF ENTANGLEMENT MEASURES

The purpose of this Section is two fold. On the one hand, we give the definitions and notations that will be used throughout the whole paper. On the other hand, we review some measures of entanglement (for pure states) and some of their properties.

A. Definitions

We consider two partners, Alice and Bob, who posses two quantum systems, A and B, respectively. These systems will be composed of one or two qubits each. We will express the states of these qubits in terms of the computational basis, { |0⟩, |1⟩}. The Hilbert space of system A (B) will be denoted by HA (HB) respectively.

Throughout this paper we use capital Greek letters for joint states of systems A and B and small letters for states describing either system A or system B. We denote by |Ψ⊥⟩ a state which is orthogonal to |Ψ⟩, whereas |Ψ*⟩ denotes the complex conjugate of |Ψ⟩ in the computational basis. We will denote the Pauli operators by

\[ U_{AB} = (U_A \otimes U_B)U_d(V_A \otimes V_B), \]

where Ud has a special form that only depends on three parameters and the rest are local unitary operators.
some global phases. We will denote the elements of this
system an operator is acting on, we specify it with either
a sub- or superscript, e.g. \( \sigma_A \) or \( \sigma_A^4 \).

For two qubits, the Bell basis is defined as follows:
\[
| \Phi^\pm \rangle = \frac{1}{\sqrt{2}} (|00\rangle \pm |11\rangle), \quad | \Psi^\pm \rangle = \frac{1}{\sqrt{2}} (|01\rangle \pm |10\rangle). \tag{1}
\]

We also make use of the so-called magic basis \([10]\), which
is defined in the same way as the Bell-basis except for
some global phases. We will denote the elements of this
basis by
\[
| \Phi_1 \rangle = | \Phi^+ \rangle, \quad | \Phi_2 \rangle = -i | \Phi^- \rangle, \tag{2a}
| \Phi_3 \rangle = | \Psi^- \rangle, \quad | \Phi_4 \rangle = -i | \Psi^+ \rangle. \tag{2b}
\]

The coefficients of a general state in that basis will be typ-
ically denoted by \( \mu_k \); that is, we write \( | \Psi \rangle = \sum_k \mu_k | \Phi_k \rangle \).
In what follows \( | \Phi \rangle \) denotes a maximally entangled state.

B. Measures of entanglement

We review here some measures of entanglement for
pure states. In the first part of the paper we are going
to use the so-called concurrence \([11]\), \( C \). It is defined as
\[
C(|\Psi\rangle) = |\langle \Psi | \sigma_y \otimes \sigma_y | \Psi^+ \rangle|. \tag{3}
\]
Writing \( | \Psi \rangle \) in the magic basis we get
\[
C(|\Psi\rangle) = |\sum_k \mu_k^2|. \tag{4}
\]

In the second part of the paper we will use other
measures of entanglement, which are better expressed
in terms of the Schmidt coefficients. A pure state \( |\Psi\rangle \),
describing the state of two particles, \( A \) and \( B \), each of
dimension \( m \) always has a Schmidt decomposition in the form:
\[
| \Psi \rangle = \sum_{k=1}^{m} c_k | \phi_k \rangle_A | \psi_k \rangle_B, \tag{5}
\]
where \( \langle \phi_k | \phi_l \rangle = \delta_{kl} \forall k,l = 1, \ldots, m \). The real
and positive coefficients \( c_k \), which are the square roots of
the eigenvalues of the reduced density operator, \( \rho_A = \text{tr}_B(|\Psi\rangle \langle \Psi|) \) (or \( \rho_B = \text{tr}_A(|\Psi\rangle \langle \Psi|) \)) are called Schmidt
coefficients. We will choose them in increasing order, i.e.
\( c_1 \leq c_2 \ldots \leq c_m \).

The Entropy of entanglement is defined as follows:
\[
E_E(|\Psi\rangle) \equiv S(\rho_A) = -\text{tr}[\rho_A \log_2(\rho_A)] = -\sum_{k=1}^{m} c_k^2 \log_2(c_k^2). \tag{6}
\]
This measure has a well defined meaning: given \( n \) copies
of a state \( |\Psi\rangle \) then one can produce, using only lo-
cal operations and classical communication, \( nE_E(|\Psi\rangle) \)
maximally entangled states and vice versa (in the limit
\( n \to \infty \)).

Another useful measure is the Schmidt number \([2]\), which
we will denote by \( E_S \). It is the number of Schmidt
coefficients which are different than zero minus one.

There are other set of measures, the so-called Entan-
glement Monotones, which arise in the context of allowed
modification of entangled states under local operations
\([3]\). They are defined as
\[
E_n(|\Psi\rangle) = \sum_{k=1}^{n} c_k^2, \tag{7}
\]
for \( n = 1, \ldots, m - 1 \).

We will also use the so-called 2-Entropy (or 2-Rényi
entropy) of the reduced density operator \([4]\). It is defined as
\[
E_R(|\Psi\rangle) \equiv S_R(\rho_A) = 1 - \text{tr}(\rho_A^2) = 1 - \sum_{k=1}^{m} c_k^2, \tag{8}
\]
where again \( \rho_A \) denotes the reduced density operator of
\( |\Psi\rangle \langle \Psi| \) and \( c_k \) the Schmidt coefficients of
\( |\Psi\rangle \). In the following we will call this measure the Rényi entangle-
ment.

C. Properties

A state describing two qubits contains two Schmidt co-
efficients at most, \( c_1, c_2 \), where \( c_2 = \sqrt{1 - c_1^2} \). Thus, its
entanglement is completely determined by one param-
eter, \( c_1 \). All the measures of entanglement are monotonic
functions of each other and, therefore, equivalent. In
higher dimensions (\( m \)-level systems) though, this is no
longer true. Let us denote now by \( |\Psi\rangle \) and \( |\Psi'\rangle \) two
states describing two \( m \)-level systems. Then it might
happen that for some measure \( |\Psi\rangle \) is more entangled
than \( |\Psi'\rangle \), whereas for some other measure it is the other
way around.

Let us briefly recall some of the properties which have
to be satisfied by any measure of entanglement, \( E \) \([15]\):

(a) Monotonicity under local operations: Suppose that
Alice makes a measurement on her qubit and she
obtains with probability \( p_k \) the state \( \sigma_k \). Then the
entanglement cannot increase on average, i.e:
\[
E(\rho) \geq \sum_k p_k E(\sigma_k). \tag{9}
\]

(b) Convexity: The entanglement decreases if we discard
some information, i.e.
\[
E \left[ \sum_k p_k \rho_k \right] \leq \sum_k p_k E(\rho_k) \tag{10}
\]
Now we briefly summarize some useful properties of the particular measures of entanglement mentioned in the previous subsection. Let us start with the properties of the concurrence, $C$, assuming that we have two qubits:

(i) $C(|\Psi\rangle) = 1$ iff $\mu_k^2 = e^{i\theta}|\mu_k|^2$ $(k = 1,\ldots,4)$. This means that a state, written in the magic basis is maximally entangled iff its coefficients are real, except for a global phase.

(ii) $C(|\Psi\rangle) = 0$ iff $|\Psi\rangle$ is a product state iff $\sum_k \mu_k^2 = 0$.

These two properties imply that if $|\Phi\rangle$ and $|\Phi\rangle$ are real in the magic basis (and therefore they are maximally entangled) then the state $|\Phi\rangle \pm i|\Phi\rangle$ is a product state.

Let us also review some properties of the Entropy of Entanglement, $E_E$, the Schmidt number, $E_S$, the entanglement monotones $E_n$, and the Rényi entanglement, $E_R$, for arbitrary states of two m-level systems:

(1) A maximally entangled state, $|\Psi\rangle$ of two $m$-level systems has $m$ Schmidt coefficients, which are all $1/\sqrt{m}$. Thus $E_E(|\Psi\rangle) = \log_2(m)$, $E_S(|\Psi\rangle) = m - 1$, $E_n(|\Psi\rangle) = nE_1 = n/m$, $(n = 1,\ldots,m - 1)$ and $E_R(|\Psi\rangle) = 1 - 1/m$.

(2) A product state can be written as $|\Psi\rangle = |\phi\rangle_A |\psi\rangle_B$, thus it has only one Schmidt coefficient, which is equal to 1. And so $E_E(|\Psi\rangle) = E_S(|\Psi\rangle) = E_n(|\Psi\rangle) = E_R(|\Psi\rangle) = 0$ $(n = 1,\ldots,m - 1)$.

III. UNITARY OPERATIONS

In the next sections we will calculate the maximum attainable entanglement produced by two-qubit gates. In this section we consider an arbitrary unitary operator $U_{AB}$ acting on two qubits and derive some properties which will simplify the problem.

In Appendix A we show that for any unitary operator $U_{AB}$ there exist local unitary operators, $U_A, U_B, V_A, V_B$, and a unitary operator $U_d$ such that

$$U_{AB} = U_A \otimes U_B U_d V_A \otimes V_B,$$

where

$$U_d = e^{-i\sigma^T \rho \sigma \mu}$$

and $d$ is a diagonal matrix. Here, $\sigma^T$ denotes the transpose of $\sigma$ expressed in the computational basis. We will denote the diagonal elements of $d$ by $\alpha_x, \alpha_y, \alpha_z$. Note that any measure of entanglement is not changed by local unitary operators. Thus the entanglement created by $U_{AB}$ is the same as the one created by $U_d V_A \otimes V_B$. And so the maximal amount of entanglement which can be produced by applying a general unitary, $U_{AB}$ is the same as the one created by $U_d$. This means that we have to deal with unitaries which are determined by only 3 parameters, $(\alpha_x, \alpha_y, \alpha_z)$, instead of 15 parameters, which are used in order to describe a general unitary operator acting on two qubits.

Furthermore, in Appendix B we show that when studying the maximum entanglement created by a two-qubit gate we can restrict ourselves to the case where

$$\pi/4 \geq \alpha_x \geq \alpha_y \geq \alpha_z \geq 0.$$  

(13)

This is due to the fact that the maximal amount of entanglement created by $U_d$ is symmetric around $\pi/4$ and $\pi/2$-periodic in $\alpha_x, \alpha_y$ and $\alpha_z$.

It can be easily shown that the operator $U_d$ is diagonal in the magic basis, and therefore we can write

$$U_d = \sum_{k = 1}^4 e^{-i\lambda_k} |\Phi_k\rangle \langle \Phi_k|.$$  

(14)

The phases $\lambda_k$ are

$$\lambda_1 = \alpha_x - \alpha_y + \alpha_z,$$

$$\lambda_2 = -\alpha_x + \alpha_y + \alpha_z,$$

$$\lambda_3 = -\alpha_x - \alpha_y - \alpha_z,$$

$$\lambda_4 = \alpha_x + \alpha_y - \alpha_z.$$  

(15)

IV. TWO QUBITS

In this section we consider the following scenario. Alice and Bob have one qubit each. They want to entangle them by applying a given unitary operation $U_{AB}$. Their main goal is to find the best separable (pure [16]) input state that gives as much entanglement as possible. According to our previous discussions, we just have to find which states $|\phi\rangle_A |\psi\rangle_B$ maximize the concurrence of the output state $U_d |\phi\rangle_A |\psi\rangle_B$, where $U_d$ is given in (12) with restrictions (13). We will call these states best input states.

Writing the input and output state in the magic basis with the coefficients $w_k, \mu_k$ respectively, we apply the unitary operator $U_d$ and obtain

$$\sum_k \mu_k |\Phi_k\rangle = U_d |\phi\rangle_A |\psi\rangle_B = \sum_k w_k e^{-i\lambda_k} |\Phi_k\rangle.$$  

(16)

We want to maximize the concurrence of the output state, $C = |\sum_k \mu_k^2|$, where we have to make sure that the following conditions are satisfied:

(c1) $\sum_k |\mu_k|^2 = 1$, which is that the output state is normalized. Note that, since $U_d$ is unitary this implies that the input state is normalized.

(c2) $\sum_k \mu_k^2 e^{2i\lambda_k} = 0$. This condition is due to the fact that the input state is a product state, which can be seen as follows. From Eq. (16) we see that $w_k = \mu_k e^{i\lambda_k}$, and according to Section IIC (ii) this last one is a product state iff the sum of the coefficients in the magic basis squared vanishes, which implies the above equation.
We can determine the maximum of the concurrence of the output state under the conditions (c1), (c2) by maximizing $C^2$ and imposing the above conditions in terms of Lagrange multipliers, i.e. we maximize

$$f(\mu_1 \ldots \mu_4) = \sum_{k,l} \mu_k^2 (\mu_l^*)^2 - 2\eta_1 (\sum_k |\mu_k|^2 - 1)$$

$$-\eta_2 \sum_k \mu_k^2 e^{2i\lambda_k} - \eta_2^* \sum_k (\mu_k^*)^2 e^{-2i\lambda_k},$$

where $\eta_1$ is real. We find it convenient to denote $\sum_{i} (\mu_i^*)^2 = C e^{i\gamma}$, $\eta_2 = |\eta_2| e^{i\sigma}$, and $\mu_k = |\mu_k| e^{i\xi_k}$. We obtain

$$\mu_k \sum_{i} (\mu_i^*)^2 = \eta_1 \mu_k^* + \eta_2 \mu_k e^{2i\lambda_k} \quad \forall k.$$  \hspace{1cm} (18)

Multiplying Eq (18) by $\mu_k$, summing over $k$ and using (c1) and (c2) we find that $\eta_1 = C^2$. And so we have, assuming that $C \neq 0$,

$$\mu_k (C e^{i\gamma} - \eta_2 e^{2i\lambda_k})/C^2 = \mu_k^*.$$  \hspace{1cm} (19)

One of the solutions to this equation is $\mu_k = 0$. To find the others we write Eq. (14) as

$$\left| 1 - \frac{|\eta_2|}{C} e^{i(2\lambda_k - \gamma + \xi)} \right| = C.$$  \hspace{1cm} (20)

Let us distinguish now two cases, namely when $\eta_2$ is zero or not.

- **$\eta_2 = 0$:** From Eq. (20) it follows that $C = 1$. Using then Eq. (19) it is easy to see that $e^{2i\xi_k} = e^{-i\gamma} \forall k$. Thus all the coefficients have the same phase (except for the sign) and therefore the output state is, according to the discussions of subsection II C, a maximally entangled state. In order to obtain this state by applying $U_d$ to a product state the conditions, (c1) and (c2) still have to be imposed. In Appendix C we show that those conditions can be fulfilled if $\alpha_x + \alpha_y \geq \pi/4$ and at the same time $\alpha_x + \alpha_y \leq \pi/4$. There, we also determine the best input state.

- **$\eta_2 \neq 0$:** In this case Eq. (20) can have at most two solutions for a fixed value of $|\eta_2|/C$. Thus, in order to fulfill (18) $\forall k$ at least two of the coefficients have to vanish. \hspace{1cm} (15). Let us call the other two $\mu_k$ and $\mu_l$. Then, in order to fulfill conditions (c1) and (c2) we have to satisfy $|\mu_k|^2 + |\mu_l|^2 e^{2i(\lambda_l - \lambda_l + \xi_k)} = 0$ and the normalization condition. Thus $|\mu_k| = |\mu_l| = 1/\sqrt{2}$ and the difference between the two phases $\xi_k$ and $\xi_l$ is $\lambda_l - \lambda_k - \pi/2$. With all that it is now simple to determine that the largest reachable concurrence is

$$C = \max_{k,l} |\sin(\lambda_k - \lambda_l)|.$$  \hspace{1cm} (21)

Except for global phases the corresponding output state is $1/\sqrt{2}(|\Phi_k) + i|\Phi_l) e^{i\lambda_k - \lambda_l})$ and the separable input state, which leads to this maximum is

$$\frac{1}{\sqrt{2}}(|\Phi_k) + i|\Phi_l>).$$  \hspace{1cm} (22)

Note that the input state $1/\sqrt{2}(|\Phi_k) - i|\Phi_l))$ (the corresponding output state would then be $1/\sqrt{2}(|\Phi_k) - i|\Phi_l) e^{i\lambda_k - \lambda_l})$) leads to the same amount of entanglement.

Note that in case $\alpha_x \leq \pi/8$, we obtain that $C = \sin(\alpha_x + \alpha_y)$, which is directly related to the entanglement capability of the Hamiltonian of the form $\sigma_A^x \sigma_B^x$. For higher values of $\alpha_x$ the result may not be directly related to that quantity.

In summary, in this subsection we have shown that if we apply $U_d$ to a separable input state and calculate the maximum of the concurrence of the output state, then we find: If $\alpha_x + \alpha_y \geq \pi/4$ and $\alpha_y + \alpha_x \leq \pi/4$ then this maximum is equal to 1. Otherwise it is given by (21). In addition we determined the best input state in each of those two cases. Note that, since we were dealing with two-qubit states we could have taken, according to the discussions in section II C, any other measure of entanglement to obtain the same result.

**V. USING ANCILLAS**

We analyze now whether and how it would be possible to increase the amount of entanglement of the output state with the help of auxiliary systems. So, we consider the situation where Alice and Bob have two qubits each \hspace{1cm} (15). Let us denote the auxiliary qubits by $A'$ and $B'$. We allow input states in which Alice and Bob’s qubits are locally entangled, i.e. of the form $|\phi)_{AA'} |\psi)_{BB'}$. Then they apply a non-local unitary transformation, $U_{AB}$ to the qubits $A$ and $B$. The question is, then, for which $|\phi)_{AA'}$ and $|\psi)_{BB'}$ they are able to reach

$$\max(|\phi)_{AA'} |\psi)_{BB'} E(U_{AB} \otimes I_{A'B'} |\phi)_{AA'} |\psi)_{BB'}),$$

where $E$ denotes some measure of entanglement. In what follows we write again simply $|\phi) (|\psi)$ instead of $|\phi)_{AA'} (|\psi)_{BB'}$. On the other hand, according to Section III, we can restrict ourselves to operators $U_d$ of the form (13). For convenience we will call the input state where $|\phi)$ and $|\psi)$ are both maximally entangled, local maximally entangled and the one where both are product states, local product state.

The main difference with the previous section is that now the best input states depend on the measure of entanglement. To illustrate this fact we show in the first subsection that for some measures of entanglement the best input states are the ones where $|\phi)$ and $|\psi)$ are entangled. On the other hand, there are measures of entanglement for which a local product state is the best input state.
In the second subsection we show that for some special class of $U_d$ (where $d$ has only one non vanishing element) the solution to our problem is independent of the measure of entanglement. In particular, we show how much entanglement can be created in this case and what is the best input state. Furthermore, for the class of $U_d$ where all the diagonal elements of $d$ are the same we will determine the maximum Rényi entanglement as well as the best input state according to this measure of entanglement.

A. Dependence on the measure of entanglement

Let us compare the answer to our problem for some of the measures of entanglement which we recalled in Section II. According to some numerical examples we have that:

- Schmidt number: Local maximum entangled states are always better than local product states. This can be easily understood since in the first case the maximum value which $E_S$ can take is 4, whereas in the latter one it can be at most 2. Thus using this measure of entanglement the ancillas will in general increase the entanglement of the output state.

- Rényi entanglement: We have checked that for this measure the best input states are always either local product states or local maximally entangled states. In particular, in the next subsection we will provide analytical results for some particular cases.

- Entanglement monotones: We have verified that there are unitary operators $U_d$ for which local product states are the best input states, whereas for some other values the local maximally entangled states lead to the most entangled output state. But there also exist some $U_d$ for which neither the product state nor the maximally entangled state are the best input states.

From these examples it becomes clear that it does not make much sense to ask for the best input state, if one does not specify according to which measure of entanglement.

B. Examples

Before we start with the examples let us make some general statement about the input state. It can always be written in the Schmidt decomposition as

\[
|\phi\rangle_{AA'} = c_A |0\rangle_A |0\rangle_A' + s_A |\phi^+_A\rangle_A |1\rangle_A',
\]
\[
|\psi\rangle_{BB'} = s_B |\psi_0\rangle_B |0\rangle_B + c_B |\psi^+_B\rangle_B |1\rangle_B',
\]

where $c_A^2 + s_A^2 = c_B^2 + s_B^2 = 1$. This is due to the fact that local unitaries applied to $A'$ and $B'$ do not change the entanglement (and commute with $U_d$). Let us now treat two cases in which it is possible to determine the best input state for some measures of entanglement. The first one should be viewed as a very simple illustration, whereas the second one is much more involved.

1. Example 1

Let us consider the following simple unitary operator,

\[
U_d = e^{-i\alpha S_z} = \cos(\alpha)1 - i \sin(\alpha)\sigma_z \otimes \sigma_z.
\]

In this case it is fairly simple to determine the output state. It has at most 2 Schmidt coefficients and therefore the state can be viewed as a state describing two qubits. This implies, as discussed in II C, that all the measures of entanglement are equivalent when calculating the optimal states. We take $E_E$.

Let us define $\rho_1$ as the density operator whose off-diagonal elements are zero, whereas the diagonal elements are the same as the one of the state $\rho$. Using the fact that the von Neumann entropy is convex we have that $S(\rho_1) \geq S(\rho)$. Apart from that, since the problem is symmetric under exchanging system $(AA')$ with $(BB')$, it is easy to verify that the states with $\sigma_x |\phi\rangle \propto |\phi^\perp\rangle$ and $\sigma_x |\psi\rangle \propto |\psi^\perp\rangle$ lead to the most entangled output state. Now, since the states $|\phi\rangle = |1\rangle, |\psi\rangle = |1\rangle$, as well as the states $|\phi\rangle = |\Phi^+\rangle, |\psi\rangle = |\Phi^+\rangle$ fulfill this condition, both, a local product state and a local maximally entangled state are the best input states. The maximal entropy of entanglement which can be obtained is then

\[
\text{max} E_E = -\cos(\alpha)^2 \log_2[\cos(\alpha)^2] - \sin(\alpha)^2 \log_2[\sin(\alpha)^2].
\]

2. Example 2

Here we determine the best input state, according to the Rényi entanglement, corresponding to a unitary of the form

\[
U_d = e^{-i\alpha(S_x + S_y + S_z)} = (\cos(\alpha)^3 - i \sin(\alpha)^3)1 - i \sin(\alpha) \cos(\alpha) e^{i\alpha} (S_x + S_y + S_z),
\]

where $S_\beta = \sigma_\beta \otimes \sigma_\beta$ ($\beta = x, y, z$). Here we have used $[S_x, S_y] = [S_x, S_z] = [S_y, S_z] = 0$. In Appendix D we show that, according to any measure of entanglement the best input state can always be written as

\[
|\phi\rangle_{AA'} = c_a |0\rangle_A |0\rangle_A' + s_a |\phi^+_A\rangle_A |1\rangle_A',
\]
\[
|\psi\rangle_{BB'} = s_b |\psi_0\rangle_B |0\rangle_B + c_b |\psi^+_B\rangle_B |1\rangle_B',
\]

where $s_a^2 + c_a^2 = s_b^2 + c_b^2 = 1$.

Let us start by proving that the best input state is either a local product state or a local maximally entangled state. Calculating the reduced density operator one
finds that $\rho_A = \rho_1 \oplus \rho_2$ (tr$(\rho_1\rho_2) = 0$), where $\rho_1,\rho_2$ are $2 \times 2$ matrices which depend on $s_a, s_b$ and $\alpha$. It is straightforward to calculate $E_R(U_d|\phi\rangle\langle\psi|) = S_R(\rho_A) = S_R(\rho_1) + S_R(\rho_2)$ and determine its maxima. One finds that the either the local product states ($s_a^2, s_b^2 = 0, 1$) or the local maximally entangled states $s_a^2 = s_b^2 = 1/2$ always lead to a maximum of the Rényi entanglement. In the case of a local product state, it is easy to check that the best one is $|01\rangle$ (or equivalently $|10\rangle$) Let us denote by $E^m.e$ ($E^p.v$) the Rényi entanglement for a local maximally entangled input state (product state $|01\rangle$) respectively. We obtain

\begin{align*}
E^m.e_R(\alpha) &= \frac{3}{16}[3 - 2\cos(4\alpha) - \cos(4\alpha)^2] \quad (28a) \\
E^p.v_R(\alpha) &= \frac{1}{2}[1 - \cos(4\alpha)^2]. \quad (28b)
\end{align*}

Comparing those two expressions we find that $\alpha_0 = \arccos(1/5)/4 \approx 0.109\pi$. So we have that $\forall \alpha < \alpha_0$ the local product state is the best input state and otherwise the local maximally entangled state leads to the output state with the largest Rényi entanglement. In Fig. 1 we illustrate this result.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1}
\caption{Rényi entanglement for the local maximally entangled input state $|1\rangle$ and for the product state $|01\rangle$ (2)}
\end{figure}

VI. CONCLUSIONS

We have shown which separable pure two–qubit states have to be used in order to create as much entanglement as possible by applying a general two–qubit gate. We have shown which unitary operators are able to create a maximally entangled state. For all the other unitary operators we have given the maximal amount of entanglement which can be created by them (Eq. (21)). Furthermore we have shown that by using ancillas one has to specify which is the measure of entanglement to be maximized. We have given two examples of unitary operations for which it is possible to determine the maximal amount of some particular measure of entanglement.

VII. ACKNOWLEDGMENTS

APPENDIX A: DECOMPOSITION OF UNITARY OPERATORS

In this appendix we show that for any unitary operator $U_{AB}$ acting on two qubits there exist local unitary operators $U_A, U_B, V_A, V_B$ and a non–local unitary $U_d = e^{-i\delta k_{AB}}$ (d diagonal) such that

$$U_{AB} = U_A \otimes U_B U_d V_A \otimes V_B. \quad (A1)$$

Our prove will be constructive. Let us call a basis consisting of maximally entangled orthonormal states a maximally entangled basis. In what follows the use of the subscript $k$ implies that the definition or statement is true for $k = 1, \ldots, 4$, if not stated differently.

**Lemma 1:** For any maximally entangled basis $\{ |\Psi_k\rangle\}$, there exist phases $\zeta_k$ and local unitaries $U_A, U_B$ such that

$$U_A \otimes U_B e^{i\zeta_k} |\Psi_k\rangle = |\Phi_k\rangle. \quad (A2)$$

**Proof:** According to the discussion in Subsection IIC (i) we can always write $|\Psi_k\rangle = e^{i\delta_k} |\Psi_k\rangle$, where $|\Psi_k\rangle$ is real in the magic basis. Let us consider two different states, $|\Psi_k\rangle$ and $|\Psi_l\rangle$, then $1/\sqrt{2}( |\Psi_k\rangle - i |\Psi_l\rangle ) = |e,f\rangle$ and $1/\sqrt{2}( |\Psi_k\rangle + i |\Psi_l\rangle ) = |e,\bar{f}\rangle$, where $|e,\bar{f}\rangle \in H_A$ and $|f,\bar{e}\rangle \in H_B$. Note that $|e,f\rangle$ must be orthogonal to $|\bar{e},\bar{f}\rangle$. This immediately implies that these vectors must give the Schmidt decomposition of both $|\Psi_{k,l}\rangle$. Thus we can write

$$|\Psi_1\rangle = \frac{1}{\sqrt{2}} (|e,f\rangle + |e^\perp, f^\perp\rangle) \quad (A3)$$

$$|\Psi_2\rangle = \frac{-i}{\sqrt{2}} (|e,f\rangle - |e^\perp, f^\perp\rangle). \quad (A4)$$

Using the same arguments for $|\Psi_{3,4}\rangle$ it is easy to determine that they can be written as

$$|\Psi_3\rangle = \frac{-i}{\sqrt{2}} (e^{i\delta} |e,f\rangle + e^{-i\delta} |e^\perp,f\rangle) \quad (A5a)$$

$$|\Psi_4\rangle = \pm \frac{1}{\sqrt{2}} (e^{i\delta} |e,\bar{f}\rangle - e^{-i\delta} |\bar{e},\bar{f}\rangle) \quad (A5b)$$

for some $\delta$. In this case, choosing

$$U_A = |0\rangle\langle e| + |1\rangle\langle e^\perp| e^{i\delta}, \quad (A6a)$$

$$U_B = |0\rangle\langle f| + |1\rangle\langle f^\perp| e^{-i\delta} \quad (A6b)$$

These operators act on two qubits and $U_d$ is a diagonal unitary which is used to obtain the desired basis.
and the phases $\xi_k$ appropriately, we have (A4). □.

Note that this first lemma implies that one can go from one maximally entangled basis to any other using only local unitaries, if one chooses the global phases appropriately.

**Lemma 2:** Given a general unitary operator, then there always exist phases $\xi_k$ and two maximally entangled basis $\{|\Psi_k\rangle\}$ and $\{|\tilde{\Psi}_k\rangle\}$ such that

$$U|\Psi_k\rangle = e^{i\xi_k}|\tilde{\Psi}_k\rangle.$$  \hspace{1cm} (A7)

**Proof:** We give a constructive proof. Let us denote by $\{|\Psi_k\rangle\}$ the eigenstates of $U^TU$, where $U^T$ denotes the transpose of $U$ in the magic basis and $e^{2i\xi_k}$ are the corresponding eigenvalues. Note that the eigenvectors of the symmetric operator $U^TU$ are orthonormal and real, except for global phases. Thus, since we are working in the magic basis, they build a maximally entangled basis. Now we define $|\tilde{\Psi}_k\rangle$ as

$$|\tilde{\Psi}_k\rangle \equiv e^{-i\xi_k}U|\Psi_k\rangle.$$  \hspace{1cm} (A8)

Since the set $\{|\tilde{\Psi}_k\rangle\}$ also form an orthonormal basis, it remains to prove that its elements are real. In order to show that let us consider the eigenvalue equation, $(U^TU - e^{2i\xi_k}1)|\tilde{\Psi}_k\rangle = 0$. Multiplying it by $U^*e^{-i\xi_k}$ we get that $(e^{-i\xi_k}U - e^{i\xi_k}U^*)|\tilde{\Psi}_k\rangle = 0$, which is true iff $e^{-i\xi_k}U|\tilde{\Psi}_k\rangle$ is real □.

With all that we are now in the position to show that any unitary operator can be decomposed into local operators and $U_d$ as in Eq.(A1). So let us now give the procedure to determine the unitary operators that appear there.

1) Calculate the eigensystem of the unitary, symmetric operator $U^TU$. Let us denote the eigenvalues by $e^{2i\xi_k}$ and the eigenstates by $|\Psi_k\rangle$. As proven in Lemma 2 the set of those states is a maximally entangled basis.

2) Choose $V_A, V_B$ and the phases $\xi_k$, as explained in Lemma 1, such that

$$V_A \otimes V_B e^{i\xi_k} |\Psi_k\rangle = |\Phi_k\rangle.$$  \hspace{1cm} (A9)

3) Calculate

$$|\tilde{\Psi}_k\rangle = e^{-i\xi_k}U|\Psi_k\rangle.$$  \hspace{1cm} (A10)

Note that according to Lemma 2 the set of those states is also a maximally entangled basis.

4) Choose the eigenvalues of $U_d$, $e^{i\lambda_k}$ (note that this is equivalent to choose the diagonal elements of $d$) and the unitary operators $U_A, U_B$ such that

$$U_A^\dagger \otimes U_B^\dagger e^{i(\lambda_k + \xi_k + \epsilon_k)}|\tilde{\Psi}_k\rangle = |\Phi_k\rangle,$$  \hspace{1cm} (A11)

which, according to Lemma 1, is always possible. It is simple to check that with these definitions we obtain the decomposition $\{A1\}$.  

---

**APPENDIX B: PERIODICITY AND SYMMETRY OF THE MAXIMAL AMOUNT OF ENTANGLEMENT**

Let us start out by proving the periodicity of the entanglement created by $U_d$. We define $d,d'$ as a matrix whose diagonal elements are $\alpha_x, \alpha_y, \alpha_z \ (\alpha_x + \pi, \alpha_y, \alpha_z)$ respectively. It is simple to verify that $U_d = -iS_zU_{d'}$.

Since $S_z$ is a tensor product of two local unitary operators the entanglement created by $U_d$ is the same as the one created by $U_{d'}$. The same argument holds for $\alpha_y$ and $\alpha_z$ and therefore the amount of entanglement created by $U_d$ is $\pi/2$ periodic in $\alpha_x, \alpha_y, \alpha_z$.

To prove the symmetry around $\pi/4$ in $\alpha_x, \alpha_y, \alpha_z$ of the maximal amount of entanglement we use the following definition: $d, (d')$ is a matrix whose diagonal elements are $\pi/4 + \alpha_x, \alpha_y, \alpha_z \ (\pi/4 - \alpha_x, \alpha_y, \alpha_z)$. It is straightforward to show that $U_d = -ia_x^\dagger U_d^\dagger d'^\dagger$, where $U_{d'}$ denotes the complex conjugate of $U_d$ in the standard basis. And so we have that $E(U_d | \Psi\rangle) = E(U_{d'} | \sigma_x^d | \Psi\rangle)$. It is clear that the maximal amount of entanglement created by $U_d$ is the same as the one created by $U_{d'}$. Again the same argumentation holds for the other angles, which proves the statement.

---

**APPENDIX C: TWO-QUBIT GATES WHICH CREATE MAXIMALLY ENTangled STATES**

We are going to prove here that there exists a normalized product state $|\phi\rangle \langle \psi|$ such that $|\Phi\rangle = U_d |\phi\rangle \langle \psi|$ is a maximally entangled state iff $\alpha_x + \alpha_y \geq \pi/4$ and $\alpha_x + \alpha_z \geq \pi/4$.

According to our discussions in Subsection II C and Section IV, this is equivalent to fulfilling the conditions (c1) and (c2), where $\mu_k^2 = |\mu_k|^2 e^{-i\gamma}$. Multiplying condition (c2) by $e^{-i(\gamma + 2\lambda_k)}$, we obtain

$$|\mu_k|^2 + |\mu_1|^2 e^{i\alpha_2} + |\mu_2|^2 e^{i\alpha_3} + |\mu_4|^2 e^{i\alpha_4} = 0,$$  \hspace{1cm} (C1)

where we have defined $\alpha_1 = 4(\alpha_x + \alpha_y), \alpha_2 = 4(\alpha_x + \alpha_z)$ and $\alpha_3 = 4(2\alpha_y + \alpha_z)$. Note that since $\pi/4 \geq \alpha_x \geq \alpha_y \geq \alpha_z \geq 0$, we have that $2\pi \geq \alpha_1 \geq \alpha_2 \geq \alpha_3 \geq 0$.

Let us distinguish the following two cases now:

- $\alpha_1 < \pi$ (or $\alpha_3 > \pi$). In this case all the imaginary parts appearing in Eq. (C1) are positive (negative) and therefore the sum can never vanish.

- $\alpha_1 \geq \pi$ and $\alpha_3 \leq \pi$. Here the imaginary part of $|\mu_4|^2 e^{i\alpha_4}$ is negative, whereas the one of $|\mu_2|^2 e^{i\alpha_3}$ is positive and therefore it is always possible to find a
solution to Eq. (C1). In particular we can choose $\mu_k = 0$. Then writing the real and imaginary part of Eq. (C1) and the normalization condition (c1) we simply have to solve:

$$\sin(\alpha_3)|\mu_2|^2 + \sin(\alpha_1)|\mu_4|^2 = 0 \quad \text{(C2)}$$
$$|\mu_3|^2 + \cos(\alpha_3)|\mu_2|^2 + \cos(\alpha_1)|\mu_4|^2 = 0 \quad \text{(C3)}$$
$$|\mu_2|^2 + |\mu_3|^2 + |\mu_4|^2 = 1. \quad \text{(C4)}$$

Note that since we have found the solution for the $\mu_k$'s, it is easy to determine the input state by using the formula $w_k = \mu_ke^{i\lambda_k}$.

**APPENDIX D: BEST INPUT STATE FOR EXAMPLE 2**

Here we prove that the input state which leads to the most entangled output state can be written as

$$|\phi\rangle = c_a|00\rangle + s_a|11\rangle \quad \text{(D1a)}$$
$$|\psi\rangle = s_b|00\rangle + c_b|11\rangle, \quad \text{(D1b)}$$

where $s_a^2 + c_a^2 = s_b^2 + c_b^2 = 1$. We will use that $|\sigma_A^B \otimes \sigma_B^A|, U_A|\psi\rangle = 0$, where $\sigma_B = \sigma \cdot \vec{n}$. This can be easily verified using the commutation relations of the Pauli operators.

Let us now recall that the input state in system AA' can be written as $|\phi\rangle = c_a|\phi_b\rangle_A|0\rangle_{A'} + s_a|\phi_b^+\rangle_A|1\rangle_{A'}$, where $c_a^2 + s_a^2 = 1$. It is clear that there exists a vector $\vec{n}$ such that $|\sigma_B|\phi\rangle = |\phi\rangle$ and $|\sigma_B|\phi^+\rangle = -|\phi^+\rangle$. Note that $|\phi\rangle$ is invariant under $\sigma_A^B \otimes \sigma_A^A$, i.e.

$$|\sigma_A^B \otimes \sigma_A^A| |\phi\rangle = |\phi\rangle. \quad \text{(D2)}$$

Using the fact that $U_A$ commutes with $\sigma_A^B \otimes \sigma_A^A$ and with local operators acting on the auxiliary systems together with Eq. (D2) we have that, $|\sigma_A^B \otimes \sigma_A^A| V_B U_A|\psi\rangle = \tilde{U}_A|\phi\rangle |\sigma_B^A \otimes V_B|\psi\rangle$, for any unitary operator $V_B$.

Let us now introduce a new auxiliary system which we denote by C. Then, using the convexity (10) of any measure of entanglement, E, we have that

$$E(U_{AB}|\phi\rangle_{AA'}|\psi\rangle_{BB'C}) \geq E(U_{AB}|\phi\rangle_{AA'}|\psi\rangle_{BB'}), \quad \text{(D3)}$$

where

$$|\psi\rangle_{BB'C} = 1/\sqrt{2}(|\psi\rangle_{BB'}|0\rangle_C + |\psi\rangle_{BB'}|1\rangle_C). \quad \text{(D4)}$$

Now choosing $V_{B'} = \sigma_B^A$ and requiring that $|\psi\rangle_{BB'} = |\psi\rangle_{BB'}$, which implies that $|\psi\rangle = s_b|\phi_0\rangle + c_b|\phi_1\rangle$, we get that $E(U_{AB}|\phi\rangle_{AA'}|\psi\rangle_{BB'}) \geq E(U_{AB}|\phi\rangle_{AA'}|\psi\rangle_{BB'})$, $\forall\langle\phi|, |\psi\rangle$, where both, $|\phi\rangle$ and $|\psi\rangle$ are invariant under the operation $\sigma_B^A \otimes \sigma_B^A$. Using the same argumentation as before, we can apply the local operator $\sigma_B^A \otimes \sigma_B^A$, where $\vec{n}$ is defined as $\sigma_B^A|\phi_0\rangle = |0\rangle$ and $\sigma_B^A|\phi_1\rangle = -|1\rangle$. Combining all that we have that

$$E(U_{AB}|\phi\rangle|\psi\rangle) \leq E(U_{AB}|(c_a|00\rangle + s_a|11\rangle)(s_b|00\rangle + c_b|11\rangle)), \quad \text{(D5)}$$

$\forall |\phi\rangle, |\psi\rangle$.

[16] Note that the maximum entanglement reached for pure states is always larger than the one reached by a mixed state. This can be seen as follows: let us write an arbitrary mixed state, $\rho$, in its eigenbasis, i.e $\rho = \sum_k p_k |\psi_k\rangle \langle \psi_k|$. Using the convexity of any measure of entanglement, $E$, (10) we have that $E(\rho) \leq \max\langle\psi_k|E(|\psi_k\rangle)$, thus it suffices to consider only pure states.
[17] Note that if two or more $\lambda$’s are equal, this does not need to be necessary. However, we can discard this case since it has zero measure in the set of unitary operators, and obtain this result by imposing continuity.
[18] Note that since one of Alice’ and Bob’s subsystems (the ones on which they apply the unitary operator) are
qubits, the state describing such a subsystem and an ancilla of arbitrary dimension can always be viewed as a state describing two qubits (it has at most two Schmidt coefficients).

[19] Note that, due to the symmetry of the problem, the entanglement produced by the input state $|01\rangle$ has to be the same as the one produced by $|10\rangle$.
