Complete electroweak two-loop corrections to $Z$ boson production and decay

Ivgen Dubovyk, Ayres Freitas, Janusz Głuza, Tord Riemann, Johann Usovitsch

Abstract

This article presents results for the last unknown two-loop contributions to the $Z$-boson partial widths and $Z$-peak cross-section. These are the so-called bosonic electroweak two-loop corrections, where “bosonic” refers to diagrams without closed fermion loops. Together with the corresponding results for the $Z$-pole asymmetries $A_1, A_0$, which have been presented earlier, this completes the theoretical description of $Z$-boson precision observables at full two-loop precision within the Standard Model. The calculation has been achieved through a combination of different methods: (a) numerical integration of Mellin-Barnes representations with contour rotations and contour shifts to improve convergence; (b) sector decomposition with numerical integration over Feynman parameters; (c) dispersion relations for sub-loop insertions. Numerical results are presented in the form of simple parameterization formulae for the total width, $\Gamma_Z$, partial decay widths $\Gamma_{\ell\ell,\mu\tau}, \Gamma_\ell, \Gamma_\nu, \Gamma_u, \Gamma_c, \Gamma_d, \Gamma_b$, branching ratios $R_1, R_\ell, R_b$, and the hadronic peak cross-section, $\sigma_{\text{had}}^{Z\rightarrow\ell\ell}$. Theoretical intrinsic uncertainties from missing higher orders are also discussed.

1. Introduction

The number of $Z$ bosons collected at LEP in the 1990’s, $1.7 \times 10^7$, together with SLD data made it possible to determine electroweak pseudo-observables (EWPOs) with high precision: the $Z$-boson mass $M_Z$, its decay width $\Gamma_Z$, branching ratios $R$, forward-backward and left-right asymmetries (or equivalently $A_f$ or $\sin^2 \theta_{\text{eff}}$) [1]. At that time, theoretical calculations, which included complete one-loop Standard Model corrections, selected higher order QCD corrections, and partial electroweak two-loop results with intricate QED resummations, were accurate enough to go hand-in-hand with experimental demands [2,3]. However, up to $5 \times 10^{12}$ $Z$-boson decays are planned to be observed at projected future $e^+e^-$ machines (ILC, FCC-ee, CEPC) running at the $Z$-boson resonance [4,7]. These statistics are several orders of magnitude larger than at LEP and would lead to very accurate experimental measurements of EWPOs. Limitations will come from experimental systematics, but they are in many cases estimated to be improved by more than an order of magnitude compared to the LEP experiments [4,7]. This raises a new situation and theoretical calculations must be much more precise than assumed before [4,7]. The improved precision will provide a platform for deep tests of the quantum structure of nature and unprecedented sensitivity to heavy or super-weakly coupled new physics.

As an important step towards that goal, this article reports on the completion of such calculations at the two-loop level in the Glashow-Weinberg-Salam gauge theory, known as the Standard Model (SM) [10-12]. The first non-trivial study of electroweak (EW) loop effects was the calculation of the large quadratic top quark mass contribution to the $Z$ and $W$ propagators at one-loop order [13]. A few years later, the on-shell renormalization scheme as it is used today [14] and the notion of effective weak mixing angles [15] were introduced, and the scheme was used for calculations of the $W^\pm$ and $Z$ boson masses [16]. The complete one-loop corrections to the $Z$ decay parameters were derived in Refs. [17-20], and those to the $W^\pm$ width in Refs. [19,21,22]. Through the years of LEP and SLC studies, the effects of EW corrections became visible in global fits of the SM parameters [13-23]. Global fits to EW precision measurements allowed to predict the mass of the top quark and the Higgs boson prior to their discoveries at Tevatron in 1995 [24,25] and at the LHC in 2012 [26].

At future $e^+e^-$ colliders, EWPOs will again play a crucial role. These include the total and partial widths of the $Z$ boson and the $Z$-boson couplings. The latter can be extracted from measurements of the cross-section and polarization and angular asymmetries of the processes $e^+e^- \rightarrow (Z) \rightarrow f\bar{f}$. Here $f$ stands for any SM lepton or quark, except the top quark, whereas the notation $(Z)$ is supposed to indicate that the amplitude is dominated by the $s$-channel $Z$-boson resonance, but there is contamination from photon and two-boson backgrounds.

Already for the precision achieved at LEP and SLC, the calculation of loop corrections beyond the one-loop order was necessary to keep theory uncertainties under control. Specifically, these included two-loop $O(\alpha\alpha_s)$ [27,31] and fermionic $O(\alpha^2)$ [32,46] corrections to the Fermi constant, which can be used to predict the $W$-boson mass, and to the $Z$-pole parameters. Here $\alpha$ refers to an electroweak loop order, whereas “fermionic”

denotes contributions from diagrams with at least one closed fermion loop. In addition, leading three- and four-loop results, enhanced by powers of the top Yukawa coupling $y_t$, were obtained at order $O(\alpha, \alpha^2)$ [41, 48], $O(\alpha^2 \alpha_{\tau})$, $O(\alpha^2)$ [49, 50], and $O(\alpha \alpha_{\tau}^2)$ [51, 52], where $\alpha_t = y_t^2/(4\pi)$.

For the EW two-loop corrections, the calculation of the fermionic contributions was a natural first step, since these are numerically enhanced by the numbers of flavors and colors and by powers of $y_t$. Moreover, the fermionic two-loop diagrams are relatively simpler than the full set. For example, the latter includes non-planar vertex topologies, which are absent in the former. The remaining bosonic two-loop corrections to the Fermi constant and the leptonic effective weak mixing angle, $\sin^2 \theta^e_{\text{eff}}$, have subsequently been presented in Refs. [54–60], and more recently also for the weak mixing angle in the $b \bar{b}$ channel [61].

While the numerical effects of the bosonic two-loop corrections are relatively small compared to the current experimental precision from LEP and SLC, their inclusion will become mandatory for future $e^+ e^-$ colliders. Thus the computation of the full two-loop corrections for all $Z$-pole EWPOs is an important goal. This article completes this goal by presenting the technical aspects of the two-loop calculation are described in section 3. The numerical impact of the bosonic EW two-loop corrections is demonstrated in section 4. In particular, results for the total and partial widths, and the hadronic $Z$-peak cross-section are given in terms of simple parameterization formulae, which provide an accurate description of the full results within the currently allowed ranges of the input parameters. Finally, the theory uncertainty from missing three- and four-loop contributions is estimated in section 5 before concluding in section 6.

2. Definition of the observables

The amplitude for $e^+ e^- \to f \bar{f}$ near the $Z$ pole, $\sqrt{s} \approx M_Z$, can be written in a theoretically well-defined way as a Laurent expansion around the complex pole $s_0 \equiv M_Z^2 - iM_Z \Gamma_Z$.

$$A[e^+ e^- \to f \bar{f}] = \frac{R}{s - s_0} + S + (s - s_0) S' + \ldots, \quad (1)$$

where $M_Z$ and $\Gamma_Z$ are the on-shell mass and width of the $Z$ boson, respectively. According to eq. (1), the approximate line shape of the cross-section near the $Z$ pole is given by $\sigma \propto \left[ (s-M_Z^2)^2 + M_Z^2 \Gamma_Z^2 \right]^{-1}$. It is important to note that this differs from the line shape used in experimental analyses, which is of the form $\sigma \propto \left( (s-M_Z^2)^2 + \Gamma_Z^2/M_Z^2 \right)^{-1}$. As a result, the parameters in eq. (1) differ from the experimental mass $M_Z$ and width $\Gamma_Z$ from LEP by a fixed factor [62]:

$$M_Z = M_Z/\sqrt{1 + \Gamma_Z^2/M_Z^2},$$

$$\Gamma_Z = \Gamma_Z/\sqrt{1 + \Gamma_Z^2/M_Z^2}. \quad (2)$$

Numerically, this leads to $M_Z \approx M_Z - 34 \text{ MeV}$ and $\Gamma_Z \approx \Gamma_Z - 0.9 \text{ MeV}$.

The total width, $\Gamma_Z$, can be extracted from the condition that the $Z$ propagator has a pole at $s = s_0$, leading to

$$\Gamma_Z = \frac{1}{M_Z} \text{Im} \Sigma_Z(s_0), \quad (3)$$

where $\Sigma_Z(s)$ is the transverse part of the $Z$ self-energy. Using the optical theorem, it can also be written as [43–46]:

$$\Gamma_Z = \sum_f \Gamma_f, \quad (4)$$

$$\Gamma_f = \frac{N_{f}}{12\pi} \left[ \mathcal{R}_f(0) F_f^{(1)} + \mathcal{R}_f(1) F_f^{(2)} \right] s = M_Z^2, \quad (5)$$

Here the sum runs over all fermion types besides the top quark, $f = e, \mu, \tau, \nu_e, \nu_\mu, \nu_\tau, u, d, c, s, b$, and $N_f = 3(1)$ for quarks (leptons). The radiator functions $\mathcal{R}_f(0,1)$ capture the effect of final-state QED and QCD corrections. They are known up to $O(\alpha)$ and $O(\alpha^2)$ for massless external fermions and $O(\alpha^3)$ for the kinematic mass corrections [63–65]. For the results shown in this article, the explicit form given in the appendix of Ref. [46] has been used.

The remaining radiative corrections are IR finite and contained in the form factors $F_f^{(0,1)}$. These include massive EW corrections as well as mixed EW–QCD and EW–QED corrections. The bosonic two-loop contributions, which are of interest for this article, contribute according to [46]:

$$F_{V}^{(2)} = 2 \Re \left[ \left( v_{f(0)} v_{f(2)} + |v_{f(1)}|^2 \right) \right] - v_{f(0)}^2 \Re \Sigma_Z^{(2)} - (\Re \Sigma_Z^{(1)})^2 \right],$$

$$- 2 \Re \left( v_{f(0)} v_{f(1)} \right) \Re \Sigma_Z^{(1)}, \quad (6)$$

$$F_{A}^{(2)} = 2 \Re \left[ \left( a_{f(0)} a_{f(2)} + |a_{f(1)}|^2 \right) \right] - a_{f(0)}^2 \Re \Sigma_Z^{(2)} - (\Re \Sigma_Z^{(1)})^2 \right],$$

$$- 2 \Re \left( a_{f(0)} a_{f(1)} \right) \Re \Sigma_Z^{(1)}, \quad (7)$$

where $v_f$ and $a_f$ are the effective vector and axial-vector couplings, respectively, which include $Z f \bar{f}$ vertex corrections and $Z \gamma$ mixing contributions. $\Sigma_Z^{(n)}$ denotes the derivative of $\Sigma_Z$, and the loop order is indicated by the subscript $(n)$.

It should be pointed out that $v_f, a_f$ and $\Sigma_Z$ as defined above include $\gamma-Z$ mixing contributions, i.e.

$$v_f(s) = v_f^Z(s) - v_f^\gamma(s) \frac{\Sigma_{\gamma Z}(s)}{s + \Sigma_{\gamma Z}(s)}, \quad (8)$$

$$a_f(s) = a_f^Z(s) - a_f^\gamma(s) \frac{\Sigma_{\gamma Z}(s)}{s + \Sigma_{\gamma Z}(s)}, \quad (9)$$

$$\Sigma_Z(s) = \Sigma_{Z Z}(s) - \frac{[\Sigma_{\gamma Z}(s)]^2}{s + \Sigma_{\gamma Z}(s)}, \quad (10)$$

$$\Sigma_{\gamma Z}(s) = \Sigma_{\gamma Z}(s) - \frac{[\Sigma_{\gamma Z}(s)]^2}{s + \Sigma_{\gamma Z}(s)}, \quad (10)$$
Here $\gamma^f$ and $\alpha^f$ are the one-particle irreducible $Zf\bar{f}$ vector and axial-vector vertex contributions, respectively, whereas $v^f$ and $a^f$ are their counterpart for the $\gamma f\bar{f}$ vertex. Furthermore, $\Sigma V_{1V_2}$ denotes the one-particle irreducible $V_1-V_2$ self-energy.

Another important quantity is the hadronic peak cross section, $\sigma^0_{\text{had}}$, which is defined as the total cross section for $e^+e^-\rightarrow (Z)\rightarrow$ hadrons for $s=M_Z^2$, after removal of $s$-channel photon exchange and box diagram contributions, as well as after the de-convolution of initial-state and initial-final interference QED effects [1,2]. The impact of the bosonic two-loop vertex corrections on $\sigma^0_{\text{had}}$ is given by [45,46]

$$\sigma^0_{\text{had}}(2) = \sum_{f=u,d,c,s,b} \frac{12\pi}{M_Z^2} \left[ \frac{\Gamma_{\text{el}}(0)}{\Gamma_{f}(0)} \left( \frac{\Gamma_{\text{el}}(2)}{\Gamma_{Z}(0)} - \frac{\Gamma_{f}(2)}{\Gamma_{Z}(0)} \right) \right].$$

The form factors $P_{V,A}^f$ are understood to include appropriate counterterms such that they are UV finite. Throughout this work, the on-shell renormalization scheme is being used, which defines all particle masses in terms of their (complex) propagator poles and the electromagnetic coupling in terms of the photon-electron vertex in the Thomson limit. A more detailed discussion of the relevant counterterms can be found in Ref. [40].

As a consequence of this renormalization scheme, the EW corrections are organized as a series in the electromagnetic coupling $\alpha$, rather than the Fermi constant $G_{\mu}$. Instead, $G_{\mu}$ will be used to compute $M_W$ within the SM, including appropriate two-loop and partial higher-loop corrections. After this step, the remaining input parameters for the prediction of the $Z$ coupling form factors are $M_Z$, $M_{t\bar{t}}$, $m_t$, $G_{\mu}$, $\alpha$, $\alpha_s$ and $\Delta\alpha$. Here $\Delta\alpha$ captures the running of the electromagnetic coupling induced by light fermion loops. It is defined through $\alpha(M_Z^2) = \alpha(0)/(1 - \Delta\alpha)$, where $\alpha(q^2)$ is the coupling at scale $q^2$. The contribution from leptons to $\Delta\alpha$ can be computed perturbatively and is known at the three-loop level [68]. $\Delta\alpha_{\text{lept}}(M_Z) \approx 0.0341976$. On the other hand, the quark contribution is non-perturbative at low scales and thus is commonly derived from experimental data. For recent evaluations of $\Delta\alpha_{\text{had}}$, see Refs. [69]. As a reference value, $\Delta\alpha_{\text{had}}^{(5)} = 0.02750$ is used in this work.

Additionally, $\Gamma_Z$ and $\Gamma_W$ are needed as inputs to convert $M_Z$ and $M_W$ to the complex pole scheme, see Eq. [8]. Furthermore, the radiator functions $R_{V,A}^f$ depend on $m_{\nu}$, $m_c$, $m_{\tau}$, and $u/d/s$ quarks can be taken as zero to very good approximation. In contrast to all other masses in this work, the MS masses are used for the bottom and charm quarks, since their on-shell counterparts are poorly defined.

3. Calculation of two-loop vertex corrections

For the calculations we followed the strategy developed in Ref. [61], where the two-loop bosonic corrections to the bottom quark weak mixing angle, $\sin^2\theta_W^{(n)}$, were obtained. In fact, the $Z\bar{b}b$ vertex is the technically most difficult case due to the larger number of mass scales in that problem compared to other flavors. Details are described there and also in [70,72]. On the other hand, for the computation of the $Z$ width we are faced not only with ratios $v^f(2)/a^f(2)$, but also with sums of powers of $v^f(2)$ and $a^f(2)$, see [6] and [7]. This leads to the occurrence of extra integrals which cancel out in the ratios $e/a$.

The complete set of two-loop diagrams required for this calculation have been generated with the computer algebra package FeynArts 3.3 [73]. They can be divided into several categories. The renormalization counterterms require two-loop self-energies with Minkowskian external momenta, $p^2 = M_Z^2 + i\varepsilon$, $M_t = M_W$, $M_Z$. In addition, there are two-loop vertex integrals with one non-vanishing external momentum squared, $s = M_Z^2 + i\varepsilon$. The two-loop self-energy integrals needed for the renormalization procedure and the vertex integrals with self-energy sub-loops have been computed using the dispersion relation technique described in Refs. [60,74,75]. The remaining bosonic two-loop diagrams amount to about one thousand integrals with a planar or non-planar vertex topology.

We did not try to reduce these integrals to a minimal set of master integrals, except for trivial cancellations of numerator and denominator terms. This means that tensors of rank $R \leq 3$ were calculated directly. For this purpose, two numerical approaches were used. Firstly, sector decomposition (SD) [76] was applied, with the packages SecDec [77,78] and FIESTA 3 [79]. Secondly, Mellin Barnes (MB) representations [80–82] were derived and evaluated with the MBsuite, consisting of software packages available at the MBtools webpage in the hepforge archive [83]: MB [84], MBresolve [85], AMBRE 1 [86], barnesroutines (D. Kosower) and PlanarityTest [87], AMBRE 2 [88] and AMBRE 3 [89], as well as MBsums [90], which are available from the AMBRE webpage [91]. The numerical package MBnumerics is being developed since 2015 [92]. It is of special importance for Minkowskian kinematics as encountered here. For the numerical integrations, MBsuite calls the CUHRE routine of the CUBA library [93,94].

Some new classes of integrals compared to the $\sin^2\theta_W^{(n)}$ case are met. They are simpler from a numerical point of view than those solved in Ref. [61]. For instance, there are various one- and two-scale integrals with internal $W$ propagators, which improves the singular threshold behaviour of integrals with only $Z$ propagators. There are altogether about one hundred integrals of this kind with different permutations of propagators, including the tensor integrals. As an example of one of the most difficult cases, the SD method for integrals from Fig. 1 in [61] gives an accuracy of up to four relevant digits. Using the MB method, these diagrams are equivalent to up to 4-dimensional MB integrals, which can be calculated efficiently with eight relevant digits by MBnumerics.

In select cases, like those described above, the MB approach is uniquely powerful. This statement applies to several hundred integrals. In the majority of integrals, though, the SD method is presently more efficient than the MB approach, mainly due to the smaller number of integration variables. For our semi-automatized calculation of massive 2-loop vertices the avail-
ability of two complementary numerical methods with a large overlap was crucial.

4. Numerical results

In this section, numerical results for bosonic two-loop corrections are compared to and combined with all other known corrections to the $Zf\bar{f}v$ vertices. These are

- Complete one-loop EW contributions (which have been re-evaluated for this work) and fermionic $O(\alpha^2)$ contributions;
- Mixed QCD-EW corrections to internal gauge-boson self-energies of order $O(\alpha_\text{ew})$ (where again we use our own re-evaluation of these terms);
- Higher-loop corrections in the large-$m_t$ limit, of order $O(\alpha_t^2\alpha_s)$, $O(\alpha_t^4)$, and $O(\alpha_t^2\alpha_s^2)$, where $\alpha_t \equiv \frac{\alpha_t}{4\pi}$ and $\alpha_t$ is the top Yukawa coupling;
- Final-state QED radiation and, for quark final states, QCD radiation up to $O(\alpha^2)$, $O(\alpha_\text{ew})$, and $O(\alpha_s^2)$, incorporated through the radiator functions $R_{V,A}$ in $\gamma$ and $4$;
- Non-factorizable $O(\alpha_\text{ew})$ vertex contributions, which cannot be written as a product of EW form factors $F_{V,A}$ and final-state radiator functions $R_{V,A}$, but instead are added separately to the formula in $\gamma$.

These are applied to a range of EWPOs: The partial $Z$ widths, $\Gamma_f \equiv \Gamma(Z \to f\bar{f})$, as well as total width, $\Gamma_Z$, various branching ratios, and the hadronic peak cross-section $\sigma_{\text{had}}$. The full electroweak two-loop corrections for the leptonic and bottom-quark asymmetries have been published previously and are not repeated here. Nevertheless, as a cross-check we reproduced the result for the leptonic asymmetry and found agreement with Refs. [43, 44] within intrinsic numerical uncertainties. Moreover, with the methods described here we can produce results for the bosonic two-loop corrections to $s_{\text{eff}}^2$ with four robust digits of precision, which exceeds the accuracy obtained with asymptotic expansions as in Ref. [43].

As discussed above, the gauge-boson mass renormalization has been performed in accordance with the complex-pole scheme in eq. $\gamma$. However, for the sake of comparison with the wider literature, the numerical results below are presented after translating to the scheme with an $s$-dependent width. In other words, results are shown for un-barred quantities, such as $\Gamma_Z$ in eq. $\gamma$.

Light fermion masses $m_f$, $f \neq t$, have been neglected throughout, except for a non-zero bottom quark mass in the $O(\alpha)$ and $O(\alpha_\text{ew})$ vertex contributions, as well as for non-zero $m_b$, $m_c$, and $m_s$ in the radiators $R_{V,A}$. The numerical input values used in this section are listed in Tab. $\gamma$.

In Table $\delta$, we show the input parameter values $\mu$ and $\mu_0$, which cannot be written as a product of EW form factors $F_{V,A}$ and final-state radiator functions $R_{V,A}$, but instead are added separately to the formula in $\gamma$. The input parameter values are listed in Table $\epsilon$.

4.1. Partial widths

Let us begin by presenting results for a fixed value of $M_W$, as input, instead of calculating $M_W$ from $G_\mu$. This more clearly illustrates the impact of the newly completed $O(\alpha_\text{ew})^2$ corrections. Table $\theta$ shows the contributions from different loop orders to the SM prediction of various partial $Z$ widths. As is evident from the table, the two-loop EW corrections are significant and larger than the current experimental uncertainty ($2.3$ GeV for $\Gamma_Z$ $\gamma$). The newly calculated bosonic corrections $O(\alpha_\text{ew})^2$ are smaller but still noteworthy. They amount to half of all known leading-three-loop QCD corrections $O(\alpha_\text{ew})$, $\alpha_t^2\alpha_s^2$, $\alpha_t^2\alpha_s^2$, $\alpha_t^2\alpha_s^2$, with the latter enhanced by powers of $\alpha_t$, $\alpha_s$, and $N_f$.

Table $\theta$ shows the SM predictions obtained if one uses $\mu$ as an input to compute $M_W$, based on the results of $\mu$, $\mu_0$, $\alpha_s(M_Z)$, $\alpha_\text{eff}$, and $\Lambda(\alpha_\text{ew})^2$ corrections. Each line of the table adds an additional order of perturbation theory to the previous line, using the same order for the $Zf\bar{f}$ vertex corrections and the calculation of the $W$ mass $\gamma$. The $O(\alpha_\text{ew})$ correction to $\Gamma_Z$, corresponding to the difference between the last two rows in Table $\theta$, amounts to $0.34$ MeV, which is more than three times larger than its previous estimation $\mu$. An updated discussion on how this knowledge changes the intrinsic error estimations will be given in section $\mu$.

4.2. Ratios

The experimental results from LEP and SLC are typically not presented in terms of partial widths for the different final

Note that the value in the next-to-last line of Tab $\theta$ differs slightly from Ref. [46]. This is because in Ref. [46] the “best value” prediction of $M_W$ was carried with the full (fermionic plus bosonic) EW two-loop predictions included. Here, however, we are interested in a clear distinction of fermionic and bosonic two-loop terms in all contributions, including the $M_W$ prediction.
be conveniently expressed in terms of simple parameterization formulae. The coefficients of these formulæ have been fitted to the full calculation results on a grid that spans the currently allowed experimental ranges for each input parameter. Here the full calculation includes all higher-order corrections listed as the beginning of section 4 for the partial widths, branching ratios and the peak cross-sections, and with $M_W$ calculated from $G_μ$ to the same precision.

For all EWPOs reported here, the same form of parameterization formula is utilized:

$$X = X_0 + c_1 \Delta M + c_2 \Delta t + c_3 \Delta m_s + c_4 \Delta^2 \alpha_s + c_5 \Delta \alpha + c_6 \Delta \alpha + c_7 \Delta \Delta Z,$$

where $X = \sigma_{\text{had}}$, $\Delta M = (M_{Z\ell} - M_{Z0})$, and $\Delta m_s$ are the shifts on $M_W$, $m_s$, and $\alpha_s$, respectively. The coefficients $c_1, c_2, c_3, c_4, c_5, c_6, c_7$ are fixed values.

5. Error estimates

In addition to the dependence on the input parameters, the accuracy of the results presented here is limited by unknown

$\Delta Z = \frac{M_Z}{91.1876 \text{ GeV}} - 1$. 

As before, $M_H, M_Z, m_t$ and $\alpha_s$ are defined in the on-shell scheme, using the $s$-dependent width scheme for $M_Z$ (to match the published experimental values), while $\alpha_s$ is defined in the MS scheme. The dependence on $m_t$, $m_c$, and $m_s$ is negligible within the allowed ranges for these quantities.

The fit values of the coefficients for the different EWPOs are given in Tab. 5. With these parameters, the formulæ provide very good approximations to the full results within the ranges $M_H = 125.1 \pm 5.0 \text{ GeV}$, $m_t = 173.2 \pm 4.0 \text{ GeV}$, $\alpha_s = 0.1184 \pm 0.0050$, $\Delta \alpha = 0.0590 \pm 0.0005$, and $M_Z = 91.1876 \pm 0.0042 \text{ GeV}$, with maximal deviations as quoted in the last column of Tab. 5. As can be seen from the latter, the accuracies of the fit formulæ are sufficient for the foreseeable future.

5. Error estimates

In addition to the dependence on the input parameters, the accuracy of the results presented here is limited by unknown

$\Delta Z = \frac{M_Z}{91.1876 \text{ GeV}} - 1$. 

As before, $M_H, M_Z, m_t$ and $\alpha_s$ are defined in the on-shell scheme, using the $s$-dependent width scheme for $M_Z$ (to match the published experimental values), while $\alpha_s$ is defined in the MS scheme. The dependence on $m_t$, $m_c$, and $m_s$ is negligible within the allowed ranges for these quantities.

The fit values of the coefficients for the different EWPOs are given in Tab. 5. With these parameters, the formulæ provide very good approximations to the full results within the ranges $M_H = 125.1 \pm 5.0 \text{ GeV}$, $m_t = 173.2 \pm 4.0 \text{ GeV}$, $\alpha_s = 0.1184 \pm 0.0050$, $\Delta \alpha = 0.0590 \pm 0.0005$, and $M_Z = 91.1876 \pm 0.0042 \text{ GeV}$, with maximal deviations as quoted in the last column of Tab. 5. As can be seen from the latter, the accuracies of the fit formulæ are sufficient for the foreseeable future.

5. Error estimates

In addition to the dependence on the input parameters, the accuracy of the results presented here is limited by unknown

$\Delta Z = \frac{M_Z}{91.1876 \text{ GeV}} - 1$. 

As before, $M_H, M_Z, m_t$ and $\alpha_s$ are defined in the on-shell scheme, using the $s$-dependent width scheme for $M_Z$ (to match the published experimental values), while $\alpha_s$ is defined in the MS scheme. The dependence on $m_t$, $m_c$, and $m_s$ is negligible within the allowed ranges for these quantities.

The fit values of the coefficients for the different EWPOs are given in Tab. 5. With these parameters, the formulæ provide very good approximations to the full results within the ranges $M_H = 125.1 \pm 5.0 \text{ GeV}$, $m_t = 173.2 \pm 4.0 \text{ GeV}$, $\alpha_s = 0.1184 \pm 0.0042$, $\Delta \alpha = 0.0590 \pm 0.0005$, and $M_Z = 91.1876 \pm 0.0042 \text{ GeV}$, with maximal deviations as quoted in the last column of Tab. 5. As can be seen from the latter, the accuracies of the fit formulæ are sufficient for the foreseeable future.
three- and four-loop contributions. The numerically leading missing pieces are the $O(\alpha^3)$, $O(\alpha^2\alpha_s)$, $O(\alpha\alpha_s^2)$ and $O(\alpha\alpha_s^3)$ corrections beyond the known leading $y^\mu$ terms from Refs. [47-53].

Following Refs. [46,102], the size of these terms may be estimated by assuming that the perturbation series approximately is a geometric series. In this way one obtains

$$O(\alpha^3) - O(\alpha_s^3) \sim \frac{O(\alpha^3) - O(\alpha_s^2)}{O(\alpha)} O(\alpha^2),$$

$$O(\alpha^2\alpha_s) - O(\alpha_s^2\alpha_s) \sim \frac{O(\alpha^2\alpha_s) - O(\alpha_s^2)}{O(\alpha)} O(\alpha_s),$$

$$O(\alpha\alpha_s^2) - O(\alpha_s\alpha_s^2) \sim \frac{O(\alpha\alpha_s^2) - O(\alpha_s\alpha_s)}{O(\alpha)} O(\alpha_s),$$

$$O(\alpha\alpha_s^3) - O(\alpha_s\alpha_s^3) \sim \frac{O(\alpha\alpha_s^3) - O(\alpha_s\alpha_s^2)}{O(\alpha)} O(\alpha_s),$$

where the known leading large-$n_t$ approximations have been subtracted in the numerators. For the example of the total $Z$ width, these expressions lead to

$$\Gamma_Z : \ O(\alpha^3) - O(\alpha_s^3) \sim 0.20 \text{ MeV},$$

$$O(\alpha^2\alpha_s) - O(\alpha_s^2\alpha_s) \sim 0.21 \text{ MeV},$$

$$O(\alpha\alpha_s^2) - O(\alpha_s\alpha_s^2) \sim 0.23 \text{ MeV},$$

$$O(\alpha\alpha_s^3) - O(\alpha_s\alpha_s^3) \sim 0.35 \text{ MeV}. \quad (15)$$

An additional source of theoretical uncertainty stems from the unknown $O(\alpha_s^2)$ final-state QCD corrections and three-loop mixed QED/QCD final-state corrections of order $O(\alpha\alpha_s^2)$ and $O(\alpha_s^2\alpha_s)$. In [46] they were found to be sub-dominant, and the estimates can be taken over from there without change. Combining these findings with eqs. [15] in quadrature, the total theory error adds up to $\Delta \Gamma_Z \approx 0.4$ MeV. Compared to the previous theory error estimate $\delta \Gamma_Z \approx 0.5$ MeV [46] one observes a slight decrease due to the knowledge of the bosonic corrections calculated in this work.

In addition to the elimination of an uncertainty associated with the previous unknown $O(\alpha_s^2\alpha_s)$ corrections, the values in the first and second rows of [15] also shifted since the full $O(\alpha^2)$ corrections used in [14] were not available before. These shifts conspire to result in a reduction of the uncertainty estimate for these two error sources.

### Table 4: Results for the ratios $R_L$, $R_c$ and $R_b$, with $M_W$ calculated from $G_\mu$ to the same order as indicated in each line. In all cases, the complete radiator functions $R_{V,A}$ are included.

| Observable | $X_0$ | $c_1$ | $c_2$ | $c_3$ | $c_4$ | $c_5$ | $c_6$ | $c_7$ | $R_L$ | $R_c$ | $R_b$ |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| $\Gamma_{e,\mu}$ [MeV] | 83.983 | 0.061 | 0.810 | 0.096 | 0.01 | 0.25 | -1.1 | 286 | < 0.001 |
| $\Gamma_z$ [MeV] | 83.793 | -0.060 | 0.810 | -0.095 | 0.01 | -0.25 | -1.1 | 285 | < 0.001 |
| $\Gamma_v$ [MeV] | 167.176 | -0.071 | 1.26 | -0.19 | 0.02 | -0.36 | -0.1 | 504 | < 0.001 |
| $\Gamma_u$ [MeV] | 299.993 | -0.38 | 4.08 | 14.27 | 1.6 | 1.8 | -11.1 | 1253 | < 0.002 |
| $\Gamma_c$ [MeV] | 299.916 | -0.38 | 4.08 | 14.27 | 1.6 | 1.8 | -11.1 | 1253 | < 0.002 |
| $\Gamma_{d,s}$ [MeV] | 382.828 | -0.39 | 3.83 | 10.20 | -2.4 | 0.67 | -10.1 | 1470 | < 0.002 |
| $\Gamma_b$ [MeV] | 375.889 | -0.36 | -2.14 | 10.53 | -2.4 | 1.2 | -10.1 | 1459 | < 0.006 |
| $\Gamma_Z$ [MeV] | 2494.74 | -2.3 | 19.9 | 58.61 | -4.0 | 8.0 | -56.0 | 9273 | < 0.012 |
| $R_L$ [10^{-3}] | 2075.16 | -7.8 | -37 | 732.3 | -44 | 5.5 | -358 | 11696 | < 0.1 |
| $R_c$ [10^{-3}] | 172.22 | -0.031 | 1.0 | 2.3 | 1.3 | 0.38 | -1.2 | 37 | < 0.01 |
| $R_b$ [10^{-3}] | 215.85 | 0.029 | -2.92 | 1.32 | -0.84 | 0.032 | 0.72 | -18 | < 0.01 |

### Table 5: Coefficients for the parameterization formula [13] for various observables ($X_i$). Within the ranges $M_{Z_1} = 125.1 \pm 5.0 \text{ GeV}$, $m_t = 173.2 \pm 4.0 \text{ GeV}$, $\alpha_s = 0.1184 \pm 0.0050$, $\Delta \alpha = 0.0590 \pm 0.0005$ and $M_Z = 91.1876 \pm 0.0042 \text{ GeV}$, the formulae approximate the full results with maximal deviations given in the last column.
At this point we should mention that we did not consider the theoretical efforts needed to unfold the large QED corrections from the measured real cross sections in the $Z$ peak region and to extract the EWPOs studied here in detail. For LEP, this was based on tools such as the ZFITTER package \cite{103,105} and was discussed carefully e. g. in Refs. \cite{1,2,106}. The correct unfolding framework for extracting $Z \rightarrow 2$ observables at accuracies amounting to about 1/20 of the LEP era certainly has to rely on the correct treatment of Laurent series for the $Z$ line shape as is discussed e. g. in \cite{107,110}.

The 1-loop corrections to the $Z$ boson parameters were determined in the 1980s \cite{17}. Today, 33 years later, while the present study finalizes the determination of the electroweak two-loop corrections to the $Z$-boson parameters, we are already faced with the need of more precision in the future.

Table 6: Theory uncertainty estimates for the partial and total $Z$ widths and branching ratios from missing 3-loop and higher orders. See text for details.

| $\Gamma_{\ell,\mu,\tau}$ | 0.018 MeV | $\Gamma_{\mu,c}$ | 0.11 MeV | $R_{\ell}$ | $6 \cdot 10^{-3}$ |
| $\Gamma_{\nu}$ | 0.016 MeV | $\Gamma_{b}$ | 0.18 MeV | $R_{c}$ | $5 \cdot 10^{-5}$ |
| $\Gamma_{d,s}$ | 0.08 MeV | $\Gamma_{Z}$ | 0.4 MeV | $R_{b}$ | $1 \cdot 10^{-4}$ |

The corresponding error estimates for the partial widths are shown in Table 6. For the ratios ($R_{\ell}$, $R_{c}$ and $R_{b}$), the theory uncertainty has been estimated from the partial widths using simple Gaussian error propagation.

The theory uncertainty for the hadronic peak cross-section is dominated by a non-factorizable contribution stemming from the imaginary part of the $Z$-boson self-energy $\delta\sigma_{\text{had}}$. This non-factorizable term does not receive any bosonic two-loop corrections, so that the error estimate can be taken from Ref. \cite{46} without change:

$$\delta\sigma_{\text{had}} = O(\alpha^3) \approx 3.7 \text{ pb}, \quad O(\alpha^2 \alpha_s) \approx 4.2 \text{ pb}. \quad (16)$$

Adding these in quadrature leads to the overall uncertainty estimate of $\delta\sigma_{\text{had}} \approx 6 \text{ pb}$.

6. Summary

In this work the bosonic two-loop electroweak corrections, $O(\alpha^2)$, to $Z$ boson production and decay parameters are presented for the first time. These corrections are comparable in size to the leading three-loop corrections of $O(\alpha_3^2)$, $O(\alpha_3^3)$, $O(\alpha_3^4)$, $O(\alpha_3^5)$. This is especially pronounced for $\Gamma_{b}$, see Tab. 2 and for $\sigma_{\text{had}}$, see Tab. 3. The bosonic corrections shift the value of $\Gamma_{Z}$ by 0.51 MeV when using $M_{W}$ as input and 0.34 MeV when using $G_{\mu}$ as input, which is large from the point of view of future colliders. The most ambitious FCC-ee project expects an accuracy of 0.1 MeV. Similarly, the bosonic corrections are important for $R_{b}$, see Tab. 3. Due to the high accuracy of the numerical loop integrations, the results obtained here are stable enough even in the context of potential future experimental precisions.

Updated theory error estimates are given, which are slightly reduced due to the newly available full two-loop corrections. We expect that the numerical integration methods used here can be extended to compute the full three-loop corrections to $Z$-pole EWPOs. For a more detailed discussion of future projections, see Ref. \cite{6,8}. However, this is very demanding and needs more effort and resources. Further, at this level of complexity independent cross-checks by different groups, using independent calculations and approaches, are welcome.

It should be noted that the $O(\alpha_3^0)$ correction for the total $Z$ decay width appears to be relatively large compared to previous estimates based on the knowledge of the lower order result $O(\alpha_3^0)$. A similar observation concerns the bosonic two-loop corrections to $A_{b}$. This means that all estimations at this level of accuracy should be taken with a grain of salt. Therefore, explicit calculations are important even for contributions that were previously estimated to be subdominant.

The experimental precision at LEP is dominated by a non-factorizable contribution stemming from the imaginary part of the $Z$-boson self-energy $\delta\sigma_{\text{had}}$. This non-factorizable term does not receive any bosonic two-loop corrections, so that the error estimate can be taken from Ref. \cite{46} without change.
