We compute in linearized gravity all the contributions to the gravitational effective action due to a virtual Dirac fermion, related to the conformal anomaly. This requires, in perturbation theory, the identification of the gauge-gauge-graviton vertex off mass shell, involving the correlator of the energy-momentum tensor and two vector currents (TJJ), which is responsible for the generation of the gauge contributions to the conformal anomaly in gravity. We also present the anomalous effective action expanded in the inverse mass of the fermion as in the Euler-Heisenberg case.

I. INTRODUCTION

Investigations of conformal anomalies in gravity (see [1] for an historical overview and references) [2] and in gauge theories [3–5] as well as in string theory, have been of remarkable significance along the years. In cosmology, for instance [6], (see also [7] for an overview) the study of the gravitational trace anomaly has been performed in an attempt to solve the problem of the “graceful exit” (see for instance [8–11]). In other analysis it has been pointed out that the conformal anomaly may prevent the future singularity occurrence in various dark energy models [12,13].

In the past the analysis of the formal structure of the effective action for gravity in four dimensions, obtained by integration of the trace anomaly [14,15], has received a special attention, showing that the variational solution of the anomaly equation, which is nonlocal, can be made local by the introduction of extra scalar fields. The gauge contributions to these anomalies are identified at 1-loop level from a set of diagrams—involving fermion loops with two external gauge lines and one graviton line—and are characterized, as shown recently by Giannotti and Mottola in [16], by the presence of anomaly poles. Anomaly poles are familiar from the study of the chiral anomaly in gauge theories and describe the nonlocal structure of the effective action. In the case of global anomalies, as in QCD chiral dynamics, they signal the presence of a nonperturbative phase of the fundamental theory, with composite degrees of freedom (pions) which offer an equivalent description of the fundamental Lagrangian, matching the anomaly, in agreement with ‘t Hooft’s principle. Previous studies of the role of the conformal anomaly in cosmology concerning the production of massless gauge particles and the identification of the infrared anomaly pole are those of Dolgov [17,18], while a discussion of the infrared pole from a dispersive derivation is contained in [19].

In a related work [20] we have shown that anomaly poles are typical of the perturbative description of the chiral anomaly not just in some special kinematical conditions, for instance in the collinear region, where the coupling of the anomalous gauge current to two (on shell) vector currents (for the AVV diagram) involves a pseudoscalar intermediate state (with a collinear and massless fermion-antifermion pair) but under any kinematical conditions. They are the most direct—and probably also the most significant—manifestation of the anomaly in the perturbative diagrammatic expansion of the effective action. On a more speculative side, the interpretation of the pole in terms of composite degrees of freedom could probably have direct physical implications, including the condensation of the composite fields, very much like Bose Einstein (BE) condensation of the pion field, under the action of gravity. Interestingly, in a recent paper, Sikivie and Yang have pointed out that Peccei-Quinn axions (PQ) may form BE condensates [21]. With these motivations in mind, in this work, which parallels a previous investigation of the chiral gauge anomaly [20], we study the perturbative structure of the off-shell effective action showing the appearance of similar singularities under general kinematical conditions. Our investigation is a first step towards the computation of the exact effective action describing the coupling of the standard model to gravity via the conformal anomaly, that we hope to discuss in the future.

In our study we follow closely the work of [16]. There the authors have presented a complete off-shell classification of the invariant amplitudes of the relevant correlator responsible for the conformal anomaly, which involves the energy-momentum tensor (T) and two vector currents (J), TJJ, and have thoroughly investigated it in the QED case, drawing on the analogy with the case of the chiral anomaly. The analysis of [16] is based on the use of dispersion relations, which are sufficient to identify the anomaly poles of the amplitude from the spectral density of this correlator.

*roberta.armillis@le.infn.it
†claudio.coriano@le.infn.it
‡luigi.dellerose@le.infn.it
but not to characterize completely the off-shell effective action of the theory and the remaining nonconformal contributions, which will be discussed in this paper. The poles that we extract from the complete effective action include both the usual poles derived from the spectral analysis of the diagrams, which are coupled in the infrared (IR) and other extra poles which account for the anomaly but are decoupled in the same limit. These extra poles appear under general kinematic configurations and are typical of the off-shell as well as of the on-shell effective action, both for massive and massless fermions.

We also show, in agreement with that analysis, that the pole terms which contribute to the conformal anomaly are indeed only obtained in the on-shell limit of the external gauge lines, and identify all the mass corrections to the correlator in the general case. This analysis is obtained by working out all the relevant kinematical limits of the perturbative corrections. We present the complete anomalous off-shell effective action describing the interaction of gravity with the photons, written in a form in which we separate the nonlocal contribution due to the anomaly pole from the rest of the action (those which are conformally invariant in the massless fermion limit). Away from the conformal limit of the theory we present a 1/m expansion of the effective action as in the Euler-Heisenberg approach. This expansion, naturally, does not convey the presence of nonlocalities in the effective action due to the appearance of massless poles.

The computation of similar diagrams, for the on-shell photon case, appears in older contributions by Berends and Gastmans [22] using dimensional regularization, in their study of the gravitational scattering of photons and by Milton using Schwinger’s methods [23]. The presence of an anomaly pole in the amplitude has not been investigated nor noticed in these previous analysis, since it does not appear explicitly in their results, nor the 1/m expansion of the three form factors of the on-shell vertex, contained in [22], allows its identification in the S-matrix elements of the theory. Two related analysis by Drummond and Hatherell in their investigation of the gravitational contribution to the self-energy of the photon [24] and the renormalization of the trace anomaly [25] included the same on-shell vertex. Later, this same vertex has provided the ground for several elaborations concerning a possible superluminal behavior of the photon in the presence of an external gravitational field [26].

II. THE CONFORMAL ANOMALY AND GRAVITY

In this section we briefly summarize some basic and well known aspects of the trace anomaly in quantum gravity and, in particular, the identification of the nonlocal action whose variation generates a given trace anomaly.

We recall that the gravitational trace anomaly in 4 space-time dimensions generated by quantum effects in a classical gravitational and electromagnetic background is given by the expression

$$T_\mu^\nu = -\frac{1}{8} \left[ 2bC^2 + 2b\left( E - \frac{2}{3} \Box R \right) + 2cF^2 \right].$$

where $b$, $b'$ and $c$ are parameters that for a single fermion in the theory result $b = 1/320\pi^2$, $b' = -11/5760\pi^2$, and $c = -\epsilon^2/24\pi^2$; furthermore $C^2$ denotes the Weyl tensor squared and $E$ is the Euler density given by

$$C^2 = C_{\lambda\mu\nu\rho}C^{\lambda\mu\nu\rho} = R_{\lambda\mu\nu\rho}R^{\lambda\mu\nu\rho} - 2R_{\mu\nu}R^{\mu\nu} + \frac{R^2}{3}$$

(2)

$$E = *R_{\lambda\mu\nu\rho} *R^{\lambda\mu\nu\rho} = R_{\lambda\mu\nu\rho}R^{\lambda\mu\nu\rho} - 4R_{\mu\nu}R^{\mu\nu} + R^2.$$

(3)

The effective action is identified by solving the following variational equation by inspection

$$-\frac{2}{\sqrt{g}} g_{\mu\nu} \delta \Gamma = T_\mu^\nu.$$  

(4)

Its solution is well known and is given by the nonlocal expression

$$S_{\text{anom}}[g, A] = \frac{1}{8} \int d^4x \sqrt{-g} \int d^4x' \sqrt{-g'} \left( E - \frac{2}{3} \Box R \right) x$$

$$\times G_4(x, x') \left[ 2bC^2 + b\left( E - \frac{2}{3} \Box R \right) + 2cF_{\mu\nu}F^{\mu\nu} \right] x'.$$

(5)

Notice that we are omitting $\frac{1}{\sqrt{g}} R^2$ terms which are not necessary at one-loop level. The notation $G_4(x, x')$ denotes the Green’s function of the differential operator defined by

$$\Delta_4 = \nabla_\mu \left( \nabla_\nu \nabla_\nu + 2R_{\mu\nu} - \frac{2}{3} R g^{\mu\nu} \right) \nabla_\nu$$

$$= \Box^2 + 2R_{\mu\nu} \nabla_\mu \nabla_\nu + \frac{1}{3} \left( \nabla_\mu R \right) \nabla_\nu - \frac{2}{3} R \Box$$

(6)

and requires some boundary conditions to be specified. This operator is conformally covariant, in fact under a rescaling of the metric one can show that

$$g_{\mu\nu} \to \Delta_4 = e^{-2\sigma} \Delta_4.$$

(7)

Notice that the general solution of (4) involves, in principle, also a conformally invariant part that is not identified by this method. As in Ref. [16], we concentrate on the contribution proportional to $F^2$ and perform an expansion of this term for a weak gravitational field and drop from this action all the terms which are at least quadratic in the deviation of the metric from flat space

$$g_{\mu\nu} = \eta_{\mu\nu} + \kappa h_{\mu\nu} \quad \kappa^2 = 16\pi G,$$

(8)

with $G$ the gravitational constant. The nonlocal action reduces to
valid for a weak gravitational field. In this case
\begin{equation}
R^{(1)}_x = \partial^2_{\mu} \partial^2_{\nu} h_{\mu\nu} - \partial h_{\mu\nu}, \quad h = \eta_{\mu\nu} h_{\mu\nu}.
\end{equation}

The presence of the Green’s function of the \( \Box \) operator in Eq. (9) is the clear indication that the solution of the anomaly equation is characterized by an anomaly pole. In the next sections we are going to perform a direct diagrammatic computation of this action and reobtain from it the pole contribution identified in the dispersive analysis of [16] and the conformal invariant extra terms which are not present in (9). We start with an analysis of the correlator following an approach which is close to that followed in Ref. [16]. The crucial point of the derivation presented in that work is the imposition of the Ward identity for the \( TJJ \) correlator [see Eq. (42) below] which allows to eliminate all the Schwinger (gradients) terms which otherwise plague any derivation based on the canonical formalism and are generated by the equal-time commutator of the energy-momentum tensor with the vector currents. In reality, this approach can be bypassed by just imposing at a diagrammatic level the validity of an operatorial relation for the trace anomaly, evaluated at a nonzero momentum transfer, together with the conservation of the vector currents on the other two vector vertices of the correlator.

III. THE CONSTRUCTION OF THE FULL AMPLITUDE \( \Gamma^{\mu\nu\alpha\beta}(p, q) \)

We consider the standard QED Lagrangian
\begin{equation}
\mathcal{L} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} + i \bar{\psi} \gamma^\mu (\partial_\mu - ieA_\mu) \psi - m \bar{\psi} \psi,
\end{equation}
with the energy-momentum tensor split into the free fermionic part \( T_f \), the interacting fermion-photon part \( T_{fp} \) and the photon contribution \( T_{ph} \) which are given by
\begin{align}
T_f^{\mu\nu} &= -i \bar{\psi} \gamma^{\nu} \partial_\mu \psi + g^{\mu\nu} (i \bar{\psi} \gamma^\lambda \partial_\lambda \psi - m \bar{\psi} \psi), \\
T_{fp}^{\mu\nu} &= -e J^{(\mu} A^{\nu)} + eg^{\mu\nu} J A_\nu, \\
T_{ph}^{\mu\nu} &= F^{\mu\lambda} F_{\nu}^{\lambda} - \frac{1}{4} g^{\mu\nu} F^{\lambda\rho} F_{\lambda\rho},
\end{align}
where the current is defined as
\begin{equation}
J^\mu(x) = \bar{\psi}(x) \gamma^\mu \psi(x).
\end{equation}

In the coupling to gravity of the total energy-momentum tensor
which generates the diagrams (b) and (c) shown in Fig. 1, respectively, called the “triangle” and the “t-p-bubble” (“t-” stays for tensor), together with the two ones obtained for the exchange of $p$ with $q$ and $\alpha$ with $\beta$.

The conformal anomaly appears in the perturbative expansion of $T_p$ and involves these four diagrams. The electromagnetic contribution is responsible for other two diagrams whose invariant amplitudes are well-defined and will be used to fix the ill-defined amplitudes present in the tensor expansion of $T_p$ by using a Ward identity.

The lowest order contribution is obtained, in the background field formalism, from Maxwell’s e.m. tensor, and is given by

$$S_{\mu\nu\alpha\beta} = \frac{\delta^2 \langle T_{\mu\nu}^{\mu\nu}(z) \rangle}{\delta A_\mu(x) \delta A_\rho(y)} \bigg|_{A=0}. \quad (26)$$

Equivalently, it can be obtained from the matrix element

$$\langle 0 | T_{\mu\nu}^{\mu\nu} | \gamma \gamma \rangle \quad (27)$$

which allows to identify the vertex in momentum space. Using (26) we easily obtain

$$S_{\mu\nu\alpha\beta}(z,x,y) = 2g_{\alpha\beta} \partial(\mu \partial z_\nu \partial y_\alpha - 2g_{\alpha\nu} \partial z_\mu \partial y_\alpha - 2g_{\nu\alpha} \partial z_\mu \partial y_\nu + g_{\alpha\nu} \partial z_\mu \partial y_\mu + g_{\nu\alpha} \partial z_\mu \partial y_\nu)$$

$$- 2g_{\alpha\nu} \partial z_\mu \partial y_\mu + g_{\nu\alpha} \partial z_\mu \partial y_\nu - \partial \partial_{\mu} \partial \partial_{\nu} \partial \partial_{\alpha} \partial \partial_{\beta} + \partial \partial_{\alpha} \partial \partial_{\beta} \partial \partial_{\mu} \partial \partial_{\nu} + \partial \partial_{\mu} \partial \partial_{\nu} \partial \partial_{\alpha} \partial \partial_{\beta}$$

$$- \partial \partial_{\alpha} \partial \partial_{\beta} \partial \partial_{\mu} \partial \partial_{\nu} \quad (28)$$

where $\partial \partial_{\mu} \partial \partial_{\nu} \partial \partial_{\alpha} \partial \partial_{\beta} \equiv \partial / \partial x^\mu \partial x^\nu \partial x^\alpha \partial x^\beta (x-z)$ and so on. In momentum space this lowest order vertex is given by

$$S_{\mu\nu\alpha\beta} = (p^\mu q^\nu + p^\nu q^\mu) g_{\alpha\beta} + p \cdot q (g_{\alpha\beta} g_{\mu\nu} + g_{\alpha\mu} g_{\beta\nu})$$

$$- g_{\mu\nu} (p \cdot q g_{\alpha\beta} - q^\alpha p^\beta) - (g_{\beta\nu} p^\mu + g_{\beta\mu} p^\nu) q^\alpha - (g_{\alpha\nu} q^\mu + g_{\alpha\mu} q^\nu) p^\beta. \quad (29)$$

The corresponding vertices which appear, respectively, in the triangle diagram and on the t-bubble at $O(e^2)$ are given by

$$V_{\mu\nu\rho}(k_1, k_2) = \frac{1}{4} \left[ g_{\alpha\beta} (k_1 + k_2) \gamma^\alpha (k_1 + k_2) \alpha \right]$$

$$- \frac{1}{2} g_{\alpha\nu} \left[ g_{\beta\alpha} \gamma^\nu \gamma^\beta + g_{\alpha\nu} \gamma^\nu \right], \quad (30)$$

$$W_{\mu\nu\rho} = \frac{1}{2} \left( g_{\mu\rho} g_{\nu\sigma} + g_{\nu\rho} g_{\mu\sigma} + g_{\mu\nu} g_{\rho\sigma} \right), \quad (31)$$

where $k_1(k_2)$ is outcoming (incoming). Using the two vertices $V_{\mu\nu\rho}(k_1, k_2)$ and $W_{\mu\nu\rho}$ we obtain for the diagrams (b) and (c) of Fig. 1

$$V_{\mu\nu\rho}(p, q) = -(-ie^2/3) \int \frac{d^4l}{(2\pi)^4} \text{tr} \left[ V_{\mu\nu\rho}(l + p, l - q) \gamma^\beta (l + q + m) \gamma^\delta (l + m) \right]$$

$$\frac{[l^2 - m^2][l^2 - (l - q)^2 - m^2][l^2 + (l + p)^2 - m^2]}{[l^2 - m^2][l^2 - (l - q)^2 - m^2][l^2 + (l + p)^2 - m^2]}, \quad (32)$$

so that the one-loop amplitude in Fig. 1 results

$$\Gamma_{\mu\nu\rho}(p, q) = V_{\mu\nu\rho}(p, q) + V_{\mu\rho\alpha}(q, p)$$

$$+ W_{\mu\nu\rho}(p, q) + W_{\mu\rho\alpha}(q, p). \quad (34)$$

The bare Ward identity which allows to define the divergent amplitudes that contribute to the anomaly in $\Gamma$ in terms of the remaining finite ones is obtained by reexpress-
ing the classical equation
\[ \partial_\nu T_{\mu \nu}^{ph} = -F_{\mu \nu} J_\nu \] (35)
as an equation of generating functionals in the background electromagnetic field
\[ \partial_\nu \langle T_{\mu \nu}^{ph} \rangle_A = -F_{\mu \nu} \langle J_\nu \rangle_A, \] (36)
which can be expanded perturbatively as
\[ \partial_\nu \langle T_{\mu \nu}^{ph} \rangle_A = -F_{\mu \nu} \left( J_\nu \int d^4w(i\epsilon) J \cdot A(w) \right). \] (37)
Notice that we have omitted the first term in the Dyson’s series of \( \langle J_\nu \rangle_A \), shown on the right-hand side (rhs) of (37) since \( \langle J_\nu \rangle = 0 \). The bare Ward identity then takes the form
\[ \partial_\nu \Gamma^{\mu \nu \alpha \beta} = \frac{\delta^2(F^{\mu \lambda}(z)(J_A(z)))_A}{\delta A_\alpha(x) \delta A_\beta(y)} \bigg|_{\lambda \rightarrow 0} \] (38)
which takes contribution only from the first term on the rhs of Eq. (37). For this we use the definition of the vacuum polarization
\[ \Pi^{\alpha \beta}(x, y) = -ie^2 \langle J_\alpha(x) J_\beta(y) \rangle, \] (39)
or
\[ \Pi^{\alpha \beta}(p) = -i^2(-ie)^2 \int \frac{d^4l}{(2\pi)^4} \times \text{tr}\{\gamma^\alpha\gamma^\beta(l + p)\}
\times \left[ \frac{1}{(l^2 - m^2)(l^2 - m^2)} \right]
= (p^2 g^{\alpha \beta} - p_\alpha p_\beta) \Pi(p^2, m^2) \] (40)
with
\[ \Pi(p^2, m^2) = \frac{e^2}{36\pi^2 p^2} \left[ 6A_0(m^2) + p^2 - 6m^2 - 3B_0(p^2, m^2) \right], \] (41)
which obviously satisfies the Ward identity \( p_\alpha \Pi^{\alpha \beta}(p) = 0 \). The expressions of the \( A_0 \) and \( B_0 \) contributions are given in Appendix A.

Using these definitions, the unrenormalized Ward identity which allows to completely characterize the form of the correlator in momentum space becomes
\[ k_\nu \Gamma^{\mu \nu \alpha \beta}(p, q) = (q^\mu p^\alpha p^\beta - q^\mu g^{\alpha \beta} p^2 + g^{\alpha \beta} q^2) \] \[ - g^{\mu \beta} p^\alpha p \cdot q \Pi(p^2) \] \[ + (p^\mu q^\alpha q^\beta - p^\mu g^{\alpha \beta} q^2 + g^{\mu \alpha} p^\beta q^2) \] \[ - g^{\alpha \beta} q^\mu p \cdot q \Pi(q^2). \] (42)

A. Tensor expansion and invariant amplitudes of \( \Gamma \)

The full one-loop amplitude \( \Gamma \) can be expanded on the basis provided by the 43 monomial tensors listed in Table I
\[ \Gamma^{\mu \nu \alpha \beta}(p, q) = \sum_{i=1}^{43} A_i(k^2, p^2, q^2) T_i^{\mu \nu \alpha \beta}(p, q). \] (43)

Since the amplitude \( \Gamma^{\mu \nu \alpha \beta}(p, q) \) has total mass dimension equal to 2 it is obvious that not all the coefficients \( A_i \) are convergent. They can be divided into 3 groups:

1. \( A_1 \leq A_i \leq A_{16} \)—multiplied by a product of four momenta, they have mass dimension -2 and therefore are UV finite;
2. \( A_{17} \leq A_i \leq A_{42} \)—these have mass dimension 2 since the four Lorentz indices of the amplitude are carried by two metric tensors
3. \( A_{20} \leq A_i \leq A_{43} \)—they appear next to a metric tensor and two momenta, have mass dimension 0 and are divergent.

The way in which the 43 invariant amplitudes in Eq. (43) will be managed in order to reduce them to the 13 ones named \( F_i(k^2, p^2, q^2) \) is the subject of this section. The reduction is accomplished in 4 different steps and has as a guiding principle the elimination of the divergent amplitudes \( A_i \) in terms of the convergent ones after imposing some conditions on the whole amplitude. We require

(a) the symmetry in the two indices \( \mu \) and \( \nu \) of the symmetric energy-momentum tensor \( T^{\mu \nu} \);

(b) the conservation of the two vector currents on \( p^\alpha \) and \( q^\beta \);

(c) the Ward identity on the vertex with the incoming momentum \( k \) defined above in Eq. (42).

Condition (a) becomes
\[ \Gamma^{\mu \nu \alpha \beta}(p, q) = \Gamma^{\nu \mu \alpha \beta}(p, q). \] (44)

TABLE I. The 43 tensor monomials named \( T_i^{\mu \nu \alpha \beta}(p, q) \) in Eq. (43) built up from the metric tensor and the two independent momenta \( p \) and \( q \) into which a general fourth rank tensor can be expanded.

| \( p^\mu p^\nu p^\alpha p^\beta \) | \( p^\mu p^\nu p^\alpha q^\beta \) | \( p^\mu p^\nu q^\alpha p^\beta \) | \( p^\mu q^\nu q^\alpha p^\beta \) | \( p^\mu q^\nu q^\alpha q^\beta \) | \( g^{\mu \nu} g^{\alpha \beta} \) |
|\( q^\alpha q^\beta p^\mu p^\nu \) | \( q^\alpha q^\beta p^\mu q^\nu \) | \( q^\alpha q^\beta q^\mu p^\nu \) | \( q^\alpha q^\beta q^\mu q^\nu \) | \( q^\alpha q^\beta g^{\mu \nu} \) | \( g^{\alpha \beta} g^{\mu \nu} \) |
|\( p^\mu p^\nu g^{\alpha \beta} \) | \( p^\mu p^\nu g^{\alpha \mu} \) | \( p^\mu p^\nu q^\alpha g^\beta \) | \( p^\mu p^\nu q^\alpha g^\mu \) | \( p^\mu p^\nu g^{\alpha \mu} \) | \( g^{\alpha \beta} g^{\mu \nu} \) |
|\( p^\mu q^\nu g^{\alpha \beta} \) | \( p^\mu q^\nu g^{\alpha \mu} \) | \( p^\mu q^\nu q^\alpha g^\beta \) | \( p^\mu q^\nu q^\alpha g^\mu \) | \( p^\mu q^\nu g^{\alpha \mu} \) | \( g^{\alpha \beta} g^{\mu \nu} \) |
|\( q^\mu p^\nu g^{\alpha \beta} \) | \( q^\mu p^\nu g^{\alpha \mu} \) | \( q^\mu p^\nu q^\alpha g^\beta \) | \( q^\mu p^\nu q^\alpha g^\mu \) | \( q^\mu p^\nu g^{\alpha \mu} \) | \( g^{\alpha \beta} g^{\mu \nu} \) |
|\( q^\mu q^\nu g^{\alpha \beta} \) | \( q^\mu q^\nu g^{\alpha \mu} \) | \( q^\mu q^\nu q^\alpha g^\beta \) | \( q^\mu q^\nu q^\alpha g^\mu \) | \( q^\mu q^\nu g^{\alpha \mu} \) | \( g^{\alpha \beta} g^{\mu \nu} \) |
generates two sets of 14 independent tensor structures following our choice the result is

\[
\begin{align*}
A_5 &= A_6, & A_8 &= A_9, & A_{10} &= A_{11}, \\
A_{13} &= A_{14}, & A_{18} &= A_{19}, & A_{21} &= A_{22}, \\
A_{24} &= A_{28}, & A_{25} &= A_{29}, & A_{26} &= A_{30}, \\
A_{27} &= A_{31}, & A_{32} &= A_{36}, & A_{34} &= A_{37}, \\
A_{33} &= A_{38}, & A_{35} &= A_{39},
\end{align*}
\]

where all \( A_i \) are thought as functions of the invariants \( k^2, p^2, q^2 \). After substituting (45) into \( \Gamma^{\mu \nu \alpha \beta}(p, q) \) the 43 invariant tensors of the decomposition are multiplied by only 29 invariant amplitudes. Condition (b), which is vector current conservation on the two vertices with indices \( \alpha \) and \( \beta \), allows to reexpress some divergent \( A_i \) in terms of other finite ones. The constraint

\[
p_a \Gamma^{\mu \nu \alpha \beta}(p, q) = q_\beta \Gamma^{\mu \nu \alpha \beta}(p, q) = 0
\]

generates two sets of 14 independent tensor structures each, so that in order to fulfill (46) each coefficient is separately set to vanish. The first Ward identity leads to a linear system composed of 10 equations

\[
p_a \Gamma^{\mu \nu \alpha \beta}(p, q) = 0
\]

we choose to solve it for the set \( \{ A_{15}, A_{17}, A_{19}, A_{23}, A_{28}, A_{29}, A_{30}, A_{31}, A_{39}, A_{43} \} \) in which only the first one is convergent and the others are UV divergent. The set cannot contain indeed only divergent amplitudes, since last equation in the system in Eq. (47) involves two \( A_i \), named \( A_{15} \) and \( A_{23} \), which are both convergent. So one of them has to be included in the set. Following our choice the result is

\[
\begin{align*}
A_{15} &= -A_2 \frac{p \cdot q}{p \cdot p}, & A_{17} &= -A_{40} p \cdot p - A_{42} p \cdot q, \\
A_{19} &= -A_{36} p \cdot p - A_{37} p \cdot q, & A_{23} &= -A_{12} p \cdot p - A_{16} p \cdot q.
\end{align*}
\]

In an analogous way we go on with the second Ward identity (WI) after replacing the solution of the previous system in the original amplitude. The new one is indicated by \( \Gamma^{\mu \nu \alpha \beta}_b(p, q) \), where the subscript \( b \) is there to indicate that we have applied condition (b) on \( \Gamma \). The constraint gives

\[
q_\beta \Gamma^{\mu \nu \alpha \beta}_b(p, q) = 0
\]

We solve these equations determining the amplitudes in the set \( \{ A_{1}, A_{20}, A_{22}, A_{36}, A_{38}, A_{40} \} \) in terms of the remaining ones, obtaining

\[
\begin{align*}
A_{38} &= -A_{12} p \cdot p p \cdot q - A_2 p \cdot q q \cdot q, \\
A_{40} &= -A_{41} q \cdot q, \\
A_{1} &= -A_3 q \cdot q, & A_{20} &= -A_4 p \cdot q - A_7 q \cdot q, \\
A_{22} &= -A_{37} - A_{11} p \cdot q - A_{14} q \cdot q, \\
A_{36} &= -A_6 p \cdot q - A_9 q \cdot q.
\end{align*}
\]

The manipulations above have allowed a reduction of the number of invariant amplitudes from the initial 43 to 13 using the \( \{ \mu, \nu \} \) symmetry (14 equations), the first WI on \( p_a \) (10 equations) and the second WI on \( q_\beta \) (6 equations). The surviving invariant amplitudes in which the amplitude \( \Gamma^{\mu \nu \alpha \beta}_c(p, q) \) can be expanded using the form factors are \( \{ A_2, A_3, A_4, A_6, A_7, A_9, A_{11}, A_{12}, A_{14}, A_{16}, A_{37}, A_{41}, A_{42} \} \). This set still contains 3 divergent amplitudes, \( \{ A_{37}, A_{41}, A_{42} \} \). The amplitude \( \Gamma^{\mu \nu \alpha \beta}_c(p, q) \) is indeed ill-defined until we impose on it condition (c) written in Eq. (42) which results in the following system

\[
A_{28} = \frac{1}{2}[-A_{20} - A_1 p \cdot p - A_4 p \cdot q],
\]

\[
A_{29} = A_{22} - A_6 p \cdot p - A_{11} p \cdot q,
\]

\[
A_{30} = -\frac{1}{2}[A_3 p \cdot p + A_7 p \cdot q],
\]

\[
A_{31} = -A_9 p \cdot p - A_{14} p \cdot q,
\]

\[
A_{39} = -A_{38} \frac{p \cdot p}{p \cdot q},
\]

\[
A_{43} = -A_{41} \frac{p \cdot p}{p \cdot q}.
\]
\[- A_3 [1 + \frac{p \cdot p}{2p \cdot q}] + A_6 + \frac{1}{2} A_7 - A_9 - \frac{A_{41}}{p \cdot q} = 0, \]  

\[A_{37} + A_{42} + A_4 [p \cdot p + p \cdot q] + A_{11} p \cdot q + \frac{1}{2} A_7 q \cdot q + A_{11} q \cdot q + \frac{1}{2} A_3 \frac{p \cdot pq \cdot q}{p \cdot q} = 0, \]  

\[
\frac{1}{2} A_2 \frac{p \cdot pq \cdot q}{p \cdot p} - A_{41} \frac{p \cdot p + q \cdot q}{p \cdot q} - \frac{1}{2} A_3 p \cdot p + A_7 (p \cdot p + \frac{1}{2} p \cdot q) + A_6 p \cdot q \\
+ A_{12} \frac{1}{2} (p \cdot q + q \cdot q) + A_{14} (p \cdot q + 2q \cdot q) + 2A_{37} - \Pi(p^2) - \Pi(q^2) = 0. \]  

The system can be solved for \(A_{37}, A_{41}\) and \(A_{42}\)

\[
A_{37} = -\frac{A_2}{4} \frac{p \cdot pq \cdot q}{p \cdot p} + \frac{1}{4} A_3 p \cdot p - \frac{1}{4} A_7 (2p \cdot p + p \cdot q) \\
+ \frac{1}{2} A_{41} \frac{p \cdot p + q \cdot q}{p \cdot q} - \frac{1}{2} A_6 p \cdot q \\
- \frac{1}{4} A_{12} (p \cdot q + 2q \cdot q) - \frac{1}{2} A_{14} (p \cdot q + 2q \cdot q) \\
+ \frac{1}{2} [\Pi(p^2) + \Pi(q^2)] 
\]

\[
A_{41} = \frac{A_2}{2} p \cdot p - (A_3 - A_6 - A_9) p \cdot q 
\]

\[
A_{42} = \frac{A_2}{2} p \cdot p \left( \frac{p \cdot p}{p \cdot q} + 1 - \frac{q \cdot q}{p \cdot q} \right) \\
+ \frac{1}{2} A_7 (p \cdot p + p \cdot q - q \cdot q) - A_4 (p \cdot p + p \cdot q) \\
- (A_6 - A_9) p \cdot p + (A_{11} - A_{13}) (q \cdot q + p \cdot q). 
\]

After these steps we end up with an expression for \(\Gamma\) written in terms of only 10 invariant amplitudes, that are \(X = \{A_2, A_3, A_6, A_7, A_9, A_{14}, A_{15}, A_{16}\}\), significantly reduced respect to the original 43. Further reductions are possible (down to 8 independent invariant amplitudes), however, since these reductions just add to the complexity of the related tensor structures, it is convenient to select an appropriate set of reducible (but finite) components characterized by a simpler tensor structure and present the result in that form. The 13 amplitudes introduced in the final decomposition are, in this respect, a good choice since the corresponding tensor structures are rather simple. These tensors are combinations of the 43 monomials listed in Table I.

The set \(X\) is very useful for the actual computation of the tensor integrals and for the study of their reduction to scalar form. To compare with the previous study of Giannotti and Mottola [16] we have mapped the computation of the components of the set \(X\) into their structures \(F_i\) (\(i = 1, 2, \ldots, 13\)). Also in this case, the truly independent amplitudes are 8. One can extract, out of the 13 reducible amplitudes, a consistent subset of 8 invariant amplitudes. The remaining amplitudes in the 13 tensor structures are, in principle, obtainable from this subset.

### B. Reorganization of the amplitude

Before obtaining the mapping between the amplitudes in \(X\) and the structures \(F_i\), we briefly describe the tensor decomposition introduced in [16] which defines these 13 structures. We define the rank-2 tensors

\[
u^{\alpha \beta}(p, q) = (p \cdot q)g^{\alpha \beta} - q^\alpha p^\beta, \]

\[
w^{\alpha \beta}(p, q) = p^2 q^2 g^{\alpha \beta} + (p \cdot q) p^\alpha q^\beta - q^2 p^\alpha p^\beta \\
- p^2 q^2 q^\alpha q^\beta, \]

which are Bose symmetric,

\[w^{\alpha \beta}(p, q) = w^{\beta \alpha}(q, p), \]

and conserve vector current,

\[p_{\alpha} u^{\alpha \beta}(p, q) = q_{\beta} u^{\alpha \beta}(p, q) = 0, \]

\[p_{\alpha} w^{\alpha \beta}(p, q) = q_{\beta} w^{\alpha \beta}(p, q) = 0. \]

These two tensors are used to build the set of 13 tensors catalogued in Table II. They are linearly independent for generic \(k^2\), \(p^2\), \(q^2\) different from zero. Five of the 13 tensors are Bose symmetric, namely,

\[i_{\mu \alpha \beta}^{\mu}(p, q) = i_{\mu \alpha \beta}^{\nu}(q, p), \quad i = 1, 2, 7, 8, 13, \]

while the remaining eight tensors form four pairs which are overall related by Bose symmetry

\[i_{\mu \alpha \beta}^{\nu}(p, q) = i_{\mu \alpha \beta}^{\nu}(q, p), \]

\[i_{\mu \alpha \beta}^{\nu}(p, q) = i_{\mu \alpha \beta}^{\nu}(q, p), \]

\[i_{\mu \alpha \beta}^{\nu}(p, q) = i_{\mu \alpha \beta}^{\nu}(q, p). \]
The amplitude in (34) can be expanded in this basis composed as

$$\Gamma^{\alpha\nu\rho\beta}(p,q) = \sum_{i=1}^{13} F_i(s; s_1, s_2, m^2) T_i^{\alpha\nu\rho\beta}(p,q),$$  

(74)

where the invariant amplitudes $F_i$ are functions of the kinematical invariants $s = k^2 = (p + q)^2$, $s_1 = p^2$, $s_2 = q^2$ and of the internal mass $m$. In [16] the authors use the Feynman parametrization and momentum shifts in order to identify the expressions of these amplitudes in terms of parametric integrals, which was the approach followed also by Rosenberg in his original identification of the 6 invariant amplitudes of the AVV anomaly diagram. If we choose to reorganize all the mononials into the simpler set of 13 tensor groups shown in Table II, then we need to map the $A_i$ included in the $\chi$ set into the $F_i$ ($i = 1, \ldots, 13$). The mapping is given by

$$F_1 = \frac{1}{3k^2} \left[ A_4(4p \cdot q + 3p \cdot p) + 2A_{11}(p \cdot q + 2q \cdot q) + 2A_6p \cdot p + 2A_7q \cdot q - 2A_{14}q \cdot q - A_{16}q \cdot q + 2A_3 \frac{p \cdot q \cdot q \cdot q}{p \cdot q} \right],$$  

(75)

$$F_2 = \frac{1}{3k^2} \left[ -2A_3 \left( \frac{p \cdot p}{p \cdot q} + 2 \right) + 4A_6 + A_7 - 2A_9 - A_{12} \right],$$  

(76)

$$F_3 = \frac{1}{12k^2} \left[ A_4(2p \cdot q + 3q \cdot q) - 2A_{11}(p \cdot q + 2q \cdot q) - 2A_6p \cdot p - 2A_7q \cdot q + 2A_{14}q \cdot q + A_{16}q \cdot q - 2A_3 \frac{p \cdot p \cdot q \cdot q}{p \cdot q} \right],$$  

(77)

Table II. Basis of 13 fourth rank tensors satisfying the vector current conservation on the external lines with momenta $p$ and $q$.

12 & (p \cdot q\delta^{\mu\nu} - q^2p^\alpha) \left[ 2p^\beta p^\mu p^\nu - p^2g^\alpha p^\mu + g^\beta p^\nu \right] \\
13 & (p^3q^\mu + p^3q^\nu)g^{\alpha\beta} + p \cdot q(q^\alpha g^{\beta\mu} + g^\alpha g^{\beta\nu}) - g^{\mu\nu}u^{\alpha\beta} - (g^{\beta\nu}p^\alpha + g^{\alpha\mu}p^\nu)q^\alpha - (g^{\alpha\nu}q^\mu + g^{\alpha\mu}q^\nu)p^\beta \\
\hline
\end{array}
$$

(78)
\[ F_{11} = \frac{A_{12}}{2q \cdot p} - A_2 \frac{2p \cdot p}{2p \cdot p}, \quad (85) \]
\[ F_{12} = \frac{A_1}{2p \cdot q} + \frac{A_7}{2p \cdot p}, \quad (86) \]
\[ F_{13} = \frac{1}{2} A_6 (p \cdot p + p \cdot q - q \cdot q) + \frac{1}{4} A_5 (p \cdot p + p \cdot q - q \cdot q) + \frac{A_2 p \cdot q q \cdot q}{4p \cdot p} + \frac{A_7 (p \cdot p + 2q \cdot q)}{4p \cdot q} + \frac{1}{2} A_9 \left[ q \cdot p + p \cdot \frac{2q \cdot q + 1}{p \cdot q}\right] - \frac{1}{2} \Pi(p) + \Pi(q), \quad (87) \]

We have shown how to obtain the 13 \( F_i \)'s, starting from our derivation of the one-loop full amplitude \( \Gamma^{\mu \nu \alpha \beta}(p, q) \) leading to the ten invariant amplitudes of the set \( \mathcal{X} \). Since we know the analytical expression of the \( A_i \) involved, we can go one step further and give all the \( F_i \)'s in their analytical form in the most general kinematic configuration.

**IV. TRACE CONDITION IN THE NONCONFORMAL CASE**

Similarly to the chiral case, we can fix the correlator by requiring the validity of a trace condition on the amplitude, besides the two Ward identities on the conserved vector

\[ g_{\mu \rho} \Gamma^{\mu \nu \alpha \beta}(p, q) = \Lambda^{\alpha \beta}(p, q) - \frac{e^2}{6 \pi^2} u^{\alpha \beta}(p, q). \quad (88) \]

We comment below on this equation, in relation to the scales present in the perturbative expansion of the correlator, which are, besides the fermion mass \( m \), the energy at which we probe the correlator \( (s) \) and the subtraction point after renormalization \((\mu \text{ or } M)\). We have also defined

\[ \Lambda^{\alpha \beta}(p, q) = -m(i\epsilon + p \cdot s + i\epsilon q \cdot s + s \cdot s) \gamma^\alpha (s \cdot J^\beta(s)). \quad (89) \]

A direct computation gives

\[ \Lambda^{\alpha \beta}(p, q) = G_1(s, s_1, s_2, m^2) u^{\alpha \beta}(p, q) + G_2(s, s_1, s_2, m^2) w^{\alpha \beta}(p, q). \quad (90) \]

with

\[ 3sF_1(s, s_1, s_2, m^2) = G_1(s, s_1, s_2, m^2) - \frac{e^2}{6 \pi^2} \quad (91) \]

\[ 3sF_2(s, s_1, s_2, m^2) = G_2(s, s_1, s_2, m^2) \quad (92) \]

and

\[ G_1(s, s_1, s_2, m^2) = \frac{e^2 \gamma m^2}{\pi^2 \sigma} + \frac{e^2 D_2(s, s_2, m^2)s_3 m^2}{\pi^2 \sigma^2} \left[ s^2 + 4s_1s - 2s_2s - 5s_1^2 + s_1^2 + 4s_1s_2 \right] \]
\[ - \frac{e^2 D_1(s, s_1, m^2)s_1 m^2}{\pi^2 \sigma^2} \left[ 12(s - s_1)^2 + 2s_1^2 + 4s_1s_2 \right] - \frac{2m^2 \gamma}{\pi^2 \sigma} \left[ (s - s_1)^3 - s_1^2 + (3s + 3s_1)s_2^2 + (-3s^2 - 10s_1s + s_1^2)s_2 \right] \]
\[ \times \frac{m^2 \gamma}{\pi^2 \sigma} \left[ (s - s_1)^3 - s_1^2 + (3s + 3s_1)s_2^2 + (-3s^2 - 10s_1s + s_1^2)s_2 \right] - \frac{2m^2 \gamma}{\pi^2 \sigma}. \quad (93) \]

\[ G_2(s, s_1, s_2, m^2) = -\frac{2e^2 m^2}{\pi^2 \sigma} - \frac{2e^2 D_2(s_1, s_2, m^2)s_1 m^2}{\pi^2 \sigma^2} \left[ s_1^2 + 2s_1s_2 + 4s_1s_2 + 2s_2^2 + s_1^2 + 4s_1s_2 \right] \]
\[ - \frac{2e^2 D_1(s_1, s_1, m^2)s_1 m^2}{\pi^2 \sigma^2} \left[ 3s_1^2 - 2s_1^2 - 2s_1^2 + 2s_1^2 + s_1^2 + 4s_1s_2 \right] - \frac{2m^2 \gamma}{\pi^2 \sigma} \left[ (s_1 - s_1)^3 - s_1^2 + (3s + 3s_1)s_2^2 + (-3s^2 - 10s_1s + s_1^2)s_2 \right] \]
\[ \times \frac{4m^4}{\pi^2 \sigma} + \frac{m^2 \gamma}{\pi^2 \sigma} \left[ s_1^3 - (s_1 + s_2)s_2^2 - (s_1^2 - 6s_2s_1 + s_1^2)s_2 + (s_1 - s_2^2)(s_1 + s_2) \right]. \quad (94) \]

where \( \gamma = s - s_1 - s_2, \quad \sigma = s^2 - 2(s_1 + s_2)s + (s_1 - s_2)^2 \) and the scalar integrals \( D_1(s_1, s_1, m^2), \quad D_2(s_1, s_1, m^2), \quad C_1(s_1, s_1, s_2, m^2) \) for generic virtualities and masses are defined in Appendix A. We have checked that the final expressions of the form factors in the most general case, obtained either by imposing the trace condition on the whole amplitude in Eq. (88) or the Ward identity in the form given by Eq. (42) exactly coincide. In Appendix B we discuss this equivalence in the simpler case of a massless fermion in the loop.
V. THE OFF-SHELL MASSIVE $\langle T J J \rangle$
CORRELATOR

To obtain the explicit expression of the parametric integrals which describe the form factors, we follow an approach similar to that of [20], for the case of the chiral gauge anomaly. These have been obtained by recomputing the anomaly diagrams by dimensional reduction together with the tensor-to-scalar decomposition of the Feynman amplitudes. For instance, in [20] we have given the explicit expressions of the parametric integrals of Rosenberg using this trick. The correctness of the result can be checked numerically by comparing the parametric forms to the explicit computation. In this case the procedure is identical, though the computations are very involved. By comparing the two approaches we extract, indirectly, an explicit expression of the parametric forms of these integrals, introduced in [16]. We have checked that indeed there is perfect numerical agreement between our computation and the parametric result, as discussed in Appendix C.

We introduce in this section the main results of our computation which will be used in the next sections for further analysis. The complete expressions of the form factors $F_i$ ($i = 1, \ldots, 13$) in the massive and then in the massless case are contained in Appendix D and E respectively, whereas the master integrals are collected in Appendix A. In both cases the virtualities of the external lines are generic and denoted by $s_1, s_2$. After presenting the complete expressions, we discuss several kinematical limits of the result, in particular, the on-shell limit for the two vector lines ($s_1 \to 0, s_2 \to 0$) in order to better understand the structure of the whole correlator. The appearance of generalized anomaly poles in the correlator and their IR decoupling under the most general conditions will be discussed thoroughly.

Notice that $F_{13}$ contains two vacuum polarization diagrams with the two photon momenta which are divergent and we are bound to define a suitable renormalization of the 2-point function which will affect the running of the coupling. In the next section we will address the explicit relation between renormalization schemes and running of the coupling in the context of the renormalization of the correlator.

A. Anomaly poles and their UV/IR significance

There are close similarities between the effective action in the case of the chiral gauge anomaly and the conformal case, due to the presence of massless poles. In [20] we have analyzed the fact that in the chiral case the anomaly is entirely generated by the longitudinal component $w_L$, which is indeed isolated for any configuration of the photon momenta. This is somehow unexpected since the dispersive analysis shows that the pole in $w_L$ is coupled only under a specific kinematic condition, and is usually interpreted as an infrared effect. Nevertheless there is a complete equivalence between the representation of the anomaly diagram in the Rosenberg representation—where the pole is not extracted as an independent component—and the L/T representation in which the pole is isolated under any kinematical configuration (and even in the massive case). This is apparent from the broken anomalous Ward identities satisfied by the AVV diagram where the mass corrections and the anomaly term can be separately identified [20].

To illustrate the emergence of a similar behavior in the case of the conformal anomaly, it is sufficient to notice in the expression of the massive $F_1$ given in Eq. (D1) the presence of the isolated contribution ($F_{1\text{pole}} = -e^2 / (18 \pi^2 s)$) which only accounts for the massless $F_1$ in Eq. (E1). This component, indeed, is responsible for the trace anomaly also in the massive case, even though there appear extra corrections with mass-dependent terms. Obviously also in this case, which is generic from the kinematical point of view, one can clearly show that the pole does not couple in the infrared if we compute the residue of the entire amplitude. The anomaly pole, in fact, appears in the spectral function only in a special kinematic configuration, i.e., when the fermion-antifermion pair of the anomaly diagram is collinear. However both in the case of the AVV diagram and in the conformal case, as evident from the expression of $F_1$, it reappears as an extra contribution and is responsible for the trace anomaly. It is rather easy to show the pole dominance of the anomaly away from the conformal point (massive case) at high energy, since the non anomalous terms present in $F_1$ and $F_2$ are subleading at large $s$. We are entitled to separate the pole contribution, which describes the nonlocal contribution to the trace anomaly, from the rest, and rewrite the $F_1$ form factor and effective action, respectively, as

$$F_1 = F_{1\text{pole}} + \tilde{F}_1$$

and

$$S = S_{\text{pole}} + \tilde{S}.$$  (96)

The reminder ($\tilde{S}$) includes all the remaining contributions coming from the several form factors of the expansion, while the pole part gives

$$S_{\text{pole}} = -\frac{e^2}{36 \pi^2} \int d^4 x d^4 y (\Box h(x)$$

$$- \partial_\mu \partial_\nu h_{\mu \nu}(x) \Box^{-1} F_{\alpha \beta}(x) F^{\alpha \beta}(y).$$  (97)

As we have just mentioned, it is not difficult to show that the anomaly pole in $F_1$, in the general kinematical case (e.g., for off-shell photons and a massive fermion in the loop) decouples in the infrared (i.e., its residue vanishes) while it remains coupled in the massless on-shell limit. In other configurations (for any of the two photons off-shell) it is also decoupled. This behavior is in perfect analogy with the chiral case [20].
B. Massive and massless contributions to anomalous Ward identities and the trace anomaly

Anomalous effects are associated with massless fermions, and for this reason, when we analyze the contribution to the anomaly for a massive correlator, we need to justify the distinction between massless and massive contributions. The latter contribute to the anomalous Ward identity, in our approach, via terms of $O(m^2/s^2)$, where $s = k^2$ is the virtuality of the graviton vertex. At nonzero momentum transfer ($k \neq 0$) the second term on the right-hand side of Eq. (88) is interpreted as an anomalous contribution, proportional to an asymptotic $β$ function ($β_{as}$) of the theory, coming from the residue of the anomaly pole which appears in the form factor $F_1$. While the appearance of the asymptotic $β$ function of the theory (which coincides with the $β$ function of the $\overline{MS}$ scheme) is expected at large $s$, where all the remaining scales of the theory ($s_1, s_2, m$) can be dropped, corrections to the asymptotic description in the ultraviolet (UV) are expected. At the same time, in the far infrared (IR) region, below the fermion mass, the anomalous contribution should approach zero in a certain fashion, which will be specified below.

A complete quantitative understanding of this point for a general kinematics (e.g. for $s \neq 0$) remains, in a way, an open issue, but much more can be said for the simpler case of zero momentum transfer, where a consistent pattern of separation between massless and massive contributions to the correlator emerge in the UV region. In this case the virtuality of the two photons and the fermion mass $m$ (plus a renormalization scale $\mu$ or $M$) are the scales which appear in the renormalized perturbative expansion. Related analysis have been presented in [16,27] and our conclusions do not differ from these previous investigations. We summarize the main points.

Respect to the case of the chiral anomaly, the trace anomaly is connected with the regularization procedure involved in the computation of the diagrams. In our analysis we have used dimensional regularization (DR) and we have imposed conservation of the vector currents, the symmetry requirements on the correlator and the conservation of the energy-momentum tensor. As we move from 4 to $d$ spacetime dimensions (before that we renormalize the theory), the anomaly pole term appears quite naturally in the expression of the correlator. This is not surprising, since QED in $d \neq 4$ dimensions is not even classically conformal invariant and the trace of the energy-momentum tensor in the classical theory involves both a $F^2$ term ($\sim (d - 4)F^2$) beside, for a massive correlator, a $\bar{\psi}\psi$ contribution. Let us summarize the basic features concerning the renormalization property of the correlator as they emerge from our direct computation.

1) The anomalous Ward identity obtained by tracing the correlator ($\Gamma^{\mu\nu\alpha\beta}$) with $g_{\mu\nu}$ involves only the $F_1$ and $F_2$ form factors in the massive case; in the massless case the scale breaking appears uniquely due to $F_1$ via the term $e^3/(12\pi^2)u^{a\beta}(p, q)$, as pointed out before. The finiteness of the two form factors involved in the trace of the correlator is indeed evident. 2) The residue of the pole term $(e^3/(12\pi^2))$ in $F_1$ is affected by the renormalization of the entire correlator (the form factor $F_{13}$ is the only one requiring renormalization) only by the redefinition of the bare coupling ($e^2$) through the renormalization factor $Z_3$. At this point, the exponentiation of the residue at the pole as a contribution proportional to the $β$ function of the theory is, in a way, ambiguous [28], since the $β$ function is related to a given renormalization scheme. We stress once more that Eq. (88) does not involve a renormalization scheme—which at this point has not yet been defined—but just a regularization. We have regulated the infinities of the theory but we have not specified a subtraction of the infinities. For this reason, the substitution

$$(e^3/(12\pi^2)) \rightarrow 2β_{as}(e)/e$$

which attributes the mass-independent term in $F_1$ to a specific $β$ function, the asymptotic one ($β_{as}$), as we are going to elaborate below, requires some clarification.

To fully appreciate this point, it is convenient to go back to the unrenormalized Ward identity (42) and differentiate it with respect to the momentum $q$ and then set $p = -q$ ($k = 0$) by going to zero momentum transfer. One obtains the derivative Ward identity

$$g_{\mu\nu}(\gamma^\rho\rho\beta)(p, -p) = 2p^2 d\Pi/dp^2(p^2g^{a\beta} - p^a p^\beta).$$

The appearance of the derivative of the scalar self-energy of the photon on the right-hand side of the previous equation is particularly illuminating, since it allows to relate this expression to a particular $β$ function of the theory, which is not the asymptotic $β_{as}$ considered in Eq. (98). This $β$ function is useful for describing the IR running of the coupling.

To illustrate this point we start from the expression of the scalar amplitude appearing in the photon self-energy in DR

$$\Pi(p^2, m) = \frac{e^2}{2\pi^2} \left( \frac{1}{6e} - \frac{1}{6} \int_0^1 dx x(1 - x) \right) \times \log \frac{m^2 - p^2x(1 - x)}{4\pi\mu^2}$$

whose renormalization at zero momentum gives

$$\Pi_R(p^2, m) = \Pi(p^2, m) - \Pi(0, m) = - \frac{e^2}{2\pi^2} \int_0^1 x(1 - x) \log \frac{m^2 - p^2x(1 - x)}{m^2}. $$

085001-11
Using this expression, we can easily compute
\[
2p^2 \frac{d \Pi}{d p^2} = 2p^2 \frac{d \Pi_R}{d p^2} = -\frac{e^2}{6\pi^2} + \frac{e^2 m^2}{\pi^2} \int_0^1 dx \frac{x(1-x)}{m^2 - p^2 x(1-x)}.
\]

(102)

Notice that this result does not depend on the renormalization scheme due to the presence of the derivative respect to \(p^2\). Notice also that the \(\beta\) function of the theory evaluated in the zero momentum subtraction scheme is exactly given by the right-hand side of the previous expression
\[
2p^2 \frac{d \Pi_R}{d p^2} = -\frac{\beta(e, p^2)}{e^2},
\]

(103)

(where \(\beta(e, p^2) = 2e\beta(e, p^2)\)), but this result does not hold, generically, in any scheme. The identification of anomalous (massless) effects in the theory, as exemplified by these simpler Ward identity, should then be obtained by extracting the appropriate \(\beta\) function of the theory, whose running should be driven by the effective massless degrees of freedoms (fermions, in our case) at the relevant observation scale \(p^2\).

Clearly, in the case of Eq. (103) all the mass contributions have been absorbed into the very definition of the \(\beta\) function. Notice that if \(p^2 \ll m^2\) this \(\beta\) function, after a rearrangement gives
\[
\frac{-\beta(e^2, p^2)}{e^2} = \frac{e^2}{\pi^2} \int_0^1 dx \frac{p^2 x^2(1-x)^2}{m^2 - p^2 x(1-x)}
\]

(104)

and therefore it vanishes as \(\beta \sim O(p^2/m^2)\) for \(p^2 \to 0\). Equivalently, by taking the \(m \to \infty\) limit we recover the expected decoupling of the fermion (due to a vanishing \(\beta\)) since we are probing the correlator at a scale \((p^2)\) which is not sufficient to resolve the contribution of the fermion loop. On the contrary, as \(p^2 \to \infty\), with \(m\) fixed, the running of the \(\beta\) function is the usual asymptotic one \(\beta_{as}(e^2) \sim e^4/(6\pi^2)\) modified by corrections \(O(m^2/p^2)\). The UV limit is characterized by the same running typical of the massless case, as expected.

Notice that the right-hand side of Eq. (99), as we have already remarked, does not depend on the renormalization scheme, while the \(\beta\) function does and Eq. (103) should be understood as a definition. For this reason, \(\beta(e^2, p^2)\) correctly describes the IR running of the coupling as \(p^2 \ll m^2\), and in this case it is obvious that massless anomalous effects of scale breaking are not present in this specific limit.

In the case of regularization scheme different from zero momentum subtraction, there are some differences which should be taken into consideration. For instance, in a mass-dependent scheme one subtracts the value of the graph at a Euclidean momentum point \(p^2 = -M^2\), redefining the scalar self-energy as

\[
\Pi^R(p^2, m, M) = \Pi(p^2, m) - \Pi(p^2 = -M^2, m)
\]

\[
= \frac{e^3}{2\pi^2} \left[ \int_0^1 dx x(1-x) \log \frac{m^2 - p^2 x(1-x)}{m^2 + M^2 x(1-x)} \right]
\]

(105)

which gives, respect to the previous \((M=0)\) scheme, a \(\beta\) function now of the form
\[
\beta(e) = -\frac{e}{2M} \frac{d}{dM} \frac{e^2}{2\pi^2} \int_0^1 dx x(1-x) \log \frac{m^2 - p^2 x(1-x)}{m^2 + M^2 x(1-x)}
\]

\[
= \frac{e^3}{2\pi^2} \int_0^1 dx x(1-x) \frac{M^2 x(1-x)}{m^2 + M^2 x(1-x)}.
\]

(106)

For large values of \(M\), this \(\beta\) function describes the usual UV running since
\[
\beta(e) \sim \frac{e^3}{2\pi^2} \int_0^1 dx x(1-x) = \beta(e)_\text{ir} = \frac{e^3}{12\pi^2}.
\]

(107)

In this second scheme (the regularization independent) right-hand side of Eq. (99) can be interpreted as due to an anomalous contribution coming from the pole plus some explicit mass corrections, as obvious from the first and second term of (102). We conclude with some considerations on a third (mass-independent) scheme.

In the \(\overline{MS}\) scheme, the renormalization of the photon self-energy is performed via the subtraction
\[
\Pi_R(p^2, m, \mu) = \Pi(p^2, m, \mu) - \frac{e^2}{12\pi^2} \left[ \frac{1}{\epsilon} + \gamma - \log 4\pi \right]
\]

(108)

which gives directly an asymptotic \(\beta\) function since
\[
\beta(e) = \frac{e}{2\mu} \frac{d}{d\mu} \Pi_R(p^2, m, \mu)
\]

\[
= \frac{e^3}{2\pi^2} \int_0^1 dx x(1-x) = \frac{e^3}{12\pi^2}.
\]

(109)

It is clear, from these considerations, that a judicious definition of the \(\beta\) function allows a correct interpretation of the right-hand side of (96) and (99). In the \(\overline{MS}\) scheme, the breaking of scale invariance can be attributed to a UV running of the coupling (for \(p^2 \gg m^2\)) plus mass corrections which are suppressed as \(O(m^2/p^2)\). Notice that in this case the renormalization scale \((\mu)\) should be \(O(p^2)\), since we should not allow large logarithms to be present in the perturbative expansion. In this sense, the extrapolation of the \(\overline{MS}\) result to \(p^2 \sim \mu^2 \ll m^2\) should be forbidden by the same criterion, since large logs of the relevant scales \((\log(m/\mu))\) would otherwise be generated. In the far infrared region \(p^2 \ll m^2\) the use of the same \(\beta\) function is indeed not appropriate, since the same scheme does not
correctly describe the decoupling of the anomaly, which instead should occur, since there is no massless fermion in the theory.

To conclude this discussion we just mention that the \(MS\) scheme can be used, obviously, both to describe the far IR and the far UV regions of the theory, with the condition that we are bound to choose a vanishing \(\beta\) function at \(p^2 \ll m^2\) and an asymptotic one for \(p^2 \gg m^2\) and assuring continuity of the gauge coupling across the fermion mass scale though the \(\beta\)-function is discontinuous. This is the standard procedure followed in the \(\overline{MS}\) scheme as, for instance, in QCD factorization, improved with the inclusion of threshold effects at the crossing scales (see for instance \([29,30]\)) where the number of massless flavors change.

C. The off-shell massless \((TJJ)\) correlator

Clearly, as we perform the massless limit on the amplitude, the residue of the same anomaly pole—identified above in the contribution \(F_{\text{pole}}\)—is still present, but will now be decoupled in the infrared.

In the massless case the scalar functions \(F_i\) depend only on the kinematic invariants \(s, s_1, s_2\) but we still retain the last entry of these functions and set it equal to 0 for clarity, using the notation \(F_i = F_i(s; s_1, s_2, 0)\). These new functions are computed starting from the massive ones and letting \(m \to 0\) and \(\mathcal{A}_0(m^2) \to 0\), i.e., eliminating all the massless tadpoles generated in the zero fermion mass limit.

The off-shell massless invariant amplitudes \(F_i(s; s_1, s_2, 0)\) are here given in terms of a new set of master integrals listed in Appendix A. We give here only the simplest invariant amplitudes, leaving the remaining ones to the Appendix E. The anomaly pole is clearly present in \(F_1\), which is given by

\[ F_1(s; s_1, s_2, 0) = -\frac{e^2}{18\pi^2 s}, \]  

while

\[ F_2(s; s_1, s_2, 0) = 0. \]  

The complete \((TJJ)\) correlator is very complicated in this case as the long expressions of the form factors show, but a deeper analysis of its poles by computing the residue in \(s = 0\) can be useful to draw some conclusions. The single pieces of \(\Gamma^{\mu\nu\rho\beta}(s; s_1, s_2, 0)\) indeed contribute as

\[
\begin{align*}
\lim_{s \to 0} F_1(s; s_1, s_2, 0) t_i^{\mu\nu\rho\beta} & = -\frac{e^2}{18\pi^2} t_i^{\mu\nu\rho\beta} \bigg|_{s \to 0}, \\
\lim_{s \to 0} F_3(s; s_1, s_2, 0) t_3^{\mu\nu\rho\beta} & = \frac{e^2}{72\pi^2} t_3^{\mu\nu\rho\beta} \bigg|_{s \to 0}, \\
\lim_{s \to 0} F_5(s; s_1, s_2, 0) t_5^{\mu\nu\rho\beta} & = \frac{e^2}{72\pi^2} t_5^{\mu\nu\rho\beta} \bigg|_{s \to 0}, \\
\lim_{s \to 0} F_7(s; s_1, s_2, 0) t_7^{\mu\nu\rho\beta} & = \frac{e^2}{36\pi^2} t_7^{\mu\nu\rho\beta} \bigg|_{s \to 0}.
\end{align*}
\]

while \(F_2\) is absent in the massless case. The residues of the \(F_i(s; s_1, s_2, 0)\) not included in the equation above are all vanishing. Combining the results given above one can easily check that the entire correlator is completely free from anomaly poles as

\[
\lim_{s \to 0} \Gamma^{\mu\nu\rho\beta}(s; s_1, s_2, 0) = 0
\]

D. The on-shell massive \((TJJ)\) correlator

A particular case of the \((TJJ)\) correlator is represented by its on-shell version with a massive fermion in the loop. If we contract \(u^{\alpha\beta}(p, q)\) and \(w^{\alpha\beta}(p, q)\) with the polarization tensors \(\epsilon_\alpha(p)\) and \(\epsilon_\beta(q)\) requiring \(\epsilon_\alpha(p)p^\alpha = 0, \epsilon_\beta(p)p^\beta = 0\), the first tensor \(u^{\alpha\beta}(p, q)\) remains unchanged while \(w^{\alpha\beta}(p, q)\) becomes \(w^{i\alpha\beta}(p, q) = s_1 s_2 g^{i\alpha\beta}\). This will be carefully taken into account when computing the \(s_1 \to 0, s_2 \to 0\) limit of the product of the invariant amplitudes \(F_i\) with their corresponding tensors \(t_i^{\mu\nu\rho\beta}\) \((i = 1, \ldots, 13)\). The invariant amplitudes reported below describe \(F_i(s; 0, 0, m^2)\) whose tensors \(t_i^{\mu\nu\rho\beta}\) are also finite and nonvanishing. They are

\[
\begin{align*}
F_1(s; 0, 0, m^2) & = -\frac{e^2}{18\pi^2 s} + \frac{e^2 m^2}{3\pi^2 s^2} - \frac{e^2 m^2}{3\pi^2 s^2} C_0(s, 0, 0, m^2) \left[ \frac{1}{2} - \frac{m^2}{s} \right], \\
F_3(s; 0, 0, m^2) & = -\frac{e^2}{144\pi^2 s} - \frac{e^2 m^2}{12\pi^2 s^2} - \frac{e^2 m^2}{4\pi^2 s^2} D(s, 0, 0, m^2) - \frac{e^2 m^2}{6\pi^2 s} C_0(s, 0, 0, m^2) \left[ \frac{1}{2} - \frac{m^2}{s} \right], \\
F_5(s; 0, 0, m^2) & = F_3(s; 0, 0, m^2), \\
F_7(s; 0, 0, m^2) & = -4F_3(s; 0, 0, m^2), \\
F_{13R}(s; 0, 0, m^2) & = \frac{11e^2}{144\pi^2} + \frac{e^2 m^2}{4\pi^2 s} + e^2 C_0(s, 0, 0, m^2) \left[ \frac{m^4}{2\pi^2 s^2} + \frac{m^2}{4\pi^2 s} \right] + e^2 D(s, 0, 0, m^2) \left[ \frac{5m^2}{12\pi^2 s} + \frac{1}{12} \right].
\end{align*}
\]
where the on-shell scalar integrals $\mathcal{D}(s, 0, 0, m^2)$ and $C_0(s, 0, 0, m^2)$ are computed in Appendix A; here $F_{13R}$ denotes the renormalized amplitude, obtained by first removing the UV pole present in the photon self-energy by the usual renormalization of the photon wave function and then taking the on-shell limit. The remaining invariant amplitudes $F_i(s, 0, 0, m^2)$ are zero or multiply vanishing tensors in this kinematical configuration so they do not contribute to the correlator. The limit from the massive on-shell form factors to the massless ones is clearer by looking at the series expansion of the scalar integrals around $m = 0$

$$C_0(s, 0, 0, m^2) = \frac{1}{2\pi} \left[ \log \left( -\frac{s}{m^2} \right) \right]^2 - \frac{2m^2}{s^2} \log \left( -\frac{s}{m^2} \right) + O(m^3)$$

(122)

and from this we obtain for $F_1$

$$F_1'(s, 0, 0, m^2) = \frac{e^2 m^2}{\pi s^3} \left[ 1 - \frac{1}{4} \left[ \log \left( -\frac{s}{m^2} \right) \right]^2 \right]$$

(123)

where the notation $F_1'$ denotes the first form factor after the subtraction of the pole in $1/s$.

Using the results given above, the full massive on-shell amplitude is given by

$$\Gamma_{\mu\nu\rho\sigma}(s; 0, 0, m^2) = F_1(s; 0, 0, m^2) \Gamma_{\mu\nu\rho\sigma} + F_2(s; 0, 0, m^2)$$

$$\times (\Gamma_{\mu\nu\rho\sigma} + \Gamma_{\sigma\nu\rho\mu} - 4\Gamma_{\mu\rho\nu\sigma})$$

$$+ F_{13R}(s; 0, 0, m^2)\Gamma_{\mu\nu\rho\sigma},$$

(124)

so that the invariant amplitudes reduce from 13 to 3 and the three linear combinations of the tensors can be taken as a new basis

$$\tilde{t}_1^{\mu\nu\rho\sigma} = \lim_{s_1, s_2 \to 0} t_1^{\mu\nu\rho\sigma} = (sg_{\mu\nu} - k^\mu k^\nu) u^\rho^\sigma(p, q)$$

(125)

$$\tilde{t}_5^{\mu\nu\rho\sigma} + \tilde{t}_7^{\mu\nu\rho\sigma} - 4\tilde{t}_7^{\mu\nu\rho\sigma} = \lim_{s_1, s_2 \to 0} (t_5^{\mu\nu\rho\sigma} + t_7^{\mu\nu\rho\sigma} - 4t_7^{\mu\nu\rho\sigma})$$

$$= -2u^{\mu\nu}(p, q)(s g_{\rho\sigma} + 2(p^\rho p^\sigma)$$

$$+ q^\rho q^\sigma) - 4(p^\mu q^\nu + q^\mu p^\nu)$$

(126)

$$\tilde{t}_{13}^{\mu\nu\rho\sigma} = \lim_{s_1, s_2 \to 0} t_{13}^{\mu\nu\rho\sigma}$$

$$= (p^\mu q^\nu + p^\nu q^\mu) g^{\rho\sigma} + \frac{s}{2} (g_{\mu\nu} g^{\rho\sigma} + g_{\mu\sigma} g^{\rho\nu})$$

$$- g^{\tau\nu}(\frac{s}{2} g_{\rho\sigma} - q^\rho p^\sigma) - (g_{\rho\nu} p^\mu + g_{\rho\sigma} p^\nu) q^\alpha$$

$$- (g_{\rho^\nu} q^\mu + g_{\rho^\sigma} q^\tau) p^\beta,$$

(127)

as previously done in the literature [22]. If we extract the residue of the full amplitude we realize that even though some functions $F_i(s, 0, 0, m^2)$ have kinematical singularities in $1/s$ this polar structure is no longer present in the complete massive correlator

$$\lim_{s \to 0} \Gamma_{\mu\nu\rho\sigma} = 0$$

(128)

showing that in the massive case the $(TJJ)$ correlator exhibits no poles. In a following section we will comment on the interpretation of these massless poles exploiting the analogy with a similar situation encountered in the case of the gauge anomaly.

VI. THE GENERAL EFFECTIVE ACTION AND ITS VARIOUS LIMITS

In this section we present results for the correlator in various kinematical limits. We start from its expression in the on-shell massive case and then perform its expansion in $1/m$ which will be used in a next section to extract the corresponding effective action. As a final step we show the on-shell structure of the invariant amplitudes in the conformal limit.

It is possible to identify from them the structure of the effective action in its most general form. If we denote by $S_i$ the contribution to the effective action due to each form factor $F_i$, then we can write it in the form

$$S_i = \int d^4x d^4y d^4z \delta^4(x-z) \delta^4(y-z)$$

$$\times \int \frac{d^4p}{(2\pi)^8} e^{-ip(x-z)-iq(y-z)} F_i(k, p, q)$$

(129)

where $k = p + q$. We have introduced the operatorial version of the tensor structures $i_{i}^{\mu\nu\rho\sigma}$, denoted by $\tilde{i}_i$, that will be characterized below. Defining

$$\tilde{p}_x^\alpha = i \frac{\partial}{\partial x^\alpha}, \quad \tilde{q}_y^\alpha = i \frac{\partial}{\partial y^\alpha}, \quad \tilde{k}_z^\alpha = -i \frac{\partial}{\partial z^\alpha}$$

(130)

and using the identity

$$\tilde{F}_i(\tilde{k}_z, \tilde{p}_x, \tilde{q}_y) = \delta^4(x-z) \delta^4(y-z)$$

$$\times \delta^4(y-z) \tilde{i}_i^{\mu\nu\rho\sigma}(x, y) h_{\mu\nu} A_\alpha(x) A_\beta(y).$$

(132)

For instance we get

$$\tilde{i}_1^{\mu\nu\rho\sigma}(x, y) h_{\mu\nu} A_\alpha(x) A_\beta(y)$$

$$= \frac{1}{2} (\Box, h^2(z) - \delta^4(z) h_{\mu\nu}(z)) F_\alpha(\mu, \nu, A_\alpha(x) A_\beta(y).$$

(133)
CONFORMAL ANOMALIES AND THE GRAVITATIONAL...

\[ i_{\mu}^{\nu\alpha\beta}(z, y, x)h_{\mu\nu}A_\alpha(x)A_\beta(y) = (\Box, h(z) - \partial_\mu \partial_\nu h^{\mu\nu}(z))\partial_\lambda F^\lambda_\alpha(x)\partial_\rho F^{\rho\lambda}(y), \]  

(134)

\[ i_{\mu}^{\nu\alpha\beta}(z, x)h_{\mu\nu}A_\alpha(x)A_\beta(y) = \frac{1}{2} h^{\mu\nu}(z)(\Box g_{\mu\nu} - 4 \partial_\mu \partial_\nu)F^\lambda_\alpha(x)\partial_\lambda F^{\rho\lambda}(y), \]  

(135)

\[ i_{\mu}^{\nu\alpha\beta}(z, x, y)h_{\mu\nu}A_\alpha(x)A_\beta(y) = \frac{1}{2} h^{\mu\nu}(z)(\Box g_{\mu\nu} - 4 \partial_\mu \partial_\nu)F^\lambda_\alpha(x)\partial_\lambda F^{\rho\lambda}(y), \]  

(136)

\[ i_{\mu}^{\nu\alpha\beta}(z, x, y)h_{\mu\nu}A_\alpha(x)A_\beta(y) = \frac{1}{2} h^{\mu\nu}(z)(\Box g_{\mu\nu} - 4 \partial_\mu \partial_\nu)F^\lambda_\alpha(x)\partial_\lambda F^{\rho\lambda}(y), \]  

(137)

\[ i_{\mu}^{\nu\alpha\beta}(z, x, y)h_{\mu\nu}A_\alpha(x)A_\beta(y) = \frac{1}{2} h^{\mu\nu}(z)(\Box g_{\mu\nu} - 4 \partial_\mu \partial_\nu)F^\lambda_\alpha(x)\partial_\lambda F^{\rho\lambda}(y), \]  

(138)

and similar expressions for the remaining tensor structures. However, the most useful forms of the effective action involve an expansion in the fermions mass, as in the \(1/m\) formulation (the Euler-Heisenberg form) or for small \(m\). In this second case the nonlocal contributions obtained from the anomaly poles appear separated from the massive terms, showing the full-fledged implications of the anomaly. This second formulation allows a smooth massless limit, where the breaking of the conformal anomaly is entirely due to the massless fermion loops.

In the \(1/m\) case, for on-shell gauge bosons, the result turns out to be particularly simple. We obtain

\[ F_1(s, 0, 0, m^2) = \frac{7e^2}{2160\pi^2} \frac{1}{m^2} + \frac{e^2 s}{3024\pi} \frac{1}{m^3} + O\left(\frac{1}{m^6}\right). \]  

(141)

\[ F_3(s, 0, 0, m^2) = F_5(s, 0, 0, m^2) \]

\[ = \frac{e^2}{4320\pi^2} \frac{1}{m^2} + \frac{e^2 s}{60480\pi} \frac{1}{m^3} + O\left(\frac{1}{m^6}\right). \]  

(142)

\[ F_3(s, 0, 0, m^2) = -4F_3(s, 0, 0, m^2) \]  

(143)

which can be rearranged in terms of three independent tensor structures. Going to configuration space, the linearized expression of the contribution to the gravitational effective action due to the \(TJJ\) vertex, in this case, can be easily obtained in the form

\[ S_{TJJ} = \int d^4x d^4y d^4z \Gamma^{\nu\alpha\beta}(x, y, z)A_\alpha(x)A_\beta(y)h_{\mu\nu}(z) \]

\[ \quad - \frac{7e^2}{4320\pi^2 m^2} \int d^4x (\Box h - \partial_\mu \partial_\nu h_{\mu\nu}) F^2 \]

\[ \quad - \frac{e^2}{4320\pi^2 m^2} \int d^4x (\Box h F^2 - 8 \partial_\mu F^{\alpha\beta} \partial_\nu F_{\alpha\beta} h_{\mu\nu} + 4(\partial_\mu \partial_\nu F_{\alpha\beta}) F^{\alpha\beta} h_{\mu\nu}) \]

\[ \quad + \frac{11e^2}{1440\pi^2 m^2} \int d^4x T^{\mu\nu}_{ph} \Box h_{\mu\nu}. \]  

(145)

and hence the whole correlator with two on-shell photons on the external lines is

VII. THE MASSLESS (ON-SHELL) \(TJJ\) CORRELATOR

The nonlocal structure of the effective action, as we have pointed out in the previous sections, is not apparent within an expansion in \(1/m\), nor this expansion has a smooth match with the massless case.

The computation of the correlator \(\Gamma^{\nu\alpha\beta}(s, 0, 0, 0)\) hides some subtleties in the massless fermion limit (with on-shell external photons), as the form factors \(F_i\) and the tensorial structures \(t_i\) both contain the kinematical invariants \(s_1, s_2\). For this reason the limit of both factors (form factor and corresponding tensor structure) \(F_i t^{\nu\alpha\beta}\) has to be taken carefully, starting from the expression of the massless \(F_i(s; s_1, s_2, 0)\) listed in Appendix E and from the tensors \(t^{\nu\alpha\beta}\) contracted with the physical polarization tensors. In this case only few form factors survive and in particular

\[ F_1(s, 0, 0, 0) = -\frac{e^2}{18\pi^2 s}. \]  

(146)

\[ F_3(s, 0, 0, 0) = F_5(s, 0, 0, 0) = -\frac{e^2}{144\pi^2 s}. \]  

(147)

\[ F_7(s, 0, 0, 0) = -4F_3(s, 0, 0, 0). \]  

(148)

\[ F_{13,\rho}(s, 0, 0, 0) = -\frac{e^2}{144\pi^2} \left[ 12 \log \left( -\frac{s}{\mu^2} \right) - 35 \right]. \]  

(149)
\[ \Gamma_{\mu \nu \alpha \beta}(s; 0, 0, 0) = F_1(s, 0, 0, 0) \bar{\Gamma}_{\mu \nu \alpha \beta} + F_3(s, 0, 0, 0) \times (\bar{i}_1^{\mu \nu \alpha \beta} + \bar{i}_5^{\mu \nu \alpha \beta} - 4\bar{i}_7^{\mu \nu \alpha \beta}) + F_{13, R}^{\mu \nu \alpha \beta} \]
\[ = -\frac{e^2}{48\pi^2 s} \left[ (2p^\beta q^\alpha - sg^{\alpha \beta})(2p^\mu p^\nu + 2q^\mu q^\nu - sg^{\mu \nu}) \right] + F_{13, R}^{\mu \nu \alpha \beta}, \]

(150)

where \( \bar{\Gamma}_{\mu \nu \alpha \beta} \) are the tensors defined in Eqs. (125)–(127).

The study of the singularities in 1/s for this correlator requires a different analysis for \( F_1 \) and the remaining form factors, as explicitly shown in Eq. (150), where \( F_1 \) has been kept aside from the others, even if it is proportional to \( F_3 \). Indeed \( F_1 \) is the only form factor multiplying a non-zero trace tensor, \( \bar{i}_1^{\mu \nu \alpha \beta} \), and responsible for the trace anomaly. If we take the residue of the on-shell correlator for physical polarizations of the photons in the final state we see how the 4 form factors and their tensors combine in such a way that the result is different from zero as

\[ \lim_{s \to 0} \Gamma_{\mu \nu \alpha \beta}(s; 0, 0, 0) = -\frac{e^2}{12\pi^2} p^\beta q^\alpha (p^\mu p^\nu + q^\mu q^\nu), \]

(151)

where clearly each singular part in 1/s present in \( F_1, F_3, F_5, F_7 \) added up and the logarithmic behavior in s of \( F_{13} \) has been regulated by the factor s in front when taking the limit. The result shows that the pole, in this case, is coupled in the IR, as shown by the dispersive analysis.

**VII. CONCLUSIONS**

We have presented a computation of the TJJ correlator, responsible for the appearance of gauge contributions to the conformal anomaly in the effective action of gravity. We have used our results to present the general form of the gauge contributions to this action, in the limit of a weak gravitational field. One interesting feature of this correlator is the presence of an anomaly pole [16].

Usually anomaly poles are interpreted as affecting the infrared region of the correlator and appear only in one special kinematical configuration, which requires massless fermions in the loop and on-shell conditions for the external gauge lines. In general, however, the anomaly pole affects the UV region even if it is not coupled in the infrared. This surprising feature of the anomaly is present both in the case of the chiral anomaly [20] and in the conformal anomaly. Here we have extracted explicitly this behavior by a general analysis of the correlator, extending our previous study of the chiral gauge anomaly.

Indeed anomaly poles are the most interesting feature, at perturbative level, of the anomaly, being it conformal or chiral, and are described by mixed diagrams involving either a scalar (gravitational case) [16] or a pseudoscalar (chiral case) [20,31]. The connection between the infrared and the ultraviolet, signalled by the presence of these contributions, should not be too surprising in an anomalous context. The polelike behavior of an anomalous correlator is usually “captured” by a variational solution of a given anomaly equation, which implicitly assumes the presence of a pole term in the integrated functional [32]. By rediscovering the pole in perturbation theory, obviously, one can clearly conclude that variational solutions of the anomaly equations are indeed correct, although they miss homogeneous solutions to the Ward identity, that indeed must necessarily be identified by an off-shell perturbative analysis of the correlators. This is the approach followed here and in [20].

We have also seen that the identification of the massless anomaly pole allows to provide a “mixed” formulation of the effective action in which the pole is isolated from the remaining mass terms, extracted in the \( \delta_{\text{pole}} \) part of the anomalous action, which could be used for further studies. We have also emphasized that a typical 1/m expansion of the anomalous effective action fails to convey fully the presence of scaleless contributions.

There are various applications of our analysis which can be of interest for further studies. The first concerns the possible implication of these types of effective actions in cosmology, especially in inflationary scenarios where the coupling of gravity to matter via gauge interactions and the conformal anomaly plays an interesting phenomenological role. As we have stressed in the introduction, the local description of an anomalous effective action involves additional degrees of freedom which can be identified in the case of the gauge anomaly [31] as well as in the conformal case [16]. In [16] the authors describe the role of the corresponding scalar degrees of freedom in the effective action emphasizing their meaning as possible composite. In the case of an anomalous gauge theory the derivative coupling of the anomaly pole to the anomalous gauge current indicates that its nature is that of a quasi Nambu-Goldstone mode. If the parallel with chiral theories holds, one should be able to characterize the physical property of this state, including its BE condensation under the action of gravity. Similar features could be shared by the scalar state(s) described by the conformal anomaly. Of particular interest are the extensions of these analysis to the case of supersymmetric theories, in particular, to \( N = 1 \) superconformal theories, where the R-current, the supersymmetry current and the energy-momentum tensor belong to the same supermultiplet, as are their corresponding anomalies. Clearly our computation is the first step in this direction, and can be extended with the inclusion of other types of fields in the perturbative expansion, reaching, as a starting point, all the relevant fields of the standard model. In general, one could also use our approach to come with a complete description of the interplay between supersymmetry and the conformal anomaly, acting as a mediator of
the gravitational interaction, which is of phenomenological interest. Finally, we mention that our analysis could be useful in order to test, in a specific realization, perturbative results of conformal field theories in four spacetime dimensions. These studies of the TJJ correlator have been performed on rather general grounds, using conformal invariance as a unique assumption in order to infer the structure of the operator product expansion [33]. We hope to return to these points in the near future.

APPENDIX A: DEFINITIONS AND CONVENTIONS

FOR THE SCALAR INTEGRALS

We collect in this appendix all the scalar integrals involved in this computation. To set all our conventions, we start with the definition of the one-point function, or massive tadpole \( \mathcal{A}_0(m^2) \), the massive bubble \( \mathcal{B}_0(s, m^2) \) and the massive three-point function \( \mathcal{C}_0(s, s_1, s_2, m^2) \)

\[
\mathcal{A}_0(m^2) = \frac{1}{i\pi^2} \int d^dl \frac{1}{l^2 - m^2} = m^2 \left[ \frac{1}{\bar{\epsilon}} + 1 - \log \left( \frac{m^2}{\mu^2} \right) \right].
\]

\[
\mathcal{B}_0(k^2, m^2) = \frac{1}{i\pi^2} \int d^dl \frac{1}{(l^2 - m^2)((l - k)^2 - m^2)} = \frac{1}{\bar{\epsilon}} + 2 - \log \left( \frac{m^2}{\mu^2} \right) - a_3 \log \left( \frac{a_3 + 1}{a_3 - 1} \right).
\]

\[
\mathcal{C}_0(s, s_1, s_2, m^2)
= \frac{1}{i\pi^2} \int d^dl \frac{1}{(l^2 - m^2)((l - q)^2 - m^2)((l + p)^2 - m^2)}
= \frac{1}{\bar{\epsilon}} \sum_{i=1}^{3} \left[ \frac{\text{Li}_2}{a_i} - \frac{b_i - 1}{a_i - b_i} - \frac{\text{Li}_2}{a_i} - \frac{b_i - 1}{a_i - b_i} \right]
+ \text{Li}_2 \left[ \frac{a_i - b_i}{a_i + b_i} \right].
\]

with

\[
a_i = \sqrt{1 - \frac{4m^2}{s_i}}, \quad b_i = -\frac{s_i + s_j + s_k}{\sqrt{\sigma}}.
\]

where \( s_3 = s \) and in the last equation \( i = 1, 2, 3 \) and \( j, k \neq i \). The one-point and two-point functions written before in \( n = 4 - 2\epsilon \) dimensions are divergent with the singular parts given by

\[
\mathcal{A}_0(m^2)_{\text{sing}} \to \frac{1}{\bar{\epsilon}} m^2, \quad \mathcal{B}_0(s, m^2)_{\text{sing}} \to \frac{1}{\bar{\epsilon}}.
\]

with

\[
\frac{1}{\bar{\epsilon}} = \frac{1}{\epsilon} - \gamma - \ln \pi.
\]

We use two finite combinations of scalar functions given by

\[
\mathcal{D}_i = \mathcal{D}_i(s, s_i, m^2) = \mathcal{B}_0(s, m^2) - \mathcal{B}_0(s_i, m^2)
= \left[ a_i \log \frac{a_i + 1}{a_i - 1} - a_3 \log \frac{a_3 + 1}{a_3 - 1} \right]. \quad i = 1, 2.
\]

The scalar integrals \( \mathcal{C}_0(s, 0, 0, m^2) \) and \( \mathcal{D}(s, 0, 0, m^2) \) are the \( \{s_1 \to 0, s_2 \to 0\} \) limits of the generic functions \( \mathcal{C}_0(s, s_1, s_2, m^2) \) and \( \mathcal{D}_i(s, s_i, m^2) \)

\[
\mathcal{C}_0(s, 0, 0, m^2) = \frac{1}{2s} \log^2 \frac{a_3 + 1}{a_3 - 1}, \quad \mathcal{D}_i(s, 0, 0, m^2) = \frac{1}{2s} \log^2 \frac{a_3 + 1}{a_3 - 1}.
\]

The master integrals denoted by \( \mathcal{B}_0(s, 0), \mathcal{D}_i(s, s_i, 0) \) \( i = 1, 2 \) and \( \mathcal{C}_0(s, s_1, s_2, 0) \) are consistently redefined for \( m < 0 \) and \( s < 0 \) as

\[
\mathcal{B}_0(s, 0) = \left[ \frac{1}{\bar{\epsilon}} - \log \left( \frac{s}{\mu^2} \right) + 2 \right].
\]

\[
\mathcal{D}_i(s, s_i, 0) = \mathcal{B}_0(s, 0) - \mathcal{B}_0(s_i, 0) = \log \left( \frac{s_i}{s} \right) \quad i = 1, 2.
\]

\[
\mathcal{C}_0(s, s_1, s_2, 0) = \frac{1}{s} \Phi(x, y),
\]

where \( \mu \) is the renormalization scale and the function \( \Phi(x, y) \) is defined as [34]

\[
\Phi(x, y) = \frac{1}{\lambda} \left\{ 2[\text{Li}_2(-\rho x) + \text{Li}_2(-\rho y)] + \ln x \ln \frac{1 + \rho y}{1 + \rho x} \right. \right. + \ln(\rho x) \ln(\rho y) + \frac{\pi^2}{3} \right\}.
\]
difference of two functions $B_0$, so that the $D_i$’s are well-defined; the three-point master integral is convergent.

**APPENDIX B: ALTERNATIVE CONDITIONS ON THE CORRELATOR IN THE MASSLESS CASE**

As we have mentioned, one can follow an entirely different approach in order to fix the expression of the correlator. This is based on the requirement that the trace anomaly satisfies a well known operatorial relation which is imposed on the matrix elements at nonzero momentum. Specifically we proceed as follows and illustrate this point in the massless limit. We impose the value of the trace anomaly as a defining condition on the whole amplitude, so

\[
\text{Eq. (B1) } \Rightarrow \left\{ \begin{array}{l}
4 \frac{A_0}{p^2} - A_7 + 2A_9 - A_{12} = 0,
\vspace{1mm}
c - 4A_{37} + 4A_{42} + A_4 p \cdot p - 2A_6 p \cdot p - 2A_{11} p \cdot q + 2A_{14} q \cdot q + A_{16} q \cdot q = 0,
\end{array} \right.
\]

whose solutions for $A_{41}$ and $A_{37}$ read as

\[
A_{41} = \frac{p \cdot q}{4} (A_7 - 2A_9 + A_{12}) \quad (B3)
\]

\[
A_{37} + A_{42} = \frac{1}{4} \left[ -c - A_4 p \cdot p + 2A_6 p \cdot p - 2A_{11} p \cdot q - 2A_{14} q \cdot q - A_{16} q \cdot q \right]. \quad (B4)
\]

As seen from the last equation, the second solution returns the sum of two UV divergent amplitudes, $A_{37}$ and $A_{42}$. However, an explicit computation shows that in the mapping between the two sets of $A_i$ and $F_i$ these two amplitudes appear in such a way that their divergences cancel. Therefore, reinserting the expressions of $A_{41}$ and $A_{37}$ extracted from Eq. (B4) into the expression of $\Gamma_{\mu\nu\alpha\beta}(p, q)$ one finds another mapping between the form factors $A_i$ and $F_i$, as previously done in Eqs. (75)–(87)

\[
F_1 = \frac{c}{3k \cdot k}, \quad (B5)
\]

\[
F_2 = 0, \quad (B6)
\]

\[
F_3 = \frac{A_4}{4} - \frac{c}{12k \cdot k}, \quad (B7)
\]

\[
F_4 = \frac{A_7}{4p \cdot p}, \quad (B8)
\]

\[
F_5 = \frac{A_{16}}{4} - \frac{c}{12k \cdot k}, \quad (B9)
\]

\[
F_6 = \frac{A_{12}}{4q \cdot q}, \quad (B10)
\]

\[
F_7 = -\frac{c}{6k \cdot k} + \frac{A_{11}}{2} + \frac{(A_9 p \cdot p + A_{14} p \cdot q) q \cdot q}{2p \cdot q^2} + \frac{p \cdot p (A_6 p \cdot q + A_0 q \cdot q)}{2p \cdot q^2}, \quad (B11)
\]

that the (new) request $c'$ replacing the (old) $c$ in Sec. III A will be $c'$ the nonzero anomaly trace in the massless limit. As the first two conditions (a) and (b), respectively, the $\{\mu \leftrightarrow \nu\}$ symmetry and the vector current conservation, remain the same as in Sec. III A, we continue illustrating the modifications due to this approach from this point on. The third condition is given by

\[
g_{\mu\nu} \Gamma_{\mu\nu\alpha\beta}(p, q) = c u^{\alpha\beta}(p, q). \quad (B1)
\]

where $c$ is related to the usual QED $\beta$-function as $c = -\frac{\beta}{2}$. The resulting system is

\[
F_8 = -\frac{A_9}{2p \cdot q}, \quad (B12)
\]

\[
F_9 = \frac{A_6}{p \cdot q} + A_9 \frac{q \cdot q}{p \cdot q^2}, \quad (B13)
\]

\[
F_{10} = A_9 \frac{p \cdot p}{p \cdot q^2} + \frac{A_{14}}{p \cdot q}, \quad (B14)
\]

\[
F_{11} = \frac{A_{12}}{2p \cdot q} - \frac{A_2}{2p \cdot p}, \quad (B15)
\]

\[
F_{12} = \frac{A_3}{2p \cdot p} + \frac{A_7}{2p \cdot p}, \quad (B16)
\]

\[
F_{13} = \frac{1}{4p \cdot q} \left[ 2A_{11} p \cdot q^2 + c p \cdot q + 4A_{42} p \cdot q \right.
\]

\[
+ A_4 p \cdot p \cdot q + 2A_6 p \cdot p \cdot q + 2A_{14} q \cdot q \cdot q
\]

\[
+ A_{16} q \cdot q \cdot q + 4A_9 p \cdot p \cdot q \cdot q \right]. \quad (B17)
\]

This new mapping leaves the invariant amplitudes from $F_9$ to $F_{12}$ the same as before, so the condition $c'$, i.e. the WI derived from Eq. (36) and $c'$ are perfectly equivalent in determining these 4 form factors.

**APPENDIX C: COMPARISON WITH THE PARAMETRIC APPROACH AND NUMERICAL CHECKS**

The parametric approach of [16] allows, by combining the denominators of the various tensor amplitudes, to give parametric expressions for the form factors $F_i$ starting from a set of scalar parametric integrals. Our results correspond to an explicit computation of these integrals. We will not give each integral separately, since they are rather lengthy. The mapping between the $F_i$’s in the parametric form and our expressions allow to perform numerical checks of our result. We have perfect agreement between the parametric forms derived in [16], computed numeri-
CONFORMAL ANOMALIES AND THE GRAVITATIONAL ... 

cally, and our explicit expressions in all the euclidean regions of the external momenta. We briefly clarify this point.

Explicit formulas for all twelve finite coefficient functions may be given in the Feynman parametrized form,

\[
C_i(k^2; p^2, q^2) = \frac{e^2}{4\pi^2} \int_0^1 dx \int_0^{1-x} dy \frac{c_i(x, y)}{p^2 x (1-x) + q^2 y (1-y) + 2xy p \cdot q + m^2},
\]

(C1)

where the polynomials \(c_i(x, y)\) for \(i = 1, \ldots, 12\) are listed in Table III.

\[
F_1 = \frac{C_7 + C_8 + C_9}{3} + \frac{p^2}{3k^2} (-C_1 + C_3 + C_8 - C_9) + \frac{q^2}{3k^2} (-C_7 + C_8 + C_{10} - C_{12}),
\]

(C2)

\[
F_3 = \frac{2C_7 - C_8 - C_9}{12} + \frac{p^2}{12k^2} (C_1 - C_3 - C_8 + C_9) + \frac{q^2}{12k^2} (C_7 - C_8 - C_{10} + C_{12}),
\]

(C3)

\[
F_5 = \frac{-C_7 - C_8 + 2C_9}{12} + \frac{p^2}{12k^2} (C_1 - C_3 - C_8 + C_9) + \frac{q^2}{12k^2} (C_7 - C_8 - C_{10} + C_{12}),
\]

(C4)

\[
F_7 = \frac{-C_7 + 2C_8 - C_9}{6} + \frac{p^2}{6k^2} (C_1 - C_3 - C_8 + C_9) + \frac{q^2}{6k^2} (C_7 - C_8 - C_{10} + C_{12}) + \frac{p^2 q^2}{(p \cdot q)^2} C_5 + \frac{p^2 C_2 + q^2 C_{11}}{2(p \cdot q)},
\]

(C5)

Finally, numerical checks on \(F_{13}\) are performed on the UV convergent amplitude.

| \(j\) | \(C_j = \text{coefficient of}\) \(c_i(x, y)\) |

where the scalar two-point functions have been renormalized by the subtraction of the UV 1/\(\epsilon\) pole.

**APPENDIX D: THE MASSIVE INVARIANT AMPLITUDES**

The off-shell massive form factors \(F_i\), with \((i)\ s \neq 0\ s_1 \neq 0\ s_2 \neq 0\ \ m \neq 0\) and with \(\gamma \equiv s - s_1 - s_2, \sigma \equiv -2(s_1 + s_2)s + (s_1 - s_2)^2\) are given by\(^1\)

\[
F_1(s; s_1, s_2, m^2) = \frac{e^2 \gamma^2 m^2}{3\pi^2 \sigma} + \frac{e^2 D_2(s, s_2, m^2) s_2 [s^2 + 4s_1 s - 2s_2 s - 5s_1^2 + s_2^2 + 4s_1 s_2] m^2}{3\pi^2 \sigma^2} - \frac{e^2}{18\pi^2 s} \left[ 2D_1(s, s_1, m^2) s_1 [(s - s_1) + 5s_2 - 4(s + s_1) s_2] m^2 - e^2 C_0(s, s_1, m^2) \right] \times \left[ \frac{m^2 \gamma [(s - s_1)^3 - s^3 - (3s + s_1)^2] - 2m^4 \gamma}{3\pi^2 \sigma^2} \right],
\]

(D1)

\[
F_2(s; s_1, s_2, m^2) = -\frac{e^2 m^2}{3\pi^2 \sigma} \left[ -2e^2 D_2(s, s_2, m^2)(s - s_1)^2 - 2s_2 s + (s + s_1) s_2^2 m^2 - 2e^2 D_1(s, s_1, m^2) s_2 m^2 \right] \times \left[ \frac{4m^4}{3\pi^2 \sigma^2} + \frac{m^2}{3\pi^2 \sigma^2} [s^3 - (s + s_1)s^3 - (s_1 - s_2)(s_1 + s_2)] \right],
\]

(D2)

\[
F_3(s; s_1, s_2, m^2) = F_5(s; s_2, s_1, m^2)
\]

\[
= -\frac{e^2}{144\pi^2 \sigma} [(s_2 + 3(s_1 - 4 s_2)) s_2^4 + 6(3s_1 - 7 s_2) s_2 s^4 + 2(5s_1 - 69 s_2) s_2^2 + 117 s_2^2 s_1 + 23 s_2) s^3 - 3(5s_1^4 - 62 s_2 s_1^3 + 72 s_2^2 s_1^2 + 50 s_2 s_1 + 7 s_2^2) s^2 + 3(s_1 - s_2)^2 (3s_1 - 24 s_2 s_1^2 - 33 s_2 s_1 + 25 s_2^3) s - 2(s_1 - s_2) \] \quad \begin{align*}
&\times \left[ \frac{4m^4}{12\pi^2 \sigma^2} + \frac{m^2}{3\pi^2 \sigma^2} [s^3 - (s + s_1)s^3 - (s_1 - s_2)(s_1 + s_2)] \right].
\end{align*}

\]

(D3)

\(^1\)We use boldfaced notation to facilitate their identification in the lengthier expressions.
\[ F_4(s; s_1, s_2, m^2) = F_4(s; s_2, s_1, m^2) \]
\[
= \frac{e^2 m^2}{6 \pi^2 s^{\sigma^2_s}} \left[ 3 s^3 - 2(2s_1 + 3s_2)s^2 + (-s_1^3 + 6s_2s_1 + 3s_1^2)s + 2s_1(s_1 - s_2)^2 \right]
\]
\[
+ \frac{e^2}{12 \pi^2 s^{\sigma^2_s}} \left[ B_0(s, m^2)m^2 - \mathcal{A}_0(m^2) \right] \left[ 3 s^3 - 2(2s_1 + 3s_2)s^2 + (-s_1^3 + 4s_2s_1 + 3s_1^2)s \right.
\]
\[
+ 2s_1(s_1 - s_2)^2 \right] + \frac{e^2}{24 \pi^2 s^{\sigma^2_s}} \left[ -s_1^3 + (6s + 11s_1)s_1^2 - (14s^2 + s_1s + 5s_1^2)s^2 \right.
\]
\[
+ (16s^3 - 35s_1s^2 + 46s_1^2s - 15s_1^3)s_2^2 - (s - s_1)^2(9s^2 - 11s_1s - 6s_1^2)s_2 + 2(s - s_1)^2(s + 2s_1) \right]
\]
\[
- e^2 D_2(s, s_1, m^2) \left[ \frac{m^2}{12 \pi^2 s^{\sigma^2_s}} \left[ -2(2s + s_1)(s - s_1)^4 + (3s^2 - 43s_1s + 2s_1^2)s_2(s - s_1)^2 \right.ight.
\]
\[
+ (9s + 4s_1)s_1^3 + (-23s^2 + 29s_1s - 10s_1^2)s_2^2 + (15s^3 + 2s_1s^2 + 5s_1^2s + 6s_1^3)s_2^3 \right.
\]
\[
- \frac{1}{48 \pi^2 s^{\sigma^2_s}} \left[ (s + s_1)(s - s_1)^3 - 4(4s^2 - 14s_1s - 5s_1^2)s_2(s - s_1)^4 + (35s^3 - 119s_1s^2 \right.
\]
\[
+ 169s_1^2s - 13s_1^3s_2^2(s - s_1)^2 + (s - 3s_1)s_2^3 - 8(s^2 + 9s_1s + 7s_1^2)s_2^4 + (25s^3 + 159s_1s^2 \right.
\]
\[
- 197s_1^2s + 157s_1^3)s_2^4 + 4(-10s^4 + 21s_1^2s^2 + 28s_1^3s - 27s_1^2s_2^2) \right] + e^2 D_1(s, s_1, s_2, m^2) \right]
\]
\[
\times \left[ \frac{m^2}{12 \pi^2 s^{\sigma^2_s}} \left[ (2s^5 + (15s_1 - 8s_2)s^4 + (-53s_1^2 - 5s_2s_1 + 12s_1^2)s^3 + (49s_1^3 + 46s_2s_1^2 \right.
\]
\[
- 33s_1^2s_1 - 8s_2^3)s^2 - (s_1 - s_2)(9s_1^3 + 52s_2s_1^2 + 23s_1^2s_1 + 2s_1^2)s - 2s_1(s_1 - s_2)^3(2s_1 + s_2) \right.
\]
\[
+ \frac{1}{48 \pi^2 s^{\sigma^2_s}} \left[ (s_1^6 + 4(6s + 11s_1)s_1^5 + (-87s^2 + 106s_1s - 91s_1^2)s_1^4 + 4(22s^3 - 69s_1s^2 + 40s_1^2s + s_1^3)s_2^3 \right.
\]
\[
+ (s - s_1)(3s^3 - 29s_1s^2 + 209s_1^2s - 79s_1^3)s_2^2 - 8(s - s_1)^3(6s^2 - 13s_1s - 4s_1^2)s_2 \right.
\]
\[
+ (s - s_1)^5(19s + 5s_1)) \right] + e^2 C_0(s, s_1, s_2, m^2) \left[ \frac{m^2}{6 \pi^2 s^{\sigma^2_s}} \left[ \sigma(3s + 2s_1) \right] \right. \left. + 18s_2 \right] \right]
\]
\[
- \frac{m^2}{24 \pi^2 s^{\sigma^2_s}} \left[ -\frac{\sigma^2}{ss_1} (9s^2 + (59s_1 + 3s_2)s + 2s_1(s_1 + s_2)) + 12(3s^2 - 3(2s_1 + 7s_2)s \right.
\]
\[
+ s_1(3s_1 - 17s_2))s + 720ss_1((s - s_1)^3 - (s + s_1)s^2) \right] - \frac{1}{16 \pi^2 s^{\sigma^2_s}} \left[ -2s(s - s_1)^6 \right.
\]
\[

\end{align*}
\]

\[(E7)\]
As already noticed above for the case of the massive form factors the last one, i.e. \( F_{13}(s; s_1, s_2, 0) \), has been affected by the renormalization procedure for which the one-loop transverse photon propagator with a virtual pair of massless fermions is given by

\[
\Pi_R(s, 0) = -\frac{e^2}{12\pi^3} \left[ 5 - \log \left( -\frac{s}{\mu^2} \right) \right].
\]

where the dependence on the renormalization scale \( \mu \) remains explicit.

**APPENDIX F: THE ASYMPTOTIC BEHAVIOR OF THE OFF-SHELL MASSLESS \((TJJ)\) CORRELATOR**

We present here the asymptotic expression of the form factor in the high energy limit. The leading contributions to the expansion in each expression come from the pole singularities (conformal or anomalous) except for \( F_{13} \) which has a constant asymptotic term.

\[
F_1(s, s_1, s_2, 0) = -\frac{e^2}{18\pi^3 s}, \quad F_2(s, s_1, s_2, 0) = 0, \quad O\left(\frac{1}{s^2}\right).
\]

\[
F_3(s, s_1, s_2, 0) = -\frac{e^2}{144\pi^3 s} - \frac{e^2}{48\pi^3 s^2} \left[ s_1 + 6s_2 + s log\left(\frac{s_1}{s}\right) + 3s_2 log\left(\frac{s_2}{s}\right) \right] + O\left(\frac{1}{s^3}\right).
\]

\[
F_4(s, s_1, s_2, 0) = \frac{e^2}{48\pi^3 s_1 s} \left[ 3 log\left(\frac{s_2}{s}\right) + 4 \right] + \frac{e^2}{48\pi^3 s_1 s^2} \left[ 2\pi^2 s_1 + 16s_1 + 6s_2 + 19s_1 log\left(\frac{s_1}{s}\right) \right] + log\left(\frac{s_2}{s}\right) \left[ 9s_1 + 8s_2 + 6s_1 log\left(\frac{s_1}{s}\right) \right] + O\left(\frac{1}{s^3}\right).
\]
\[ F_7(s, s_1, s_2, 0) = \frac{e^2}{36\pi^3 s} s^2 + \frac{e^2}{24\pi^2 s^2} \left[ 3(s_1 + s_2) + 2s_1 \log \left( \frac{s_1}{s} \right) + 2s_2 \log \left( \frac{s_2}{s} \right) \right]. \]  

(F4)

\[ F_8(s, s_1, s_2, 0) = -\frac{e^2}{24\pi^2 s^2} \left[ 3 \log \left( \frac{s_1}{s} \right) + 3 \log \left( \frac{s_2}{s} \right) + 10 \right] + O\left( \frac{1}{s^2} \right). \]  

(F5)

\[ F_9(s, s_1, s_2, 0) = -\frac{e^2}{12\pi^2 s^2} \left[ \log \left( \frac{s_1}{s} \right) + 1 \right] + O\left( \frac{1}{s^3} \right). \]  

(F6)

\[ F_{11}(s, s_1, s_2, 0) = \frac{e^2}{24\pi^2 s s_1} \left[ 3 \log \left( \frac{s_1}{s} \right) + 4 \right] + \frac{e^2}{24\pi^2 s s_2} \left[ 6s_1 + 2\pi^2 s_2 + 12s_2 + 17s_2 \log \left( \frac{s_2}{s} \right) \right] + \log \left( \frac{s_1}{s} \right) \left[ 8s_1 + 9s_2 + 6s_2 \log \left( \frac{s_2}{s} \right) \right] + O\left( \frac{1}{s^3} \right). \]  

(F7)

\[ F_{13}(s, s_1, s_2, 0) = -\frac{1}{2} \left[ \Pi_R(s_1, 0) + \Pi_R(s_2, 0) \right] + \frac{e^2}{24\pi^2} \left[ \log \left( \frac{s_1}{s} \right) + \log \left( \frac{s_2}{s} \right) + \frac{5}{2} \right] + \frac{e^2}{12\pi^2 s} \left[ s_1 + s_2 + 2s_1 \log \left( \frac{s_1}{s} \right) + 2s_2 \log \left( \frac{s_2}{s} \right) \right] \left[ 2(s_1^2 + (3 + \pi^2)s_1 + s_2^2) + s_2(13s_1 + 6s_2) \log \left( \frac{s_2}{s} \right) + s_1 \log \left( \frac{s_1}{s} \right) \left( 6s_1 + 13s_2 + 6s_2 \log \left( \frac{s_2}{s} \right) \right) \right] + O\left( \frac{1}{s^3} \right). \]  

(F8)

\section*{Appendix G: The Asymptotic Behavior of the On-Shell Massive \(\langle TJJ \rangle\) Correlator}

This appendix contains the asymptotic expansion of the relevant on-shell massive form factors, that is their dominant contributions as \( s \to \infty \) with \( s > 0 \) after taking into account the suitable analytic continuation. They result

\[ F_4(s, 0, 0, m^2) = -\frac{e^2}{18\pi^2 s} + \frac{e^2 m^2}{12\pi^2 s^2} \left[ 4 - \log^2 \left( \frac{m^2}{s} \right) - 2i\pi \log \left( \frac{m^2}{s} \right) + \pi^2 \right] + O\left( \frac{1}{s^3} \right). \]  

(G1)

\[ F_5(s, 0, 0, m^2) = F_5(s, 0, 0, m^2) = -4F_3(s, 0, 0, m^2), \]  

(G2)

\[ F_{13,R}(s, 0, 0, m^2) = \frac{e^2}{144\pi^2} \left[ 12 \log \left( \frac{m^2}{s} \right) + 35 + 12i\pi \right] + \frac{e^2 m^2}{8\pi^2 s} \left[ \log^2 \left( \frac{m^2}{s} \right) + 10 - \pi^2 + 2i\pi + (2 + 2i\pi) \log \left( \frac{m^2}{s} \right) \right] \left[ -\log^2 \left( \frac{m^2}{s} \right) + (2 - 2i\pi) \log \left( \frac{m^2}{s} \right) + \pi^2 + 2i\pi - 3 \right] + O\left( \frac{1}{s^3} \right). \]
