The purpose of this study was to determine the anatomical aspects, mechanisms, risk factors and appropriate management of development of pneumothorax during a routine colonoscopy. A systematic search of the literature (MEDLINE, Embase and Google Scholar) revealed 21 individually documented patients of pneumothorax following a colonoscopy, published till December 2015. One additional patient treated at our center was added. A pooled analysis of these 22 patients was performed including patient characteristics, indication of colonoscopy, any added procedure, presenting symptoms, risk factors and treatment given. The review suggested that various risk factors may be female gender, therapeutic interventions, difficult colonoscopy and underlying bowel pathology. Diagnosis of this condition requires a high index of suspicion and treatment should be tailored to individual needs.

**INTRODUCTION**

Colonoscopy is a commonly performed procedure with perforation, although rare, being the most serious complication. The incidence of perforation after diagnostic colonoscopy has been reported to be 0.03% to 0.65% and 0.07% to 2.14%, after a therapeutic manoeuvre. A wide variety of clinical manifestations after colonoscopy, due to extra luminal accumulation of air, have been reported including pneumoperitoneum, pneumoretroperitoneum, pneumomediastinum, surgical emphysema and pneumoscrotum. In this article, we have described an even rarer complication, pneumothorax, following a diagnostic colonoscopy and have performed a pooled analysis of all individually documented cases from literature including the patient managed at authors’ institution to determine the anatomical aspects, mechanisms, risk factors and appropriate management.

**MATERIALS AND METHODS**

A systematic review was performed to identify all relevant literature on pneumothorax after colonoscopy. Two authors (KH, AG) performed systematic Medical Subject Heading (MeSH) search using PubMed, Embase and Google Scholar. The search was limited to Humans and Adults. Time frame for search was from the inception of databases till July 2015 following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement. Keywords used for search included ‘Pneumothorax’ AND ‘colonoscopy’. Advanced search options including synonyms, partial word and combinations were used. Bibliographies of the retrieved articles were hand searched for further articles.

Studies pertaining to pneumothorax following colonoscopy were included. Exclusion criteria were patients with diaphragmatic hernia resulting in intrathoracic colon and extraperitoneal air leaks without pneumothorax.

A total of 21 papers met the inclusion criteria out of 66 non duplicate citations identified using PubMed, Embase and Google Scholar databases (Fig. 1).
RESULTS

A literature search revealed a total of 22 reported cases of pneumothorax following a colonoscopy, including the one case presenting at authors’ institution, since the first case was reported in 1975 (Table 1). Of these patients, majority were females (Female:Male=17:5). The median age was 65 years (47–89 years). Eight of these procedures were colonoscopy only without any biopsies or intervention, whereas in thirteen cases either biopsies (n=3) or some form of intervention was carried out (sigmoid polypectomy [n=5], caecal polypectomy [n=2], balloon dilatation [n=1], evacuation of impacted stools [n=1]). Pneumothorax was right sided in 11 cases, left sided in 4 cases and bilateral in 7 cases. The most common presenting symptoms were chest pain, dyspnoea, surgical emphysema and abdominal pain. Simple chest drainage was used in 9 patients, chest drain and laparotomy was performed in 11 patients and conservative management was successful on 2 occasions. In 8 patients the colon was normal whereas in the other 14 patients some form of underlying bowel pathology was present (Table 2).

DISCUSSION

Colonoscopic complications including perforation and massive bleeding are infrequent, but can cause very serious consequences and even lead to a fatal outcome. Various mechanisms resulting in colonoscopic perforations include direct mechanical trauma, thermal injury from electrocautery and pneumatic barotrauma from excessive air insufflation. Excessive pressure causes splitting of the serosa and muscularis propria fibres with resulting herniation of mucosa. This herniated mucosa may perforate leading to overt perforation or become permeable to air and thus resulting in extraluminal air without actual perforation. An investigative study in cadaveric specimens by Brayko showed that these serosal tears occur at a pressure of 202±15 mm Hg and mucosal ruptures can happen at pressures of 226±14 mm Hg.

Pneumothorax and extraperitoneal accumulation of air after colonoscopy is very rare. The anatomical basis of this phenomenon can be explained by the fact that continuity exists between the visceral space of the neck, thorax and abdomen via a fascial compartment. An air leak in any one of these areas, for instance from retroperitoneal colon or rectal perforation, can potentially reach these intercommunicating areas along the fascial/perivascular planes, resulting in pneumomediastinum, pneumopericardium and surgical emphysema over the torso and the neck. A pneumothorax can result when pneumomediastinum decompresses through the mediastinal pleura into the pleural cavity. Alternatively, free intraperitoneal air can enter the pleural cavity via small
Another possibility is air tracking from perianal fistulas into the retroperitoneum.

In this review a few potential risk factors for pneumothorax following colonoscopy have been identified. This complication has been found to be more common in females (81% of the cases). This can be explained by the fact that colonoscopy is found to be difficult in females due to a longer colon, deeper pelvis and low pain threshold. Authors feel that this may lead to overinsufflation and pneumatic trauma. Another risk factor may be underlying bowel pathology. In the current analysis, diverticular disease was found to be the most common underlying pathology, followed by inflammatory bowel disease (IBD) and previous colonic resection. Taking a biopsy or intervention in the form of polypectomy was another possible risk factor which was present in 62 percent of patients (Table 2).

Management is individualised in cases of pneumothoraces following colonoscopy and may include conservative management, chest tube alone or surgical intervention. Close observation is mandatory for cases managed conservatively and surgical treatment depends on the patient's overall general condition, bowel preparation, timing of surgery and degree of intra-abdominal contamination. The majority of the patients in this review were treated by chest drain whereas nearly half of the patients underwent laparotomy as well. Two patients were managed conservatively without any intervention. Out of the 11 patients who underwent laparotomy, overt perforation was found in eight patients including the present case. Described surgical treatments involved simple repair of the perforation, resection and primary anastomosis as well as resection and stoma.

### Table 1. Various Studies Reporting Pneumothorax Associated with Colonoscopy

| Study | Year | Age | Sex | Primary procedure | Side of pneumothorax | Intervention | Intraoperative finding |
|-------|------|-----|-----|-------------------|----------------------|-------------|------------------------|
| Present Case | 2014 | 50 | F | Diagnostic | Right | Chest tube+laparotomy | No perforation |
| Dehal et al. | 2014 | 55 | M | Diagnostic+Biopsies | Left | Chest tube+laparotomy | No perforation |
| Pourmand et al. | 2013 | 84 | F | Diagnostic | Right | Chest tube | - |
| Sheikh et al. | 2013 | 56 | F | Diagnostic | Right | Chest tube | - |
| Duri et al. | 2013 | 65 | F | Polypectomy | Bilateral | Chest tube | - |
| Bonner et al. | 2013 | 50 | F | Polypectomy Sigmoid | Right | Chest tube | - |
| Gorantla et al. | 2012 | 50 | F | Polypectomy Caecum | Right | Chest tube | - |
| Kipple | 2010 | 78 | M | Polypectomy Sigmoid | Bilateral | Chest tube+laparotomy | Sigmoid perforation |
| Thimmampuram et al. | 2010 | 49 | F | Biopsies | Bilateral | Chest tube | - |
| Chan et al. | 2010 | 77 | F | Balloon dilatation | Bilateral | Chest tube | - |
| Ignjatović et al. | 2009 | 54 | M | Polypectomy Sigmoid | Left | Chest tube+laparotomy | Sigmoid perforation |
| Marwan et al. | 2007 | 89 | F | Diagnostic | Right | Conservative | - |
| Lovisetto et al. | 2007 | 75 | F | Diagnostic | | Chest tube+laparoscopy | Diverticular perforation |
| Zeno et al. | 2006 | 64 | F | Therapeutic colonoscopy for impacted faecolith | Right | Chest tube+laparotomy | Sigmoid perforation |
| Ball et al. | 2006 | 77 | F | Diagnostic | Bilateral | Chest tube+laparotomy | Ileocolic anastomosis perforation |
| Hearnshaw et al. | 2004 | 80 | F | Polypectomy Sigmoid | Right | Chest tube+laparotomy | No perforation |
| Webb | 1998 | 72 | F | Diagnostic | Bilateral | Chest tube | - |
| Ho et al. | 1996 | 68 | M | Polypectomy Caecum | Right | Chest tube+laparotomy | Caecal perforation |

CONCLUSION

Pneumothorax is an exceedingly rare complication of colonoscopy, a commonly performed diagnostic procedure. Various risk factors may be female gender, any form of intervention, difficult colonoscopy and underlying bowel pathology. We are likely to see more such cases in future as a result of an increasing number of colonoscopies being performed for bowel cancer screening. Diagnosis of this condition requires a high index of suspicion and treatment is tailored to individual needs. Clinical judgement based on the patient's signs and symptoms should be made to proceed with laparotomy, as many of these patients can be managed with simpler interventions such as chest drain.
