An exhaustive list of isotropic apocalyptic scenarios

(Dated: 27 September 2016)

We study the possible types of future singularities in the isotropic homogeneous cosmological models for the arbitrary equation of state of the contents of the Universe. We obtain all known types of these singularities as well as two new types using a simple approach. No additional singularity types are possible. We name the new singularities type “Big Squeeze” and “Little Freeze”. The “Big Squeeze” is possible only in the flat Universe after a finite time interval. The density of the matter and dark energy tends to zero and its pressure to minus infinity. This requires the dark energy with a specific equation of state that has the same asymptotical behaviour at low densities as the generalised Chaplygin gas. The “Little Freeze” involves an eternal expansion of the Universe. Some solutions can mimic the ΛCDM model.

I. INTRODUCTION

During almost a century, cosmologists considered only two possible scenarios of the future of our Universe – an eternal expansion of open or flat Universe or future recollapse of the closed Universe with the “Big Crunch”. Nowadays we know that the Universe contains not only several types of matter, including the dark matter, baryonic matter and massless particles, but also the mysterious dark energy (DE). We know about its existence only for the last few decades. Honestly, we know very little about DE properties, in particular about the DE equation of state.

Even for the simplest type of the DE equation of state

\[ p = w \rho \]

with \( w = \text{const} \), where \( p \) is the pressure and \( \rho \) is the mass density, the Universe can meet its end in absolutely different way. If \( w < -1 \) we deal with so-called phantom energy. In this case during the finite time period the matter and energy density, the Hubble parameter \( H \) and the scale factor of the Universe \( a \) increase to infinity. Such type of possible future singularity was discovered in [1] and called “Big Rip”.

Note that the latest estimations of the \( w \) value do not reject this possibility. The data on the cosmic microwave background spectra from the Planck and WMAP satellites together with ground measurements and data from baryonic acoustic oscillations (BAO) provide the estimation \( w = -1.13^{+0.23}_{-0.25} \) at 95% confidence level (CL) [2]. The 9-year data from the WMAP satellite plus the determination of the Hubble constant and BAO data provide estimations \( w = -1.073^{+0.090}_{-0.089} \) for the flat Universe and \( w = -1.19^{+0.12}_{-0.12} \) for the non-flat Universe [2] at 68% CL. Adding 472 type Ia supernovae data improves these estimations to \( w = -1.084 \pm 0.063 \) and \( w = -1.122^{+0.068}_{-0.067} \), respectively [3].

Thus, the possibility of the “Big Rip” sealing the fate of the Universe is not to be taken lightly. This is not the only theoretically possible type of cosmological singularity except “Big Bang” and “Big Crunch”. Their first classification was carried out in the paper [4]. Four possible types were found for the singularities at \( t = t_0 \) with finite \( t_0 \). They include:

- **Type I**: \( a, \rho, |p| \rightarrow \infty \) (“Big Rip”)
- **Type II**: \( a \rightarrow a_0; \rho \rightarrow \rho_0; |p| \rightarrow \infty \) (“sudden”)
- **Type III**: \( a \rightarrow a_0; \rho, |p| \rightarrow \infty \) (it was named “Big Freeze” in [4])
- **Type IV**: \( a \rightarrow a_0; \rho, |p| \rightarrow 0 \) and higher derivatives of the Hubble parameter \( H \) diverge.

In the more recent classification [6], type IV singularities are divided into type IV and type V, introduced in [7], but we stick to the classification [4]. There are some singularities with \( t_0 = \infty \), too. The “Little Rip” singularity [8], similar to the “Big Rip”, but with eternal expansion is among them.

Some types of singularities were found and demonstrated for some specific equations of state. Cosmologists considered the particular cases of the phantom generalised Chaplygin gas equation of state in [2], tachyon field in [9], scalar fields with specific potentials, etc. Naturally, a question arose, whether all the possible singularity types have been considered.

In this article we try to give an exhaustive answer to this question for the isotropic and homogeneous Universe. To make it worse, in addition to unknown DE equation of state we have three possible signs of space curvature. We are interesting in the complete list of the possible types of future singularities for an arbitrary equation of state for three signs of space curvature. The possible singularity types for the flat Universe were considered in the paper [3], but we find a new one. We consider an arbitrary equation of state \( p(\rho) \) without any constrains except \( \rho \geq 0 \). In particular we do not use the strong energy condition \( \rho + 3p > 0 \).
II. THE SEARCH FOR FUTURE SINGULARITIES IN FLRW UNIVERSE

We consider the homogeneous isotropic Universe with the Friedmann-Lemaître-Robertson-Walker (FLRW) metric

\[ ds^2 = dt^2 - a(t)^2 \left[ d\chi^2 + F(\chi)d\Omega^2 \right], \]

where \( a(t) \) is the scale factor, \( d\Omega^2 = d\Theta^2 + \cos^2(\Theta)d\varphi^2 \) is the distance element on a unit sphere, \( F(\chi) = \sin(\chi) \) and \( k = 1 \) for the closed Universe, \( F(\chi) = \sinh(\chi) \) and \( k = -1 \) for the open one, and \( F(\chi) = \chi \) and \( k = 0 \) for the spatially flat models. We use the system of units in which \( G = 1 \) and \( c = 1 \). This Universe is filled by all kinds of matter and dark energy with a mass density \( \rho \) and an effective pressure \( p(\rho) \). In this system of units the energy density \( \varepsilon \) coincides with \( \rho \). The Einstein equations for the metric (2) reduce to the well-known Friedmann equations. We need the expression for the Hubble parameter

\[ H^2 = \frac{8\pi}{3} \rho - \frac{k}{a^2} \]

and the hydrodynamical equation or the energy conservation equation

\[ \frac{d\rho}{dt} = -3(\rho + p)H. \]

The Friedmann equation for the scale factor

\[ \frac{d^2a}{dt^2} = -\frac{4\pi}{3}a(\rho + 3p) \]

follows from the equations (3) and (4).

A. Flat model

We start from the flat model with \( k = 0 \). The equation (3) provides the expression \( H = (8\pi\rho/3)^{1/2} \). After substituting it into (4) we obtain a simple equation with the solution

\[ \Delta t = t_0 - t_1 = -\frac{1}{2(6\pi)^{1/2}} \int_{\rho_1}^{\rho(t)} \frac{dp}{\rho^{1/2}(\rho + p(p))}. \]

Here the subscript 1 corresponds to the initial parameters (i.e. \( t_1 \) is “now”) and the subscript 0 corresponds to the parameters of the Universe in the future at time \( t_0 \) after a time interval \( \Delta t \). We will denote the instant of time of any terminal cosmological singularity as \( t_0 \), and use (6) to analyse their properties. After finding the dependence \( \Delta t(\rho) \) we find the inverse function \( \rho(\Delta t) \) and \( H(\Delta t) \), the integration of the last one gives \( \ln(\alpha) \).

The first thing to check is the finiteness of \( \Delta t \). If the integral in (6) diverges we obtain \( t_0 = \infty \) and this case deals with the asymptotic evolution in the future. An example of such solution is the “Little Rip” [3].

We are going to go over all possible types of singularity. We consider three possible cases for \( \rho_0 \). It can be infinite, finite and nonzero, or equal to zero. Let us consider it one by one.

1. Infinite terminal density

Let us start with a well-known “Big Rip” singularity to illustrate our approach. We consider the equation of state (11). If \( w = -1 \) we deal with the effective cosmological constant. According to (11) in this case the density and the pressure are constant. If \( w > -1 \) the values of \( \rho \) and \( H \) decrease in time because of (11). If \( w < -1 \) the values of \( \rho \) and \( H \) increase due to (11) and become infinite at time \( t_0 \). Equation (6) gives us in this case the relations

\[ \rho_1 = \frac{1}{6\pi(1+w)^2\Delta t^2}, \quad H = \frac{2}{3(1+w)\Delta t}. \]

This is the so-called “Big Rip” case (1). The scale factor of the Universe diverges \( a \propto \Delta t^{-2/(1+w)} \).

A somewhat similar case is when \( w = -1 \) and this case

\[ \rho + p \propto -A\rho^\delta \]

with \( \alpha < 1 \), \( A = \text{const.} \). The integral in (6) is finite at 1/2 < \( \alpha < 1 \). In this case we have the “Big Rip” with \( H \propto \Delta t^{1/(1-2\alpha)} \), \( \ln a \propto \Delta t^{2(1-\alpha)/(1-2\alpha)} \). It occurs later and has a sharper shape for the same initial value \( \rho_1 \) in comparison with the equation of state (11).

If \( \alpha < 1/2 \) the integral in (6) becomes divergent and we have to put \( t_0 = \infty \). This is the so-called “Little Rip” introduced in [8]. In this case we rewrite (6) in the form

\[ \Delta t = t - t_1 = -\frac{1}{2(6\pi)^{1/2}} \int_{\rho_1}^{\rho(t)} \frac{dp}{\rho^{1/2}(\rho + p(p))}. \]

This case corresponds to an eternally accelerating expansion of the Universe: \( H \propto t^{1/(1-2\alpha)} \), \( \ln a \propto t^{2(1-\alpha)/(1-2\alpha)} \).

In the intermediate case \( \alpha = 1/2 \) we must take into account a possible logarithmic divergence and consider the equation of state with the asymptote \( \rho + p \propto -A\rho^{1/(2\ln(\rho))} \). At \( \beta > 1 \) we deal with the unconventional “Big Rip” with \( \ln a \propto \Delta t^{1/(1-\gamma)} \), at \( \beta < 1 \) we deal with the “Little Rip” with \( \ln a \propto t^{1/(1-\gamma)} \). At \( \beta = 1 \) we consider the equation of state with the asymptotic \( \rho + p \propto -A\rho^{1/(2\ln(\rho))} \). There is the “Big Rip” with \( \ln a \propto \Delta t^{1/(1-\gamma)} \) at \( \gamma < 1 \) and the “Little Rip” with \( \ln a \propto t^{1/(1-\gamma)} \) at \( \gamma > 1 \). If \( \gamma = 1 \) we can go on with this way and consider the asymptotic \( \rho + p \propto -A\rho^{1/(2\ln(\rho))} \), \( \ln a \propto t^{1/(2\ln(\rho))} \), etc. Similar results were obtained in [8].
So far we considered cases with \( a \xrightarrow{\rho \to \infty} \infty \), but this is not required. For example, a type III singularity, which was named “Big Freeze” in the paper [3], has finite \( t_0 \) and \( a_0 \) values, but \( \rho, H, |p| \xrightarrow{t \to t_0} \infty \). Let us consider this type of singularity. From \( H = a^{-1}da/dt \xrightarrow{t \to t_0} \infty \) and \( a(t) \xrightarrow{t \to t_0} a_0 \) we see that \( a(t) \) is regular, but \( da/dt \) diverges at \( t = t_0 \). This is possible if the scale factor has a power-law asymptote

\[
a(t) \xrightarrow{t \to t_0} a_0 - B(t_0 - t)^\lambda
\]

with \( 0 < \lambda < 1 \). This yields \( H \xrightarrow{t \to t_0} \lambda B(t_0 - t)^{\lambda - 1}/a_0 \). From [3] we obtain for this case \( \rho(t) \propto (t_0 - t)^{2(\lambda - 1)} \).

After substituting these expressions in [3] we get \( \rho(t) + p(t) \propto (t_0 - t)^{\lambda - 2} \). This corresponds to the equation of state [3] with \( \alpha = \frac{2 - \lambda}{2 - 2\lambda} \), \( \lambda = \frac{2 - \alpha}{2\lambda - 1} \). In this case \( \alpha > 1 \) and \( |p| \propto \rho^{\alpha} > \rho \) in the vicinity of the singularity.

Let us consider this type of singularity directly from [3]. If \( \rho \xrightarrow{t \to t_0} \infty \) but \( \rho/p \xrightarrow{\rho \to \infty} 0 \), e.g. \( p(t) \xrightarrow{\rho \to \infty} -\Lambda \rho^\alpha \) with \( \alpha > 1 \), \( A = \text{const} \) we also have a singularity with \( H \propto \Delta t^{1/(1 - 2\alpha)} \), \( a \propto \Delta t^{2/(1 - \alpha)/(1 - 2\alpha)} = t_0^{\lambda/2} \). Note that at \( \alpha < 1 \) we get the “Big Rip” case considered above.

But in the case of the “Big Freeze” singularity the scale factor tends to some constant value. Thus, we can study the “Big Freeze” either starting from the asymptotic behaviour of the equation of state [3] with \( \alpha > 1 \) or from the asymptote [10]. The asymptotic behaviour of the parameters of the Universe \( p(t)(t - t_0)\rho(t)^{-1} \xrightarrow{t \to t_0} \text{const} \) near the type III singularity follows from the above-mentioned asymptotes.

If we deal with the power law [10] for the scale factor with some noninteger \( \lambda > 1 \) we have no “Big Freeze” singularity, but some higher derivatives of \( H \) diverge. If \( 1 < \lambda < 2 \) both parts of the Friedmann equation [3] diverge, if \( \lambda > 2 \) both of them tend to zero. This case corresponds to \( \rho \xrightarrow{t \to t_0} 0 \), \( |p| \xrightarrow{t \to t_0} \infty \) and we will consider it later.

Is a version of the “Big Freeze” with \( t_0 = \infty \) possible? It could be named the “Little Freeze” similarly to the situation with the “Big Rip” and the “Little Rip”. In this case instead of [10] we consider an asymptotic behaviour of the scale factor in the form \( a(t) \xrightarrow{t \to \infty} a_0 - Bt^\lambda \) with \( \lambda < 0 \). According to [3] and [4] we have in this case \( \rho(t) \propto t^{2\lambda - 2} \xrightarrow{t \to \infty} 0 \) and \( p(t) \propto t^{\lambda - 2} \xrightarrow{t \to \infty} 0 \). This possibility will be considered later, too.

The only remaining singularity with infinite density is the well-known “Big Crunch” with \( H \to -\infty \), which we do not consider here.

2. Finite terminal density

Let us consider singularities with a nonsingular \( \rho \xrightarrow{t \to t_0} \rho_0 \neq 0 \). In this case all nontrivial solutions require \( p + \rho \) factor to diverge or vanish according to (3). In the first case \( |p| \to \infty \), the second one corresponds to the crossing the line \( \rho + p = 0 \). It corresponds to the equation of state of the cosmological constant, separating the phantom energy domain with an effective \( w < -1 \) from the domain of not so exotic matter \( w > -1 \). One can find in a literature both a statement that such a crossing is forbidden [10] and an example of a solution with such a crossing [11]. We will see that the possibility of such crossing depends on the parameters of the equation of state.

We start with considering solutions with finite \( t_0 \). Both cases could be described by a single power-law asymptote of the equation of state

\[
\rho + p(\rho) \xrightarrow{\rho \to \rho_0} C(\rho - \rho_0)^\mu
\]

with \( C = \text{const} \). At \( \mu < 0 \) the modulus of the pressure tends to infinity, at \( \mu > 0 \) the \( \rho + p \) reaches zero. The finiteness of \( t_0 \) is possible only at \( \mu < 1 \). In this case we have \( p(t) - \rho_0 \propto \Delta t^{1/(1 - \mu)} \), \( \rho(t) + p(t) \propto \Delta t^{\mu/(1 - \mu)} \). The singularity with \( \mu < 0 \) and \( |p| \xrightarrow{\rho \to \rho_0} \infty \) is referred to as the type II or sudden singularity. The value of \( H \) tends to finite \( H_0 \), so the scale factor linearly increases.

The achievement of \( \rho + p = 0 \) condition in finite time is possible if \( 0 < \mu < 1 \). Thus, the Universe can change the type of its equation of state from phantom energy to a more ordinary one, but only for such kind of the asymptote of the equation of state.

At \( \mu > 1 \) we obtain \( t_0 = \infty \), i.e. the asymptotic approximation of \( \rho + p = 0 \) condition. The evolution of such a Universe at the terminal stage practically coincides with the evolution of the flat Universe with a cosmological constant and without any other types of matter. There is no spacetime singularity in this case. Using the approximation [11] we obtain the asymptotes \( \rho(t) - \rho_0 \propto t^{\nu/(1 - \mu)} \), \( \rho(t) + p(t) \propto t^{\mu/(1 - \mu)} \) at \( t \to \infty \). This solution can mimic the ΛCDM model.

3. Zero terminal density

This last possibility assumes \( \rho_0 = H_0 = 0 \), which means that a scale factor tends to some extremum. But this does not mean an asymptotic expansion or contraction of the Universe is impossible. One simple example is the case \( \alpha \propto t^n \), \( 0 < \eta < 1 \) when the Universe keeps expanding, but \( H \) decreases and tends to zero.

Let us consider the power-law asymptote of the equation of state

\[
\rho + p \xrightarrow{\rho \to \rho_0} -D\rho^\eta
\]

and substitute it into [3]. The integral in [3] is finite at \( \nu < 1/2 \), which yields finite \( t_0 \). In this case \( \rho \propto \Delta t^{2/(1 - 2\nu)} \xrightarrow{t \to t_0} 0 \), \( H \propto \Delta t^{1/(1 - 2\nu)} \xrightarrow{t \to t_0} 0 \), \( \rho + p \xrightarrow{t \to t_0} 0 \).
If $0 < \mu < 1/2$, pressure tends to zero. This is a type IV singularity. If $\lambda = 1 + 1/(1 - 2\nu)$ is a noninteger number, the higher derivatives of $H \propto \Delta t^{\lambda - 1}$ diverge. The condition $0 < \mu < 1/2$ means $\lambda > 2$, so the first derivative of $H$ is finite, as well as both sides of the Friedmann equation (3). The value of $\lambda$ is the same as in (10). We can introduce the effective barotropic index $a \propto H \Delta t^{(2\nu - 2)/(1 - 2\nu)} \rightarrow \infty$. This singularity type was introduced in (12).

If $\mu < 0$ we have $|p| \rightarrow t \rightarrow \infty$. This is a new type of the future singularity, which we name “Big Squeeze”. It combines certain properties of the sudden singularity and the type IV singularity. It corresponds to $1 < \lambda < 2$ in (10). The first derivative of $H$ and both sides of the Friedmann equation (3) diverge. The asymptotics near this singularity type are $\rho \propto \Delta t^{(2\nu - 2)/(1 - 2\nu)} \rightarrow 0$, $H \propto \Delta t^{(2\nu - 2)/(1 - 2\nu)} \rightarrow 0$, $|p| \propto \Delta t^{(2\nu - 2)/(1 - 2\nu)} \rightarrow 0$, $a \rightarrow a_0 + \text{const} \Delta t^{(2\nu - 2)/(1 - 2\nu)} \rightarrow a_0$. It requires the equation of state (12) with negative $\nu$. The example is the generalized Chaplygin gas which occurs in some cosmological theories.

At $1/2 < \nu < 1$ the integral in (10) diverges and $t_0 = \infty$. In this case $\rho \propto t^{2(1/2 - \nu)}/(1 - 2\nu) \rightarrow 0$, $H \propto t^{1 - (1/2 - \nu)} \rightarrow 0$, $\rho + p \propto t^{2\nu - 2}/(1 - 2\nu) \rightarrow 0$, $a \rightarrow a_0 - Bt^{2/(2 - (1 - 2\nu))}$. This is the mentioned above solution which could be named the “Little Freeze”. In this case the effective barotropic index $w = p/\rho \propto t^{2/(2 - (1 - 2\nu))} \rightarrow \infty$.

At $\nu = 1/2$ we can take into account the possible logarithmic factor and consider the asymptotic equation of state $\rho + p \rightarrow -Dp^{1/2} = (\ln \rho)^{\beta}$. At $\beta > 1$ we deal with the unconventional type IV singularity with $\ln \rho \propto \Delta t^{1/(1 - \beta)}$, at $\beta < 1$ we deal with the “Little Freeze” with $\ln \rho \propto t^{1/(1 - \beta)}$. At $\beta = 1$ we consider the equation of state with the asymptotic $\rho + p \rightarrow -Dp^{1/2} = (\ln \rho)^{\beta}$, etc.

At $\nu > 1$ we deal with the expanding Universe and $\ln a \propto t^{2/(2 - (2\nu - 1))} \rightarrow \infty$ at $D > 0$ in spite of $H \propto t^{1/(1 - 2\nu)} \rightarrow 0$. This is the new “Little Freeze” case. The higher derivatives of $H$ diverge. At $\nu = 1$ the Universe expands according to power law $a \propto t^{2/3D}$. The effective barotropic index $w = p/\rho \rightarrow -1$. Note that all version of the “Little Freeze” differ from the so-called pseudo-rip, which also corresponds to $t_0 = \infty$ (13).

B. Open and closed models

We went over the possible singularities for the case of the flat Universe and an arbitrary equation of state of its content. Let us study the cases of open ($k = -1$) and closed ($k = 1$) Universes. The second term in the right-hand side of (3) does not affects the properties of the singularities with $\rho, H \rightarrow 0$ and $\rho \rightarrow \rho_0 \neq 0, H \rightarrow H_0 \neq 0$. The only exception is the “Big Crunch” singularity with $a \rightarrow 0$ which we do not study in this paper.

But we must revise a possibility of the existence and the properties of singularities with $H \rightarrow 0$ or $\rho \rightarrow 0$. We use the asymptotic equation of state (12). All solutions with $\rho \rightarrow 0$ are impossible because the equation (3) cannot be satisfied. But the solutions with $a \rightarrow 0$ can remain practically the same as in the flat case. The matter with the asymptotic equation of state (12) with $\nu > 1$ is a good example of this case. The term $ka^{-2}$ is much less than the practically equal terms $H^2$ and $8\pi\rho/3$. At $\nu = 1$ i.e. $a \rightarrow a_0 \rightarrow \infty$ the term $ka^{-2}$ is much smaller than the other ones in (3) at $t \rightarrow \infty$ in the case $D > 3/2$, i.e. $w < -5/2$.

In the case $\nu < 1$ we must compare the main terms in (3). The case $H^2 \rho \gg a^{-2}$ is impossible. The case $k = -1$, $H^2 \approx a^{-2} \gg \rho$ leads to $a \rightarrow 0$. This is the metric of the flat space-time and the coordinate transformation $r = t\sinh \xi, \tau = t\cosh \xi$ turns it into the Minkowski metric. Naturally, this space-time is empty, $\rho = 0$. However this is an unstable solution. Considering some infinitesimal mass density $\rho$ we get at $t \rightarrow \infty$ the asymptotic equation $dp/dt = D\rho^{\nu}$ with the solution $\rho = (3D(1 - \nu)\ln t + \text{const})^{1/(1 - \nu)}$. $\rho$ diverges and the term with it becomes the main one in (3) at $t \rightarrow \infty$. The case $k = 1$, $8\pi\rho/3 \approx a^{-2} \gg H^2$ leads to $|da/dt| \ll 1$, $\rho \ll a^{-2}$. These conditions exclude all known types of future singularities. Moreover, the last condition gives us $dp/dt = -2pH$. After substituting it into (3) we get $H(3D\rho^{\nu} - 2\rho) = 0$. This is possible if $H = 0$ (the Einstein’s static Universe) or $\rho = 0$ (the empty Universe without DE) or $\nu = 1, D = -2/3$. The last case means that $p = -\rho/3$. In all these cases we have no new type of singularity.

The last possibility is the case in which all terms in (3) are of the same order of magnitude. It gives us no solutions except the “Big Crunch”. Thus, the equation of state (12) with $\nu < 1$ could provide the type IV or the “Big Squeeze” singularities only for the flat model. There are no types of singularities specific for open or flat model.

III. CONCLUSION

We went over the possible types of future singularities for an arbitrary equation of state of the Universe with power-law asymptotes and found all the known types plus the new “Big Squeeze” and “Little Freeze” ones. We do not indicate all particular subtypes like “the little sibling of the Big Rip singularity” (14), but find all the asymptotes for the scale factor, density and pressure in the vicinity of the main singularity types. We follow a unified approach. For the simplest flat model it reduces to the ordinary integral (3) for finite cosmological time of singularity or (9) for infinite one.

We tabulate all main cases of the cosmological singu-
The asymptote of the equation of state at \( \rho \rightarrow \infty \) are possible only for the flat Universe. The asymptote of the terminal density, pressure, and scale factor remain the same. So, the list of singularity types is exhaustive.
