Introduction

The nail gun has useful industrial applications. Increasing use of the nail gun has led to higher injury rates from the use of tools with sequential actuation. Nail gun injury can occur to various parts of the body. Very deep penetration in the brain can have fatal results. A 46-year-old male fired shots from a nail gun into his brain in a suicide attempt. This case demonstrated successful surgical management of the resultant open head injury.

Case Report

A 46-year-old male presented to our hospital with a Glasgow coma scale score of 3 and an open head injury. His son found him at home in possession of a nail gun. The patient was in a drunken state. Neurological examination revealed grade 0 motor reflexes; light pupillary reflex: 3 mm fix/5 mm fix and a comatose mental state. The scalp was ripped by the nail and the brain was exposed.

Brain computed tomography (CT) revealed comminuted fracture of the left temporal bone with inward displacement of bony fragments and foreign body in the suprasellar cistern to the right medial temporal lobe, with intracranial hemorrhage in the left temporal lobe along the moving pathway of the foreign body (Figure 1). His vital signs were very unstable, and required orotracheal intubation with mechanical ventilator application. The patient was transferred to the intensive care unit, after initiation of antibiotic therapy. Surgery was planned for the removal of the penetrated nail, after the vital signs were stabilized. Preoperative CT angiography revealed no gross evidence of vascular injury (Figure 2).

General anesthesia was employed. The patient was positioned supine with the head turned to the right on a horsehoe-shaped head holder. Intra-operatively, we found burned scalp (1st degree) and torn dura. We removed multiple fragmented temporal bony fragments. We attempted cerebral endoscopy for removal of the nail, after bleeding control. However, continuous minimal bleeding blocked the operative sight. The nail was found by stylet with assisted neuronavigation (Medtronic StealthStation® S7™, Louisville, CO, USA) and removed with forceps (Figure 3). A drainage catheter of intracerebral hematoma was placed and dural closure was accomplished with Durafoam® (Codman, Wokingham, UK). Greenplast™ (Greencross, Seoul, Korea) were applied to prevent cerebrospinal fluid leakage.

The patient’s vital signs stabilized after removal of the nail. Neurological examination revealed Grade 3 motor reflexes; light pupillary reflex: 6 mm fix/6 mm fix; and a semi-
Open Head Injury by Nail Gun

Comatose mental state. Hydrocephalus had developed a month later. After ventriculoperitoneal shunt operation (Figure 4), neurological examination revealed Grade 3 motor reflexes; light pupillary reflex: 5 mm fix/5 mm fix; and stuporous mental state with a Glasgow coma scale score of 6.

Discussion

Injury rates have increased with the wide use of the nail-gun. The most common cause of nail-gun injury is work-related accidents, although there are some instances of suicide. The efforts to reduce accidents is successful, however it is difficult to reduce nail gun use for suicidal purposes. Additionally, resultant brain injury can be fatal, and treatment is aimed at survival. We have three things considered for the treatment of patient. First, as in an emergency situation, airway, respiration and circulation are required to be evaluated. Our patient had acidosis and hypotension due to respiratory failure. Our patient’s vital sign was stable after orotracheal intubation and mechanical ventilation. Second, the most commonly reported complications are the development of meningitis and cerebral abscesses. So third generation cephalosporins (Triaxone, 2 gm/day) used immediately in this case. Third, the nail is required to be removed safely. So our patient’s nail was found by stylet with assisted neuronavigation (Medtronic StealthStation® S7™) and removed with forceps. But if we can use electromagnetic tools, we enable more safe and easy removal.

Many patients with intracranial nail injuries survive with
a relatively good neurological outcome, as long as the great cerebral vessels are intact and the brainstem is spared. But prognosis was poor when primary traumatic brain stem damaged. In this case, major blood vessels were intact, but due to early brain stem damage clinical outcome was poor.

**Conclusion**

The nail gun is a powerful industrial tool used to drive nails into various hard surfaces with ease. However, there is an increased risk of injury to humans. If penetration is very deep in the brain, the results may be fatal. This case demonstrated successful surgical management of open head injury resulting from a nail gun. Brain stem injury in the subject led to a poor prognosis.
