Recent CDF and DØ measurements of the top quark forward-backward asymmetry at the Tevatron present deviations between 1σ and 2σ from QCD predictions and a cut $M_{t\bar{t}} > 450$ GeV on the events increases this deviation to 3.4 σ in the CDF measurement. The inclusion of electroweak contributions of $\mathcal{O}(\alpha^2)$ and $\mathcal{O}(\alpha\alpha_s^2)$ enlarges the theoretical prediction from QCD by a factor $\sim 1.2$ and diminishes the observed deviations. The calculation method is shortly discussed and numerical results are compared to the experimental data.
1. Introduction

In the experimental analyses at the Tevatron, two different definitions of the forward-backward asymmetry have been used:

\[ A_{FB}^{til} = \frac{\sigma(\Delta y > 0) - \sigma(\Delta y < 0)}{\sigma(\Delta y > 0) + \sigma(\Delta y < 0)} \] (1.1)

and

\[ A_{FB}^{pp} = \frac{\sigma(y_t > 0) - \sigma(y_t < 0)}{\sigma(y_t > 0) + \sigma(y_t < 0)} \] (1.2)

where \(\Delta y\) is defined as the difference between the rapidity \(y_t\) and \(y\) of the top quark and \(\bar{t}\) and the beam axis is oriented in the direction of the proton. The values obtained by CDF for the inclusive asymmetry \([4]\) are \(A_{FB}^{til} = 0.158 \pm 0.075\), \(A_{FB}^{pp} = 0.150 \pm 0.055\). \(A_{FB}^{til}\) is compatible with the value obtained by D0 \(A_{FB}^{til} = 0.196 \pm 0.065\) \([2]\).

All these values are larger than the Standard Model LO predictions \(A_{FB}^{til} \sim 7\%\), \(A_{FB}^{pp} \sim 5\%\) (see e.g. \([3]\)) and imposing a cut \(M_{tt} > 450\) GeV, the value obtained by CDF \(A_{FB}^{til} = 0.475 \pm 0.114\) is at 3.4 \(\sigma\) from the prediction at this level of accuracy. These results have led to many speculations on the presence of new physics and so a thorough discussion of the SM prediction and the corresponding uncertainty is necessary. At present, the theoretical accuracy is limited by the missing calculation of the complete NNLO contribution from QCD to the antisymmetric part of the \(t\bar{t}\) production cross section. Besides the strong interaction, also the electroweak interaction gives rise to contributions to the \(t\bar{t}\) forward-backward asymmetry. Although smaller in size, they are not negligible, and a careful investigation is an essential ingredient for an improved theoretical prediction.

In the following we briefly summarize our calculation and compare numerical results with experimental data. This talk is based essentially on \([2]\).

2. Outline of the calculation

Tree level diagrams of the partonic subprocesses are gluon, photon ad Z s-channel type for \(q\bar{q} \rightarrow t\bar{t}\) (Higgs exchange is completely negligible) and s-channel, t-channel and u-channel type for \(gg \rightarrow t\bar{t}\). At leading order the production of \(t\bar{t}\) pairs in \(p\bar{p}\) collisions originates, via the strong interaction, from the partonic processes \(q\bar{q} \rightarrow g \rightarrow t\bar{t}\) and \(gg \rightarrow t\bar{t}\), which yield the \(\mathcal{O}(\alpha_s^2)\) of the (integrated) cross section, i.e. the denominator of \(A_{FB}\) in \([1.1]\) and \([1.2]\). Instead the antisymmetric cross section, the numerator of \(A_{FB}\), starts only at \(\mathcal{O}(\alpha_s^3)\), so the leading term of the asymmetry involves one loop corrections to \(t\bar{t}\) pair production.

Writing the numerator and the denominator of \(A_{FB}\) (for either of the definitions \([1.1]\) and \([1.2]\)) in powers of \(\alpha_s\) and \(\alpha\) we obtain

\[ A_{FB} = \frac{N}{D} = \frac{\alpha^2 \tilde{N}_0 + \alpha^3 N_1 + \alpha^4 N_2 + \cdots}{\alpha^2 D_0 + \alpha^2 D_0 + \alpha^2 D_1 + \alpha^2 \alpha D_1 + \cdots} = \alpha_s \frac{\tilde{N}_1}{D_0} + \alpha_s^2 \frac{N_2 - N_1 D_1/D_0}{D_0} + \alpha_s \frac{\tilde{N}_0}{D_0} + \alpha_s^2 \frac{\tilde{N}_0}{D_0} + \cdots \] (2.1)

Only some parts of \(N_2\) are currently known \([2, 4]\) and the inclusion of the \(N_1 D_1/D_0\) term without \(N_2\) would be incomplete, so we have chosen to drop the incomplete \(\mathcal{O}(\alpha_s^2)\) part, as done in \([4]\).
The squared terms \(|M_{qg}\rangle^2|\) and \(|M_{gg}\rangle^2|\) yield \(D_0\) of the LO cross section; the \(O(\alpha^2)\) terms arise from \(|M_{qg\gamma}\rangle^2| + |M_{qgZ}\rangle^2|^2\), which generate a purely-electroweak antisymmetric differential cross section, in the parton cms given by

\[
\frac{d\sigma_{\text{asym}}}{d\cos\theta} = 2\pi\alpha^2 \cos\theta \left( 1 - \frac{4m_t^2}{s} \right) \left[ \kappa \frac{Q_qQ_Aq_At}{(s-M_Z^2)} + 2\kappa^2 A_qA_t V_qV_t \frac{s}{(s-M_Z^2)^2} \right],
\]

where \(\theta\) is the top-quark scattering angle, \(Q_q\) and \(Q_t\) are the charges of the parton \(q\) and of the top and \(A_q, A_t\) and \(V_q, V_t\) are their axial and vectorial couplings to the Z boson. In \(A_{FB}\) this leads to the term \(\tilde{N}_0\). The complementary symmetric cross section provides the term \(\tilde{D}_0\) in the denominator, which does not contribute in the order under consideration. Interferences of \(q\bar{q} \to \gamma Z \to t\bar{t}\) and \(q\bar{q} \to g g \to t\bar{t}\) are zero because of the color structure. Basically for \(q\bar{q} \to t\bar{t}\) there are also \(O(\alpha)\) \(W\)-mediated \(t\)-channel diagrams with \(q = d, s, b\), but they are strongly suppressed by the CKM matrix or by parton distributions \((q = b)\).

The \(O(\alpha^3)\) terms that contribute to \(N\) arise from four classes of partonic processes: \(q\bar{q} \to t\bar{t}, q\bar{q} \to t\bar{t}g, qg \to t\bar{t}q\) and \(q\bar{g} \to t\bar{t}g\). In the first case the origin is the interference of QCD one-loop boxes and Born amplitudes; the other processes correspond to real-particle emissions. The box integrals are free of ultraviolet and collinear divergences, but they involve infrared singularities which are cancelled after adding the integrated interference of initial and final state gluon radiation, the only asymmetric contribution from \(q\bar{q} \to t\bar{t}g\) at \(O(\alpha^3)\). \(qg \to t\bar{t}q\) and \(q\bar{g} \to t\bar{t}\bar{g}\) yield also contributions to \(A_{FB}\), but they are numerically not important.

In order to analyze the electroweak \(O(\alpha^2\alpha)\) terms, it is useful to separate the QED contributions involving photons from the weak contributions with \(Z\) bosons. In the QED sector we obtain the \(O(\alpha^2\alpha)\) contributions to \(N\) from these three classes of partonic processes: \(q\bar{q} \to t\bar{t}, q\bar{q} \to t\bar{t}g\) and \(q\bar{g} \to t\bar{t}\gamma\). The first case is the virtual-photon contribution, which can be obtained from the QCD analogue, namely the \(O(\alpha^3)\) interference of box and tree-level amplitudes, by substituting successively each one of the three internal gluons by a photon, as displayed in Figure [2].

In a similar way, also the real-radiation processes \(q\bar{q} \to t\bar{t}g\) and \(q\bar{g} \to t\bar{t}\gamma\) can be evaluated starting from the result obtained for \(q\bar{q} \to t\bar{t}g\) in the QCD case and substituting successively each gluon by a photon.

The antisymmetric \(O(\alpha^3)\) term from \(q\bar{g} \to t\bar{t}g\) comes from the interference of \(q\bar{g} \to g \to t\bar{t}g\) and \(q\bar{g} \to g \to t\bar{t}g\), while in the case of \(q\bar{q} \to t\bar{t}\gamma\) it comes from the squared amplitude obtained from \(q\bar{g} \to g \to t\bar{t}\gamma\) diagrams. The essential differences between the calculation of the \(O(\alpha^3)\) and of

\[1\text{In a very recent paper [3] the expansion of } A_{FB} \text{ in powers of } \alpha_3 \text{ has been revisited applying the principle of maximum conformality. In this case } N_2 \text{ and also } D_2 \text{ seems to be numerically negligible, so the term } N_1 D_1/D_0 \text{ can be safely included.} \]
Figure 1: Different ways of QED–QCD interference at $\mathcal{O}(\alpha^2 s \alpha)$.

QED $\mathcal{O}(\alpha^2 s \alpha)$ terms are only the coupling constants and the appearance of the $SU(3)$ generators in the strong vertices. Summing over color in the final state and averaging in the initial state, we find that we can relate the QED contribution of the antisymmetric term $\tilde{N}_1$ in (2.1) to the $\mathcal{O}(\alpha^3 s \alpha)$ QCD term $N_1$ for a given quark species $q \bar{q} \rightarrow t \bar{t}(+X)$ in the following way,

$$R_{\text{QED}}(Q_q) = \frac{\alpha \tilde{N}_1^{\text{QED}}}{\alpha s N_1} = Q_q Q_{\bar{t}} \frac{36}{5} \frac{\alpha}{\alpha_s}.$$  \hspace{1cm} (2.3)$$

Now we consider the weak contribution to $\tilde{N}_1$. It can be depicted by the same diagrams as for $q \bar{q} \rightarrow t \bar{t}$ and $q \bar{q} \rightarrow t \bar{t}g$ in the QED case, but with the photon now substituted by a $Z$ boson, involving massive box diagrams. The result cannot be expressed immediately in a simple factorized way. We performed the explicit calculation including also the contribution from real gluon radiation with numerical integration over the hard gluon part.

Also $Z$-boson radiation, $q \bar{q} \rightarrow t \bar{t}Z$, can contribute at the same order, but it yields only a tiny effect of $10^{-5}$ in $A_{FB}$ and thus may be safely neglected. The same applies to $u \bar{d} \rightarrow t \bar{t}W^\pm$ as well as to Higgs-boson radiation.

It is important to note that all these partonic subprocesses $p_1 p_2 \rightarrow t \bar{t}(+X)$ can be generated with $p_1 (p_2)$ coming from the first(second) hadron $h_1 (h_2)$ or from $h_2 (h_1)$. Given a kinematic configuration of $p_1 p_2 \rightarrow t \bar{t}(+X)$, if it contributes to $\sigma(Y_t > 0)$ in the $h_1 (h_2)$ configuration it contributes with the same partonic weight also to $\sigma(Y_t < 0)$ in the $h_2 (h_1)$ configuration. So the total contribution to $A_{FB}$ is non vanishing only if the weights coming from the parton distributions are different, that is if:

$$f_{p_1, h_1} (x_1) f_{p_2, h_2} (x_2) \neq f_{p_1, h_2} (x_1) f_{p_2, h_1} (x_2) \hspace{1cm} (2.4)$$

where $f_{p_i, h_j} (x_i)$ is the parton distribution of the parton $p_i$ in the hadron $h_j$. The same argument applies also to $A_{FB}$. At the LHC $h_1 = h_2$ so $A_{FB}$, using definitions (1.1) and (1.2), is equal to zero, at Tevatron (2.4) is not generally true but it can be used to distinguish which subprocesses can give rise to contribution to $A_{FB}$. Only initial states with at least one of the two $p_1$ and $p_2$ equal to (anti)quark up or (anti)quark down can produce an asymmetric contribution. This last statement is completely independent on
the assumptions made for the partonic calculation, it relies only on the way proton structure is described by partonic distribution functions.

3. Numerical results

According to the argument discussed after (2.1), we choose MRST2004QED parton distributions for NLO calculations and MRST2001LO for LO, using thereby $\alpha_s(\mu)$ of MRST2004QED also for the evaluation of the cross sections at LO (a similar strategy was employed in [3]). We used the same value $\mu$ for the factorization scale and we present the numerical results with three different choices for the scale: $\mu = m_t/2, m_t, 2m_t$. Other input parameters are taken from [9].

The various contributions to the asymmetry of either of the two variants $A_{FB}^{q}$ and $A_{FB}^{pb}$ are listed in Table 1. The ratio of the total $\mathcal{O}(\alpha_s^2\alpha) + \mathcal{O}(\alpha^2)$ and $\mathcal{O}(\alpha_s^3)$ contributions to the numerator $N$ of the asymmetry (2.1) gives an illustration of the impact of the electroweak relative to the QCD asymmetry. The values obtained for $\mu = (m_t/2, m_t, 2m_t)$ for the two definitions of $A_{FB}$ are

\[
R_{EW}^{q} = \frac{N_{q}^{q} \mathcal{O}(\alpha_s^2\alpha) + \mathcal{O}(\alpha^2)}{N_{q}^{q} \mathcal{O}(\alpha_s^3)} = (0.190, 0.220, 0.254),
\]

\[
R_{EW}^{pb} = \frac{N_{pb}^{pb} \mathcal{O}(\alpha_s^2\alpha) + \mathcal{O}(\alpha^2)}{N_{pb}^{pb} \mathcal{O}(\alpha_s^3)} = (0.186, 0.218, 0.243). \tag{3.1}
\]

This shows that the electroweak contribution provides a non-negligible additional part to the QCD-based antisymmetric cross section with the same overall sign. Thus it enlarges the Standard Model prediction for the asymmetry (the electroweak $\mathcal{O}(\alpha_s^2\alpha)$ contribution of $u\bar{u} \to t\bar{t}$ to the asymmetry is even bigger than the $\mathcal{O}(\alpha^3)$ contribution of $d\bar{d} \to t\bar{t}$).

The recent reevaluation of the mixed EW–QCD contribution to $A_{FB}$ in [10] presented values in agreement with our results.

The final result for the two definitions of $A_{FB}$ can be summarized as follows,

\[
A_{FB}^{q} = (9.7, 8.9, 8.3)\%, \quad A_{FB}^{pb} = (6.4, 5.9, 5.4)\%. \tag{3.2}
\]
Figure 2 displays the theoretical prediction versus the experimental data. The SM prediction is almost inside the experimental $1\sigma$ range for $A_{FB}^{t\bar{t}}$ and inside the $2\sigma$ range for $A_{FB}^{p\bar{p}}$. It is important to note that the band indicates the scale variation of the prediction, it does not account for all the theoretical uncertainties. For example, as already noted, the $O(\alpha^4)$ term in $N$ is missing, and we did not include the $O(\alpha^3)$ part in $D$. The decrement by about 30% obtained by the inclusion of this term can be considered, in a conservative spirit, as an uncertainty from the incomplete NLO calculation for the asymmetry.

Figure 2: Theoretical prediction (blue) and CDF data (black=central value, orange=$1\sigma$, yellow=$2\sigma$).

We have performed our analysis also applying a cut $M_{t\bar{t}} > 450$ GeV to the $t\bar{t}$ invariant mass. The various contributions to the asymmetry $A_{FB}^{t\bar{t}}$, as discussed above in the case without cuts, are listed for $M_{t\bar{t}} > 450$ GeV in the Table 2.

The asymmetry with cuts yields

$$A_{FB}^{t\bar{t}}(M_{t\bar{t}} > 450\text{ GeV}) = (13.9, 12.8, 11.9).$$  \hspace{1cm} (3.3)
A comparison between Table 2(a) and Table 1(a) shows that the ratio of the QCD contribution to the $u\bar{u} \rightarrow t\bar{t}$ and $d\bar{d} \rightarrow t\bar{t}$ subprocesses is larger with a $M_{tt} > 450$ GeV cut, which leads to a slight increase of $R_{EW}^{t\bar{t}}$:

$$R_{EW}^{t\bar{t}}(M_{tt} > 450 \text{ GeV}) = (0.200, 0.232, 0.266).$$  \hfill (3.4)

These values of $R_{EW}^{t\bar{t}}$, however, are not enough to improve the situation, indeed the Standard Model prediction is at the $3\sigma$ boundary in case of invariant-mass cut $M_{tt} > 450$ GeV (see Figure 3). In Figure 4, the comparison between theoretical prediction and experimental data from DØ is shown. The deviation is larger than in the CDF case (Figure 2(a)), but it is important to stress that no statistically significant enhancements have been found by DØ for the region according to the cut $M_{tt} > 450$ GeV.

4. Conclusions

The uncertainty of the theoretical prediction for the top quark forward-backward asymmetry at the Tevatron is dominated by the incomplete calculation of the contribution from NNLO QCD corrections to the antisymmetric cross-section. The electroweak contribution is not negligible and increases the LO prediction by a factor $\sim 1.2$, with differences due to the specific definition of the asymmetry and the choice of the renormalization scale. The main part of these corrections is from QED origin and it can be derived from the LO contribution multiplied by a simple factor depending on the charge of the incoming partons.

Electroweak corrections cannot explain the enhancement found by CDF including a cut $M_{tt} > 450$ GeV, but they must not be neglected when the deviation is interpreted as presence of new physics.
Figure 4: Theoretical prediction (blue) and DØ data (black=central value, orange=1σ, yellow=2σ).
