Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Coronavirus 2019 (COVID-19), caused by the pathogen SARS-CoV-2, was declared a pandemic in March 2020. Recently, studies have discussed reports of patients infected with COVID-19 associated with vesicular manifestations of Herpes Zoster. The objective of this study was to compare the data from the Unified Health System (SUS) on the number of diagnoses of Herpes Zoster from March to August from 2017 to 2019, with the same period in 2020, in the five Brazilian regions (North, Northeast, Southeast, South, and Midwest). The data were extracted from the public database (DATASUS) of Brazil’s Ministry of Health. The data showed an increase in the number of Herpes Zoster diagnoses over the years and the negative impact from the COVID-19 disease, revealing an average increase corresponding to an extra 10.7 cases per million inhabitants during the pandemic in all Brazilian Regions. Therefore, although the association between HZ and COVID-19 is not well established, we observed in this study an increase in HZ cases during the COVID-19 pandemic, which suggests a correlation between these diseases.

Coronavirus 2019 (COVID-19), caused by the pathogen SARS-CoV-2, was declared a pandemic by the World Health Organization (WHO) in March 2020 (Recalcati, 2020). Studies have discussed reports of patients infected with COVID-19 associated with vesicular manifestations of Herpes Zoster (HZ) (Fernandez-Nieto et al., 2020; Llamas-Velasco et al., 2020; Marzano et al., 2020; Ortega-Quijano et al., 2020; Recalcati, 2020). Recalcati (2020) reported for the first time the involvement of skin manifestations with the COVID-19 infection.

Varicella and Herpes Zoster are diseases caused by the Varicella-zoster virus (VZV) (Elsaei and Nada, 2020), which in its initial phase causes chickenpox (“Chickenpox”). This virus remains latent within the dorsal root of the trigeminal ganglion, and after its reactivation, it manifests itself as HZ (Elsaei and Nada, 2020). The objective of this study was to compare the data from the Unified Health System (SUS) on the number of diagnoses of Herpes Zoster from March to August 2017–2019, with the same period of 2020, in the five Brazilian regions (North, Northeast, Southeast, South, and Midwest).

The analyzed data were extracted from the public database (DATASUS) (http://tabelnet.datasus.gov.br/cgi/tabcgi.exe?siaria/cnv/qauf.def) of Brazil’s Ministry of Health (Anon, 2020a). Table 1 shows an increase in the number of HZ diagnoses over the years, and Table 2 shows the negative impact of the COVID-19 disease, revealing an increase in the number of HZ diagnoses in all Brazilian Regions. Descriptive analysis showed that the percentage of new HZ cases per million inhabitants has increased in all Brazilian regions, ranging from +23.6% in the Northwest to +77.2% in Midwest Region. The overall Brazilian average increase reached +35.4%, corresponding to an average increase of over 10.7 cases per million inhabitants during the COVID-19 pandemic.

The association between HZ and COVID-19 is unknown to date, but an increase in HZ infections during the COVID-19 outbreak has been observed (Llamas-Velasco et al., 2020). The COVID-19 infection can cause changes in leukocyte levels, resulting in a decrease in cell count, mainly of CD4+ T cells, CD8+ T cells, B cells, and natural killer cells (Tartari et al., 2020). The interference of
SARS–COV-2 in the dysregulation of the immune system associated with physical and mental stress may be one factor involved in the reactivation of VZV (Pona et al., 2020). In the presence of vesicular lesions, we emphasize the importance of HZ diagnoses through Tzanck smear, PCR test from vesicular fluid, or skin biopsy to exclude any infection by other viruses (Llamas-Velasco et al., 2020).

Regarding COVID-19 in Brazil, the updated data on 01/02/2021 from the Brazilian Ministry of Health, Coronavirus//BRAZIL (https://covid.saude.gov.br/COVID-19) (Coronavirus//BRASIL, n.d.) (Anon, 2020b) reported a total of 9,204,731 confirmed cases; 8,027,042 recovered cases; 224,504 confirmed deaths; incidence/100 thousand inhabitants: 43,801; mortality/100 thousand inhabitants: 106.8. One of the limitations of this study, we should mention cases not reported to the Brazilian public health system, which suggests that the actual incidence could be higher.

Therefore, although the association between HZ and COVID-19 is not well established, we observed in this study an increase in HZ cases during the COVID-19 pandemic, which suggests a correlation between these diseases. Controlled clinical studies are necessary to clarify whether this relationship is causal or circumstantial.
