INTRODUCTION

According to the World Health Organization nearly 450 million people suffering from psychological or behavioural ailments, yet only a small minority of them receive even the most elementary treatment. This amounts to 12.3% of the global load of disease and will rise to 15% by 2020 [1]. In the search for new therapeutic products for the treatment of neurological disorders, medicinal plant research has progressed constantly representing the pharmacological actions like dysentery and menorrhagia, and as a diuretic. Presently the most commonly approved medications for anxiety disorders are benzodiazepines but their clinical applications as antianxiety agents are limited due to their undesirable effects. Therefore the development of new pharmacological agents from plant sources are well justified.

Desmostachya bipinnata, commonly known in english as half a grass, big cordgrass, and salt reed-grass is an old world perennial grass, used in human history. In India, it is known as Doabh, Darbha, Kusha. From literature survey it was found that Desmostachya bipinnata processes antibacterial activity [3] anti-ulcerogenic [4], antioxidant and DNA damage protection activity [5], anti-histaminic activity [6], anti-obesity activity [7], glycemic Status in Non-diabetic Rats [8], diuretic and laxative activity [9], anti-diarrheal activity [10], anti urolithiatic activity [11], anti-helicobacter activity [12], use in gut disorders and asthma [13], analgesic and anti-inflammatory [14], hepatoprotective activity [15, 16]. The purpose of the present study was to evaluate the antianxiety activity of alcoholic and aqueous extracts of Desmostachya bipinnata leaves in rodents.

MATERIALS AND METHODS

Animals

Wistar rats (180±20g) of either sex were procured from institutional animal house and they were retained in the groups of six under the standard laboratory conditions (Temp 23±2 °C, relative humidity 50-60% and 12:12 h light–dark cycle), with standard pellet diet (Amrut brand) and water ad libitum. Experiments were performed only after the animals had acclimated to the laboratory conditions for at least seven days. The experimental protocol was approved by institutional animal ethics committee (1757/PO/RcbBt/CPCSEA).

Plant material collection and extraction

The leaves of Desmostachya Bipinnata were collected cleaned, reduced to small fragments, air dried under shade at room temperature and coarsely powdered in a mixer. The powdered material was taken up for alcoholic extraction by taking 250 ml beaker containing 200 ml of alcohol. The contents were mixed well and boiled up to 50-60 °C for 4-5 h. Further, the extract was filtered with whatmann filter paper. The filtrate was boiled until the concentrated residue is formed. The aqueous extract was prepared by taking 20 gms of finely cut leaves into 250 ml beaker containing 200 ml of water and was boiled up to 80-100 °C for 4-5 h. Further, the extract was filtered with whatmann filter paper. The filtrate was boiled until the concentrated residue is formed.

Results: The results infer that reduced aversion fear elicits anti-anxiety activity.

Conclusion: It was concluded that alcoholic and aqueous extracts of Desmostachya bipinnata leaves are having anti-anxiety activity among which alcoholic extract of Desmostachya bipinnata leaves showing more significant activity over the aqueous extract.

Methods: Antianxiety activity was screened by different methods like elevated plus maze model and actophotometer.

ABSTRACT

Objective: Anxiety is a widespread psychiatric disorder affecting around 5% of the population. Furthermore, it is difficult to predict patient’s response to any given treatment. In the traditional systems of medicine, many plants have been used to treat anxiety and depression for thousands of years. Desmostachya bipinnata belongs to the family Poaceae, have pharmacological actions like dysentery and menorrhagia, and as a diuretic. The present study was designed to evaluate the antianxiety activity of the alcoholic and aqueous extracts of Desmostachya bipinnata leaves in rodents.

Methods: Antianxiety activity was screened by different methods like elevated plus maze model and actophotometer.

Results: The results infer that reduced aversion fear elicits anti-anxiety activity.

Conclusion: It was concluded that alcoholic and aqueous extracts of Desmostachya bipinnata leaves are having anti-anxiety activity among which alcoholic extract of Desmostachya bipinnata leaves showing more significant activity over the aqueous extract.

INTRODUCTION

According to the World Health Organization nearly 450 million people suffering from psychological or behavioural ailments, yet only a small minority of them receive even the most elementary treatment. This amounts to 12.3% of the global load of disease and will rise to 15% by 2020 [1]. In the search for new therapeutic products for the treatment of neurological disorders, medicinal plant research has progressed constantly representing the pharmacological actions like dysentery and menorrhagia, and as a diuretic. Presently the most commonly approved medications for anxiety disorders are benzodiazepines but their clinical applications as antianxiety agents are limited due to their undesirable effects. Therefore the development of new pharmacological agents from plant sources are well justified.

Desmostachya bipinnata, commonly known in english as half a grass, big cordgrass, and salt reed-grass is an old world perennial grass, used in human history. In India, it is known as Doabh, Darbha, Kusha. From literature survey it was found that Desmostachya bipinnata processes antibacterial activity [3] anti-ulcerogenic [4], antioxidant and DNA damage protection activity [5], anti-histaminic activity [6], anti-obesity activity [7], glycemic Status in Non-diabetic Rats [8], diuretic and laxative activity [9], anti-diarrheal activity [10], anti urolithiatic activity [11], anti-helicobacter activity [12], use in gut disorders and asthma [13], analgesic and anti-inflammatory [14], hepatoprotective activity [15, 16]. The purpose of the present study was to evaluate the antianxiety activity of alcoholic and aqueous extracts of Desmostachya bipinnata leaves in rodents. In spite of extensive literature available on some components of this plant, there is no known data regarding the pharmacological evaluation on anti-anxiety activity. Thus, this study was intended to performanti-anxiety in experimental animal models.

MATERIALS AND METHODS

Animals

Wistar rats (180±20g) of either sex were procured from institutional animal house and they were retained in the groups of six under the standard laboratory conditions (Temp 23±2 °C, relative humidity 50-60% and 12:12 h light–dark cycle), with standard pellet diet (Amrut brand) and water ad libitum. Experiments were performed only after the animals had acclimated to the laboratory conditions for at least seven days. The experimental protocol was approved by institutional animal ethics committee (1757/PO/RcbBt/CPCSEA).

Plant material collection and extraction

The leaves of Desmostachya Bipinnata were collected cleaned, reduced to small fragments, air dried under shade at room temperature and coarsely powdered in a mixer. The powdered material was taken up for alcoholic extraction by taking 250 ml beaker containing 200 ml of alcohol. The contents were mixed well and boiled up to 50-60 °C for 4-5 h. Further, the extract was filtered with whatmann filter paper. The filtrate was boiled until the concentrated residue is formed. The aqueous extract was prepared by taking 20 gms of finely cut leaves into 250 ml beaker containing 200 ml of water and was boiled up to 80-100 °C for 4-5 h. Further, the extract was filtered with whatmann filter paper. The filtrate was boiled until the concentrated residue is formed.

Results: The results infer that reduced aversion fear elicits anti-anxiety activity.

Conclusion: It was concluded that alcoholic and aqueous extracts of Desmostachya bipinnata leaves are having anti-anxiety activity among which alcoholic extract of Desmostachya bipinnata leaves showing more significant activity over the aqueous extract.

Methods: Antianxiety activity was screened by different methods like elevated plus maze model and actophotometer.

Keywords: Desmostachya bipinnata, Antianxiety activity, Elevated plus maze, Actophotometer
Group I-Control group received distilled water (1 ml p. o).
Group II-Standard group received Diazepam (10 mg/kg i. p).
Group III (AQEDB-1)-Test group received an aqueous extract of Desmostachyabipinnata (200 mg/kg p. o).
Group IV (AQEDB-2)-Test group received aqueous extract of Desmostachyabipinnata (400 mg/kg p. o).
Group V (ALEDB-1)-Test group received an alcoholic extract of Desmostachyabipinnata (200 mg/kg p. o).
Group VI (ALEDB-2)-Test group received an alcoholic extract of Desmostachyabipinnata (400 mg/kg p. o).

Anti-anxiety activity by elevated plus maze (EPM) model

The apparatus comprises of two open (3x5x5 cm) and two closed arms (30x5x15 cm) that extend from a common central platform (5x5 cm). The entire maze is elevated to a height of 50 cm above the ground level. Rats weighing (150-200 gms) were housed in a pair of 10 d prior to the test in the apparatus and were handled by the investigator on alternate days to reduce stress. 30and 60 min following oral administration of the drugs, each rat was located in the centre of the maze which is facing enclosed arms. During 5 min session, a number of entries into open arm and time spent in it was noted. The procedure was conducted preferably in a sound attenuated environment.

Anti-anxiety activity by elevated plus maze (EPM) model

The locomotor activity can be easily studied with the help of actophotometer [17], after the drug treatments rats are placed individually in the activity cage for 10 min. Note the basal activity score of all the animals. After 30 min re-test each rat for activity scores for 10 min. Note the difference in the activity, before and after drug treatment. Calculate percent decrease in motor activity.

Statistical analysis

The values were expressed as mean±SEM and data were analyzed using one-way ANOVA followed by T-test. Two sets of comparison had been done. i.e. Normal control Vs All treated groups. Differences between groups were considered significant at P<0.001 and P<0.05 level.

### Table 1: Data obtained from elevated plus maze experiment

| Groups                     | Dose (mg/kg) | No of entries | Time spent in time spent in |
|----------------------------|--------------|---------------|-----------------------------|
|                            |              | Open Arm      | Closed Arm                  | Open Arm  | Closed Arm |
| Control (Distilled Water)  | ---          | 2.36±1.25"    | 2.48±1.58"                 | 30.12±8.05" | 266.45±21.47" |
| Standard (Diazepam)        | 10 mg/kg     | 4.21±0.65"    | 4.01±1.45"                 | 26.88±1.36" | 170.55±30.54" |
| AQEDB-1                    | 200 mg/kg    | 3.95±0.87"    | 3.10±1.44"                 | 30.54±1.15" | 150.20±22.36" |
| ALEDDB-2                   | 400 mg/kg    | 3.50±1.54"    | 3.14±0.24"                 | 28.23±1.65" | 165.41±19.32" |
| ALEDDB-1                   | 200 mg/kg    | 3.52±1.87"    | 2.98±1.72"                 | 32.14±1.74" | 162.22±24.65" |
| ALEDDB-2                   | 400 mg/kg    | 3.02±4.44"    | 2.71±1.05"                 | 25.21±0.89" | 154.36±32.12" |

Values expressed mean±SEM "**p<0.001, *p<0.01, p<0.05 when compared to Standard group. One-way ANOVA followed by Dunnett’s test.

### RESULTS

### Elevated plus maze (EPM) model

From the experiment, it was observed that rats given aqueous and alcohol soluble fraction at a dose of 200 mg/kg and 400 mg/kg body weight, stayed more time in open arm of Elevated plus Maze apparatus in comparison to standard and control group. Moreover, they also stayed less time in closed arm of Elevated plus Maze apparatus in comparison to standard and control group. The values obtained from these fraction were statistically significant (p<0.05).

### Actophotometer model

Anxiolytic property of aqueous and alcoholic extracts of Desmostachyabipinnata was studied at a dose of 200 and 400 mg/Kg, using Actophotometer model.

The percentage of reduction in locomotor activity with diazepam (10 mg/kg i. p) after 1 hour is 80 % i.e. there is significant (P<0.001) decrease in locomotor activity compare to control, whereas dose of AQEDB and ALEDDB (200 and 400 mg/kg i. p) showed dose dependent decrease in locomotor activity that is 78.3% and 75.8% respectively when compared to standard. The values are highly significant (P<0.001).

### Table 2: Effect of extracts of Desmostachyabipinnata on Locomotor activity

| S. No. | Groups   | Dose (mg/kg) | Locomotor activity in 10 min |
|--------|-----------|--------------|------------------------------|
|        |           |              | Before | After | % change in activity |
| 1      | Control   | -            | 245.1±2.35.44" | -- | -- |
| 2      | Standard  | 30           | 27.32±45.02"   | 82.33±10.69" | 68.5|
| 3      | AQEDB-1   | 200          | 36.52±43.65"   | 79.06±9.26"  | 78.3|
| 4      | AQEDB-2   | 400          | 374.11±36.54"  | 70.65±8.55"  | 81.2|
| 5      | ALEDDB-1  | 200          | 286.60±36.88"  | 69.05±9.88"  | 75.8|
| 6      | ALEDDB-2  | 400          | 300.3±39.65"   | 60.65±5.64"  | 80 |

Values expressed mean±SEM "**p<0.001, *p<0.01, p<0.05 when compared to standard group. One-way ANOVA followed by Dunnett’s test. The results are expressed as mean±SEM. Differences in mean values between groups were analyzed by one-way analysis of variance (ANOVA). Statistical significance was assessed as p<0.05.

### DISCUSSION

The anti-anxiety activity of Desmostachyabipinnata was evaluated by using a widely used model like elevated plus-maze. Mean a number of entries and time spent by rats in open arms amongst aqueous and alcoholic extracts of Desmostachyabipinnata significantly increased mean number of entries and mean time spent by rats in open arms of elevated plus maze apparatus at the dose of 200 mg/kg with respect to control, thereby showing anti-anxiety activity. Desmostachyabipinnata contains different chemical constituents like alkaloids, Carbohydrates, Saponins, Tannins, Phytosterols and Phenolic compounds, lignin, flavonoids, protein and free amino acids [18].

It was earlier reported that several essential oils that are obtained from florae are engaged to balance emotions, develop physical and mental well-being [19] by different mechanisms. Therefore, essential oils that are present in the extracts of Desmostachyabipinnata [20] may be responsible for the anti-anxiety activity.
Further, the anxiolytic effect of flavonoids has been attributed to its effect on the central nervous system and benzodiazepine receptors [21]. It may be possible that the mechanism of anxiolytic action of AQEDB and ALEDB could be due to the binding of any of these phytochemicals to the GABA/BDZ complex. So the anxiolytic activity of AQEDB and ALEDB might involve an action on GABAergic transmission or effects on serotonergic transmission or due to its mixed aminergic potentiating effect.

Spontaneous locomotor activity is considered as an index of alertness and can be helpful to confirm the general depressive activity of any drug. The reduction in motor activity indicates the level of CNS excitability and this may be related to sedation due to CNS depression. However, in the present study, the AQEDB and ALEDB was found to have decreased effect on the locomotor activity in actophotometer.

CONCLUSION

The results obtained in this study indicate that the alcoholic and aqueous extracts fractions of the leaves of Desmostachyabipinnata have significant CNS Depressant and Anxiolytic activities in animal model systems. The medicinal values of the plant leaves may be related to their constituent phytochemicals. So, further detailed investigations are needed to isolate and identify the active compounds present in the plant extract and its various fractions. It will help in the development of novel and safe drugs for the treatment of different types of CNS disorders.
